Two measures of concentration that are useful for the study of colligative properties, because they indicate the relative numbers of solute and solvent molecules, are mole fraction and molality. The measure of composition *mole fraction*, x, was first introduced in Section 4.8, where we saw that it is the ratio of the amount (in moles) of a species to the total amount of all the species present in a mixture. For our purposes we write

$$\text{Mole fraction of solute} = \frac{\text{amount of solute (mol)}}{\text{total amount of solute and solvent (mol)}}$$

or

$$x_{\text{solute}} = \frac{n_{\text{solute}}}{n_{\text{solute}} + n_{\text{solvent}}} \qquad (3)^*$$

The **molality,** b, of a solute is the amount of solute species (in moles) in a solution divided by the mass of the solvent (in kilograms):

$$\text{Molality of solute} = \frac{\text{amount of solute (mol)}}{\text{mass of solvent (kg)}}$$

or

$$b_{\text{solute}} = \frac{n_{\text{solute}}}{m_{\text{solvent}}} \qquad (4)^*$$

A note on good practice: The IUPAC *symbol* for molality is either m or b; we prefer the latter because it avoids confusion with m for mass (as in Eq. 4). The *units* of molality are moles of solute per kilogram of solvent ($\text{mol}\cdot\text{kg}^{-1}$); these units are often (but unofficially) denoted m (for example, a 1 m $NiSO_4$(aq) solution) and read "molal." Because contexts differ, there is little chance of m for molality being confused with m for meter. Note that

when we refer to the molality (or molarity) of a specific solute we include its chemical formula. Remember from Section A that units (such as m) are denoted by Roman letters that distinguish them from the physical quantity to which they refer (such as b).

Like mole fraction but unlike molarity, the molality is independent of temperature. Note the emphasis on *solvent* in the definition. To prepare 1 m $NiSO_4$(aq), we dissolve 1 mol $NiSO_4$ in 1 kg of water (Fig. 9.26).

FIGURE 9.26 The steps taken to prepare a solution of a given molality. First (left), the required masses of solute and solvent are measured out. Then (right), the solute is dissolved in the solvent. Compare this procedure with that for preparing a solution of given molarity (see Fig. G.8).

EXAMPLE 9.5 Calculating the molality of a solute

What is the molality of the sugar fructose ($C_6H_{12}O_6$) in a solution prepared by dissolving 90.5 g of fructose in 250. g of water?

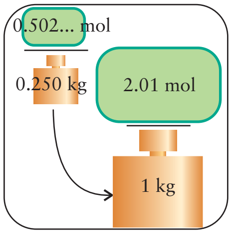
PLAN Convert the mass of fructose into amount of $C_6H_{12}O_6$ in moles, express the mass of water in kilograms, and then divide the amount of solute by the mass of solvent.

SOLVE

From $b_{solute} = n_{solute}(\text{mol})/m_{solvent}(\text{kg})$ and $n_{solute} = m_{solute}/M_{solute}$,

$$b(C_6H_{12}O_6) = \frac{(90.5\ \text{g})/(180.15\ \text{g·mol}^{-1})}{0.250\ \text{kg}}$$

$$= 2.01\ \text{mol·kg}^{-1}$$



We report this molality as 2.01 m $C_6H_{12}O_6$(aq).

Self-Test 9.8A Calculate the molality of $ZnCl_2$ in a solution prepared by dissolving 4.11 g of $ZnCl_2$ in 150. g of water.

[***Answer:*** 0.201 mol·kg^{-1}]

Self-Test 9.8B Calculate the molality of $KClO_3$ in a solution prepared by dissolving 7.36 g of $KClO_3$ in 200. g of water.

TOOLBOX 9.1 HOW TO USE THE MOLALITY

CONCEPTUAL BASIS

The molality is the concentration of solute in moles per kilogram of solvent. Its value is independent of the temperature and is directly proportional to the relative numbers of solute and solvent molecules in the solution. To convert molarity to molality, we note that the former is defined in terms of the volume of the solution, so we convert that overall volume to the mass of solvent present.

PROCEDURE

When working with molality it is helpful to keep its definition ($b_{solute} = n_{solute}/m_{solvent}$) in mind.

1 Calculating the mass of solute in a given mass of solvent from the molality

Step 1 Calculate the amount of solute molecules, n_{solute}, present in a given mass of solvent, $m_{solvent}$, by rearranging the equation defining molality (Eq. 4) into

$$n_{solute} = b_{solute} \times m_{solvent}$$

Step 2 Use the molar mass of the solute, M_{solute}, to find the mass of the solute from its amount:

$$m_{solute} = n_{solute}M_{solute}$$

2 Calculating the molality from a mole fraction

Step 1 Consider a solution composed of a total of 1 mol of molecules. If the mole fraction of the solute is x_{solute}, the amount of solute molecules in a total of 1 mol of molecules is

$$n_{solute} = x_{solute} \times n_{total} = x_{solute} \times (1\ \text{mol}) = x_{solute}\ \text{mol}$$

Step 2 If there is only one solute, the mole fraction of solvent molecules is $1 - x_{solute}$. The amount of solvent molecules in a total of 1 mol of molecules is then $n_{solvent} = (1 - x_{solute})$ mol. Convert this amount into mass in grams by using the molar mass of the solvent, $M_{solvent}$:

$$m_{solvent} = n_{solvent}M_{solvent} = \{(1 - x_{solute})\ \text{mol}\}M_{solvent}$$

and then convert grams into kilograms.

Step 3 Calculate the molality of the solute by dividing the amount of solute molecules (step 1) by the mass of solvent in kilograms (step 2).

Example 9.6 shows how to carry out this conversion.

3 Calculating the mole fraction from the molality

Step 1 Consider a solution containing exactly 1 kg of solvent. Convert that mass of solvent into an amount

of solvent molecules, $n_{solvent}$, by using the molar mass, $M_{solvent}$, of the solvent:

$$n_{solvent} = \frac{1\ \text{kg}}{M_{solvent}} = \frac{10^3\ \text{g}}{M_{solvent}}$$

We know the amount of solute molecules, n_{solute}, in 1 kg of solvent:

$$n_{solute} = b_{solute} \times (1\ \text{kg})$$

Step 2 Calculate the mole fractions from the amounts of solvent and solute molecules:

$$x_{solute} = \frac{n_{solute}}{n_{solute} + n_{solvent}}$$

4 Calculating the molality, given the molarity

The conversion is more involved because the molality is defined in terms of the mass of *solvent* but the molarity is defined in terms of the volume of *solution*. To carry out the conversion we need to know the density of the solution.

Step 1 Calculate the total mass of exactly 1 L (10^3 mL) of solution by using the density, d, of the solution (not the solvent):

$$m_{solution} = d \times (10^3\ \text{mL})$$

Step 2 The molarity, c_{solute}, gives the amount of solute in 1 L of solution.

$$n_{solute} = c_{solute} \times (1\ \text{L})$$

Use the molar mass of the solute to convert that amount into the mass of solute present in 1 L of solution:

$$m_{solute} = n_{solute}M_{solute} = c_{solute} \times (1\ \text{L}) \times M_{solute}$$

Step 3 Subtract the mass of solute (step 2) from the total mass (step 1) to find the mass of solvent in 1 L of solution,

$$m_{solvent} = m_{solution} - m_{solute}$$

and express the mass of solvent in kilograms.

Step 4 The molality is the amount of solute in 1 L of solution (given by the molarity) divided by the mass of the solvent in kilograms (step 3).

See Example 9.7.

EXAMPLE 9.6 Calculating a molality from a mole fraction

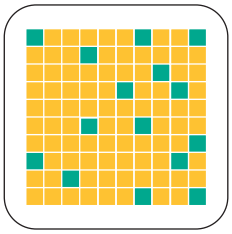
What is the molality of benzene, C_6H_6, dissolved in toluene, $C_6H_5CH_3$, in a solution for which the mole fraction of benzene is 0.150?

PLAN Use procedure 2 in Toolbox 9.1.

SOLVE

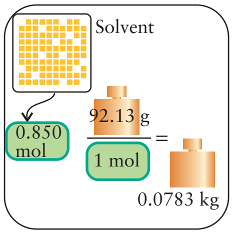
Step 1 Find the amount of solute molecules in a total of exactly 1 mol of solution molecules from $n_{solute} = x_{solute} \times n_{total}$:

$$n_{benzene} = 0.150 \times 1\ \text{mol} = 0.150\ \text{mol}$$



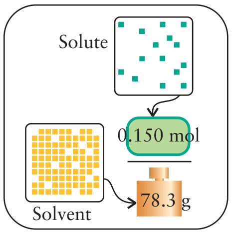
Step 2 Find the mass of solvent present from $m_{solvent} = \{(1 - x_{solute})\ \text{mol}\}M_{solvent}$ and convert to kilograms:

$$m_{toluene} = (1 - 0.150)\ \text{mol} \times (92.13\ \text{g·mol}^{-1}) \times \frac{1\ \text{kg}}{10^3\ \text{g}} = 0.850 \times 92.13 \times 10^{-3}\ \text{kg}\ (= 0.0783\ \text{kg})$$



Step 3 Calculate the molality of solute from $b_{solute} = n_{solute}/m_{solvent}$:

$$b(C_6H_6) = \frac{0.150\ \text{mol}}{0.850 \times 92.13 \times 10^{-3}\ \text{kg}} = 1.92\ \text{mol·kg}^{-1}$$



Self-Test 9.9A Calculate the molality of toluene dissolved in benzene, given that the mole fraction of toluene is 0.150. The molar mass of benzene is 78.11 g·mol^{-1}.

[***Answer:*** 2.26 mol·kg^{-1}]

Self-Test 9.9B Calculate the molality of methanol in aqueous solution, given that the mole fraction of methanol is 0.250.

EXAMPLE 9.7 Converting molarity into molality

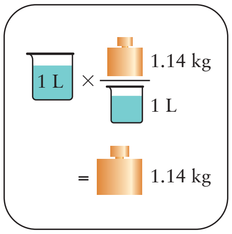
Find the molality of sucrose, $C_{12}H_{22}O_{11}$, in 1.06 M $C_{12}H_{22}O_{11}$(aq), which is known to have density 1.14 g·mL^{-1}.

Anticipate The mass of 1 L of aqueous solution is close to 1 kg, so the numerical value of the molality can be expected to be close to that of the molarity, but with different units, of course.

SOLVE Use procedure 4 in Toolbox 9.1.

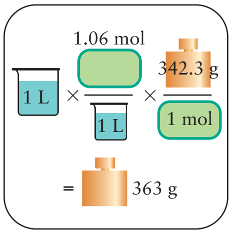
Step 1 Find the mass of exactly 1 L (10^3 mL) of solution from $m = d \times (10^3 \text{ mL})$.

$$m_{\text{solution}} = (1.14 \text{ g·mL}^{-1}) \times (10^3 \text{ mL}) = 1.14 \times 10^3 \text{ g}$$



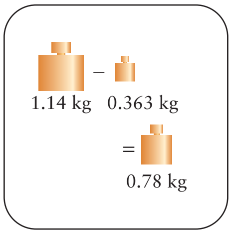
Step 2 Find the mass of solute in exactly 1 L of solution from $m_{\text{solute}} = n_{\text{solute}}M_{\text{solute}} = c_{\text{solute}} \times (1 \text{ L}) \times M_{\text{solute}}$.

$$m_{\text{sucrose}} = (1.06 \text{ mol·L}^{-1}) \times (1 \text{ L}) \times (342.3 \text{ g·mol}^{-1}) = 1.06 \times 342.3 \text{ g} = 363 \text{ g}$$



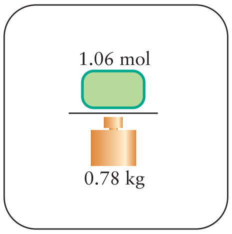
Step 3 Find the mass of water present in exactly 1 L of solution from $m_{\text{water}} = m_{\text{solution}} - m_{\text{solute}}$.

$$m_{\text{water}} = 1140 - 363 \text{ g} = 7.8 \times 10^2 \text{ g, or } 0.78 \text{ kg}$$



Step 4 From $b_{\text{solute}} = n_{\text{solute}}/m_{\text{solvent}}$,

$$b(C_{12}H_{22}O_{11}) = \frac{1.06 \text{ mol}}{0.78 \text{ kg}} = 1.4 \text{ mol·kg}^{-1}$$



Evaluate As expected, the numerical value of the molality of the sucrose, 1.4 (in mol·kg^{-1}), is close to the numerical value of its molarity, 1.06 (in mol·L^{-1}).

Self-Test 9.10A Battery acid is 4.27 M H_2SO_4(aq) and has a density of 1.25 g·cm^{-3}. What is the molality of H_2SO_4 in the solution?

[***Answer:*** 5.14 *m* H_2SO_4(aq)]

Self-Test 9.10B The density of 1.83 M NaCl(aq) is 1.07 g·cm^{-3}. What is the molality of NaCl in the solution?

The molality of a solute in a solution is the amount (in moles) of solute divided by the mass (in kilograms) of solvent used to prepare the solution.

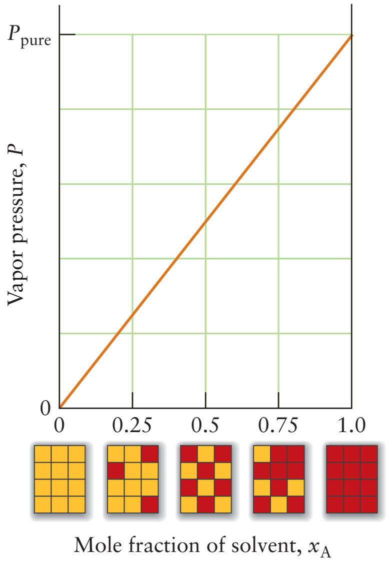


FIGURE 9.27 Raoult's law predicts that the vapor pressure of a solvent in a solution should be proportional to the mole fraction of the solvent molecules. The horizontal axis shows the mole fraction of the red molecules of substance A in the pure solute, three different solutions, and pure solvent, pictured below the graph. The vapor pressure of pure A is marked as P_{pure}. The solute in this solution is nonvolatile, so it does not contribute to the vapor pressure.

9.15 Vapor-Pressure Lowering

The French scientist François-Marie Raoult, who spent much of his life measuring vapor pressures, discovered that *the vapor pressure of a solvent is proportional to its mole fraction in a solution*. This statement, which is called **Raoult's law,** is normally written

$$P = x_{solvent} P_{pure} \qquad (4)^*$$

where P is the vapor pressure of the solvent in the solution, $x_{solvent}$ is the mole fraction of the solvent, and P_{pure} is the vapor pressure of the pure solvent (Fig. 9.27).

What does this equation tell us? The vapor pressure of the solvent is directly proportional to the mole fraction of solvent molecules in the solution. For instance, if 9 out of 10 of the molecules present in a solution are solvent molecules, then the vapor pressure of the solvent is nine-tenths the vapor pressure of the pure solvent for the temperature of interest.

EXAMPLE 9.8 Using Raoult's law

Calculate the vapor pressure of water at 20.°C in a solution prepared by dissolving 10.00 g of the nonelectrolyte sucrose, $C_{12}H_{22}O_{11}$, in 100.0 g of water.

Anticipate Expect a lower vapor pressure when the solute is present. However, the vapor pressure is not lowered very much by a solute, so we should expect a value slightly below that of pure water, which Table 9.3 shows is 17.54 Torr at 20.°C.

PLAN Calculate the mole fraction of the solvent (water) in the solution and then apply Raoult's law. To use Raoult's law, we need the vapor pressure of the pure solvent (Table 9.2 or 9.3).

SOLVE

Find the amount (in moles) of each species from the molar masses of solute and solvent and $n = m/M$:

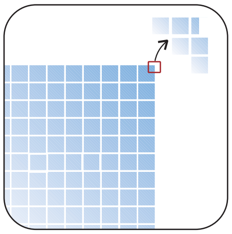
$$\text{Amount of } C_{12}H_{22}O_{12} = \frac{10.00\text{ g}}{342.3\text{ g}\cdot\text{mol}^{-1}} = \frac{10.00}{342.3}\text{ mol}$$

$$(=0.02921\text{ mol})$$

$$\text{Amount of } H_2O = \frac{100.0\text{ g}}{18.02\text{ g}\cdot\text{mol}^{-1}} = \frac{100.0}{18.02}\text{ mol}$$

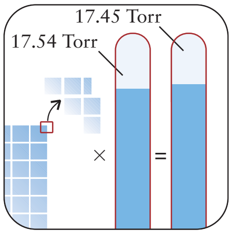
$$(=5.549\text{ mol})$$

Calculate the mole fraction of solvent from $x_{solvent} = n_{solvent}/(n_{solute} + n_{solvent})$:



$$x_{water} = \frac{\left(\frac{100.0}{18.02}\right)\text{ mol}}{\left(\frac{10.00}{342.3}\right)\text{ mol} + \left(\frac{100.0}{18.02}\right)\text{ mol}} \quad (=0.995)$$

Calculate the vapor pressure from $P = x_{solvent}P_{pure}$ and the vapor pressure of pure solvent (Table 9.3):



$$P_{water} = \frac{100.0/18.02}{10.00/342.3 + 100.0/18.02} \times 17.54\text{ Torr}$$
$$= 17.45\text{ Torr}$$

Evaluate As expected, the vapor pressure is slightly less than that of pure water.

Self-Test 9.11A Calculate the vapor pressure of water at 90.°C for a solution prepared by dissolving 5.00 g of glucose ($C_6H_{12}O_6$) in 100. g of water. The vapor pressure of pure water at 90.°C is 524 Torr.

[***Answer:*** 521 Torr]

Self-Test 9.11B Calculate the vapor pressure of ethanol in kilopascals (kPa) at 19°C for a solution prepared by dissolving 2.00 g of cinnamaldehyde, C_9H_8O, in 50.0 g of ethanol, C_2H_5OH. The vapor pressure of pure ethanol at that temperature is 5.3 kPa.

A hypothetical solution that obeys Raoult's law exactly at all concentrations is called an **ideal solution.** In an ideal solution, the interactions between solute and solvent molecules are the same as the interactions between solvent molecules in the pure state and between solute molecules in the pure state. We could summarize this statement by saying that A–A, B–B, and A–B interactions are all the same in an ideal solution. Consequently, the solute molecules mingle freely with the solvent molecules. That is, for an ideal solution, the enthalpy of solution is zero. Solutes that form nearly ideal solutions are often similar in composition and structure to the solvent molecules. For instance, methylbenzene (toluene), $C_6H_5CH_3$, forms nearly ideal solutions with benzene, C_6H_6. Real solutions do not obey Raoult's law at all concentrations; but the lower the solute concentration, the more closely they resemble ideal solutions. Raoult's law is another example of a limiting law (Section 4.4), which in this case becomes increasingly valid as the concentration of the solute approaches zero. A solution that does not obey Raoult's law at a particular solute concentration is called a **nonideal solution.** Real solutions are approximately ideal at solute concentrations below about 0.1 M for nonelectrolyte solutions and 0.01 M for electrolyte solutions. The greater departure from ideality in electrolyte solutions arises from the interactions between ions, which occur over a long distance and hence have a pronounced effect. Unless stated otherwise, we shall assume that all the solutions that we meet are ideal.

Electrolyte solutions, which have ionic solutes, and nonelectrolyte solutions, which have intact molecular solutes, were introduced in Section I.

Thinking point: Laws are useful summaries of experience; but why are *limiting* laws useful?

The lowering of the vapor pressure of a solvent due to the presence of a solute has a thermodynamic basis. We saw in Section 9.2 that at equilibrium, and in the absence of any solute, the molar Gibbs free energy of the vapor is equal to that of the pure liquid solvent. In an ideal solution, a solute increases the disorder and therefore the entropy of the liquid phase: we can no longer be sure that a molecule picked at random from the solution will be a solvent molecule. Because the entropy of the liquid phase is raised by a solute but the enthalpy is left unchanged, overall there is a decrease in the molar Gibbs free energy of the solvent. At equilibrium, the molar Gibbs free energy of the vapor must equal that of the solvent. Because the Gibbs free energy of the solvent has been lowered, for the two phases to remain in equilibrium it follows that the Gibbs free energy of the vapor must be lower, too. Because the Gibbs free energy of a gas depends on its pressure (recall Fig. 9.4), it follows that the vapor pressure also must be lower. In other words, *the vapor pressure of the solvent is lower in the presence of the solute* (Fig. 9.28).

Remember that $G = H - TS$; so if S increases, then G decreases.

The vapor pressure of a solvent is reduced by the presence of a nonvolatile solute: in an ideal solution, the vapor pressure of the solvent is proportional to the mole fraction of solvent.

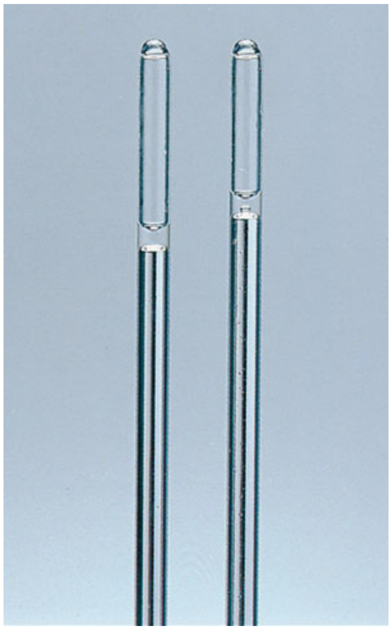


FIGURE 9.28 The vapor pressure of a solvent is lowered by a nonvolatile solute. The barometer tube on the left has a small volume of pure water floating on the mercury. That on the right has a small volume of 10 m NaCl(aq), which has a lower vapor pressure than pure water. Note that the column on the right is depressed less by the vapor in the space above the mercury than the one on the left, showing that the vapor pressure is lower when solute is present.

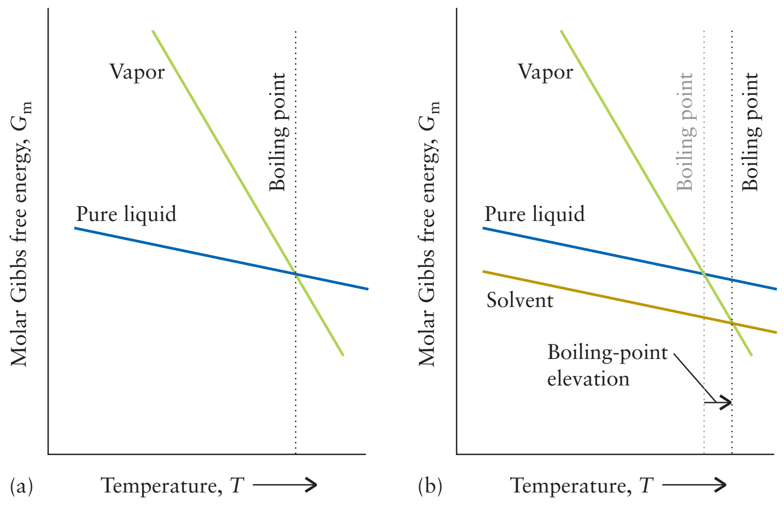

FIGURE 9.29 (a) The molar Gibbs free energy of a liquid and its vapor both decrease with increasing temperature, but that of the vapor decreases more sharply. The vapor is the stable phase at temperatures higher than the point of intersection of the two lines (the boiling point). (b) When a nonvolatile solute is present, the molar Gibbs free energy of the solvent is lowered (an entropy effect), but that of the vapor is left unchanged. The point of intersection of the lines moves to a slightly higher temperature.

9.16 Boiling-Point Elevation and Freezing-Point Depression

Because the presence of a nonvolatile solute lowers the vapor pressure of the solvent, the boiling point of the solvent rises. This increase is called **boiling-point elevation.** The elevation of the boiling point has the same origin as vapor-pressure lowering and is also due to the effect of the solute on the entropy of the solvent.

Figure 9.29a shows how the molar Gibbs free energies of the liquid and vapor phases of a pure solvent vary with temperature. We can understand the form of these diagrams by noting the following points based on the relation $G_m = H_m - TS_m$:

- At low temperatures, $G_m \approx H_m$, and so the line representing G_m of the vapor lies well above that for the liquid because the molar enthalpy of a vapor is considerably greater than that of a liquid.
- The slope of the line is determined by the molar entropy S_m. (Remember that the equation of a straight line is $y = intercept + slope \times x$; here x is T, and the slope is $-S_m$, a negative, downward, slope.) Because the molar entropy of the vapor is much greater than that of the liquid, the line for the vapor slopes down more sharply than that of the liquid.

Above the boiling point, the molar Gibbs free energy of the vapor phase is lower than that of the liquid; therefore, the vapor is the more stable phase. We have already seen that the presence of a solute in the liquid phase of the solvent increases the entropy of the solvent and therefore (through $G_m = H_m - TS_m$ again) lowers its Gibbs free energy. As shown in Fig. 9.29b, the lines representing the molar Gibbs free energies of the liquid solution and the vapor intersect at a higher temperature than they do for the pure solvent, and so the boiling point is higher in the presence of the solute. The increase is usually quite small and is of little practical importance in science. A 0.1 m aqueous sucrose solution, for instance, boils at 100.05°C.

Of broader practical significance is **freezing-point depression,** the lowering of the freezing point of the solvent caused by a solute. For example, seawater freezes about 1°C lower than fresh water. People living in regions with cold winters make use of the depression of the freezing point when they spread salt on icy walkways and roads. The salt lowers the freezing point of water as it produces a salt solution. In the laboratory, chemists make use of the effect to judge the purity of a solid compound: if impurities are present, the compound's melting point is lower than the accepted value. It is commonly said that antifreeze added to car engines is an example of the lowering of freezing point: it is, but it is not a colligative effect, as the concentration is far too high. It is better to think of the ethylene glycol molecules ($HOCH_2CH_2OH$, the common active component) as lying between the water molecules and preventing their linking together to form ice.

Figure 9.30a shows how the molar Gibbs free energies of the liquid and solid phases of a pure solvent vary with temperature. The explanation of the layout of the lines is

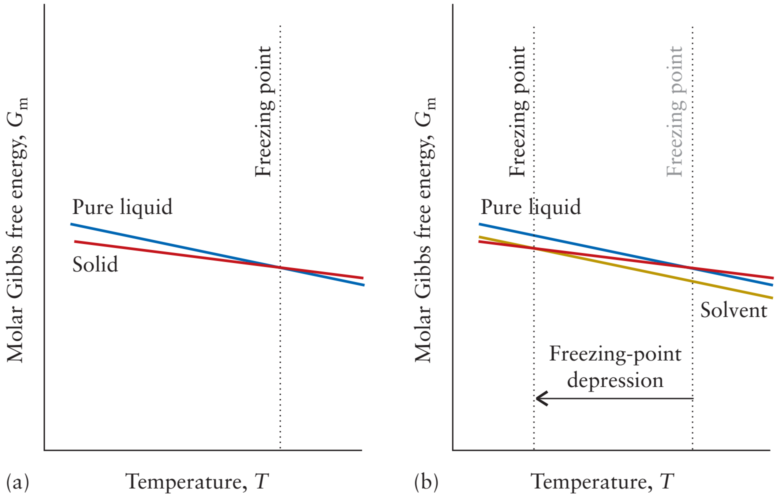

FIGURE 9.30 (a) The molar Gibbs free energy of a solid and its liquid phase both decrease with increasing temperature, but that of the liquid decreases slightly more steeply. The liquid is the stable phase at temperatures higher than the point of intersection of the two lines. (b) When a solute is present, the molar Gibbs free energy of the solvent is lowered (an entropy effect), but that of the solid is left unchanged. The point of intersection of the lines moves to a lower temperature.

similar to that for a liquid and its vapor, but the differences in position and slope are less pronounced:

- At low temperatures, $G_m \approx H_m$, and so the line representing G_m of the liquid lies above that for the solid (but not much because the enthalpies are not as different as for a liquid and a vapor).
- Because the molar entropy of the liquid is greater than that of the solid, the line for the liquid slopes down more sharply than that of the solid (but not much because the entropies are not as different as for a liquid and a vapor).

The solid is the more stable phase below the freezing point, where the molar Gibbs free energy of the solid is lower than that of the liquid. The presence of a solute in the liquid phase of the solvent raises the entropy of the solvent and hence lowers its Gibbs free energy (Fig. 9.30b). However, because the solute is insoluble in the solid solvent, the Gibbs free energy of the solid phase of the solvent is unchanged. The lines representing the molar Gibbs free energies of the liquid and solid phases of the solvent intersect at a lower temperature than they do for the pure solvent, and so the freezing point is lower in the presence of the solute.

It is found empirically and can be justified thermodynamically that the freezing-point depression for an ideal solution is proportional to the molality b of the solute. For a nonelectrolyte solution,

$$\text{Freezing-point depression: } \Delta T_f = k_f \times b_{\text{solute}} \quad \textbf{(5a)}$$

The constant k_f is called the **freezing-point constant** of the solvent; it is different for each solvent and must be determined experimentally (Table 9.8). The effect is quite small: for instance, for a 0.1 m $C_{12}H_{22}O_{11}(aq)$ (sucrose) solution,

$$\text{Freezing-point depression} = (1.86\ \text{K·kg·mol}^{-1}) \times (0.1\ \text{mol·kg}^{-1}) = 0.2\ \text{K}$$

Hence the water in the solution freezes at −0.2°C.

TABLE 9.8 Boiling-Point and Freezing-Point Constants

Solvent	Freezing point (°C)	k_f (K·kg·mol^{-1})	Boiling point (°C)	k_b (K·kg·mol^{-1})
acetone	−95.35	2.40	56.2	1.71
benzene	5.5	5.12	80.1	2.53
camphor	179.8	39.7	204	5.61
carbon tetrachloride	−23	29.8	76.5	4.95
cyclohexane	6.5	20.1	80.7	2.79
naphthalene	80.5	6.94	217.7	5.80
phenol	43	7.27	182	3.04
water	0	1.86	100.0	0.51

Self-Test 9.12A Use the data in Table 9.8 to determine at what temperature a 0.20 mol·kg^{-1} solution of the analgesic codeine, $C_{18}H_{21}NO_3$, in benzene will freeze.

[***Answer:*** 4.5°C]

Self-Test 9.12B Use the data in Table 9.8 to determine at what temperature a 0.050 mol·kg^{-1} solution of the insecticide malathion, $C_{10}H_{19}O_6PS_2$, in camphor will freeze.

In an electrolyte solution, each formula unit contributes two or more ions. Sodium chloride, for instance, dissolves to give Na^+ and Cl^- ions, and both kinds of ions contribute to the depression of the freezing point. The cations and anions contribute nearly independently in very dilute solutions, and so the total solute molality is twice the molality of NaCl formula units. In place of Eq. 5a we write

$$\text{Freezing-point depression: } \Delta T_f = ik_f \times b_{\text{solute}} \qquad \textbf{(5b)*}$$

Here, i, the **van 't Hoff *i* factor,** is determined experimentally. In a very dilute solution (less than about 10^{-3} mol·L^{-1}), when all ions are independent, $i = 2$ for MX salts such as NaCl, $i = 3$ for MX_2 salts such as $CaCl_2$, and so on. For dilute nonelectrolyte solutions, $i = 1$. The i factor is so unreliable, however, that it is best to confine quantitative calculations of freezing-point depression to nonelectrolyte solutions. Even these solutions must be dilute enough to be approximately ideal.

The i factor can be used to help determine the extent to which a substance is dissociated into ions in solution. For example, in dilute solution, HCl has i L 1 in toluene and i L 2 in water. These values suggest that HCl retains its molecular form in toluene but is fully deprotonated in water (deprotonation, the loss of a proton from an acid, is described in Section J). The strength of a weak acid in water can be estimated in this way. In an aqueous solution of a weak acid that is 5% deprotonated (5% of the acid molecules have given up their protons), each deprotonated molecule produces two ions and $i = 0.95 + (0.05 \times 2) = 1.05$.

Because the vapor pressure of a solvent is lowered by the presence of a solute, the elevation of the boiling point of a solvent by a solute can be expressed by an equation similar to Eq. 5b:

$$\text{Boiling-point elevation: } \Delta T_b = ik_b \times b_{\text{solute}} \qquad \textbf{(5c)}$$

The values of k_b, some of which are listed in Table 9.8, must be determined experimentally. Although it is useful to be aware of the dependence of boiling point on concentration, this equation is rarely used because the effect is so small that it is difficult to measure.

Cryoscopy is the determination of the molar mass of a solute by measuring the depression of freezing point that it causes when dissolved in a solvent. Camphor has been used as the solvent for organic compounds because it has a large freezing-point constant; consequently, solutes depress its freezing point significantly. However, this procedure is rarely used in modern laboratories because techniques such as mass spectrometry give far more reliable results (see Major Technique 6, following Chapter 18). The procedure is described in Toolbox 9.2 at the end of Section 9.17.

The presence of a solute lowers the freezing point of a solvent; if the solute is nonvolatile, the boiling point is also raised. The freezing-point depression can be used to calculate the molar mass of the solute. If the solute is an electrolyte, the extent of its dissociation or (for an acid) deprotonation must also be taken into account.

9.17 Osmosis

The name "osmosis" comes from the Greek word for "push."

Osmosis is the flow of solvent through a membrane into a more concentrated solution. The phenomenon can be demonstrated in the laboratory when a solution and the pure solvent are separated by a **semipermeable membrane,** a membrane that permits only certain types of molecules or ions to pass through (Fig. 9.31). Cellulose acetate, for instance, allows water molecules to pass through it, but not solute molecules or ions with their bulky coating of hydrating water molecules. Initially, the heights of the solution

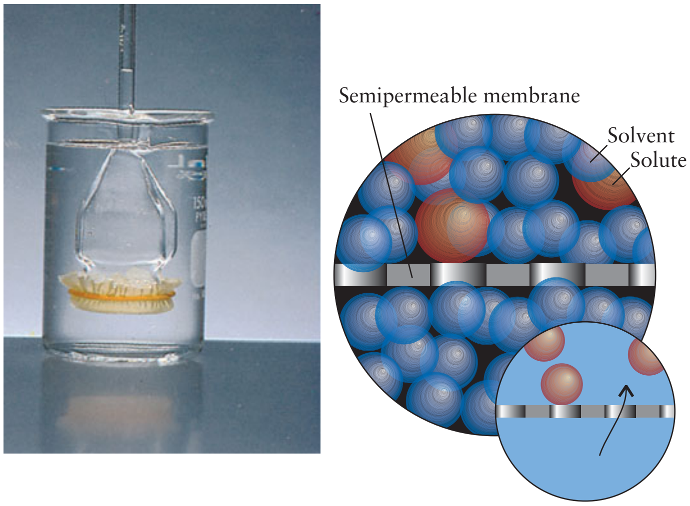

FIGURE 9.31 An experiment to illustrate osmosis. Initially, the tube contained a sucrose solution and the beaker contained pure water: the initial heights of the two liquids were the same. At the stage shown here, water has passed into the solution through the membrane by osmosis, and the level of solution in the tube has risen above that of the pure water. The large inset shows the molecules of pure solvent (below the membrane) tending to join those in the solution (above the membrane) because the presence of solute molecules there has led to increased disorder. The small inset shows just the solute molecules; the arrow shows the direction of flow of solvent molecules.

and the pure solvent shown in the illustration are the same. However, the level of the solution inside the tube begins to rise as pure solvent passes through the membrane into the solution. At equilibrium, the pressure exerted by the higher level of the column of solution is sufficiently great that the rate of flow of molecules through the membrane is the same in each direction, and so the net flow is zero. The pressure needed to stop the flow of solvent is called the **osmotic pressure,** Π (the Greek uppercase letter pi). The greater the osmotic pressure, the greater the height of the solution needed to reduce the net flow to zero.

The pressure exerted by a vertical column of liquid is proportional to its height: see Eq. 2 in Section 4.2.

Life depends on osmosis, which is the most important of all the colligative properties. Biological cell walls act as semipermeable membranes that allow water, small molecules, and hydrated ions to pass (Fig. 9.32). However, they block the passage of the enzymes and proteins that have been synthesized within the cell. The higher concentration of solutes within a cell compared to the solution outside the cell gives rise to an osmotic pressure, and water passes into the more concentrated solution in the interior of the cell, carrying small nutrient molecules with it. This influx of water also keeps the cell turgid (swollen). When the water supply is cut off, the turgidity is lost and the cell becomes dehydrated. In a plant, this dehydration results in wilting. Salted meat is preserved from bacterial attack by osmosis. In this case, the concentrated salt solution dehydrates—and kills—the bacteria by causing water to flow out of them.

Because osmosis is a thermodynamic property, we can expect it to be related to the effect of the solute on the enthalpy and entropy of the solution: solvent flows until the molar Gibbs free energy of the solvent is the same on each side of the membrane. We have already seen several times that a solute lowers the molar Gibbs free energy of the solution below that of the pure solvent, and solvent therefore has a tendency to pass into the solution (Fig. 9.33).

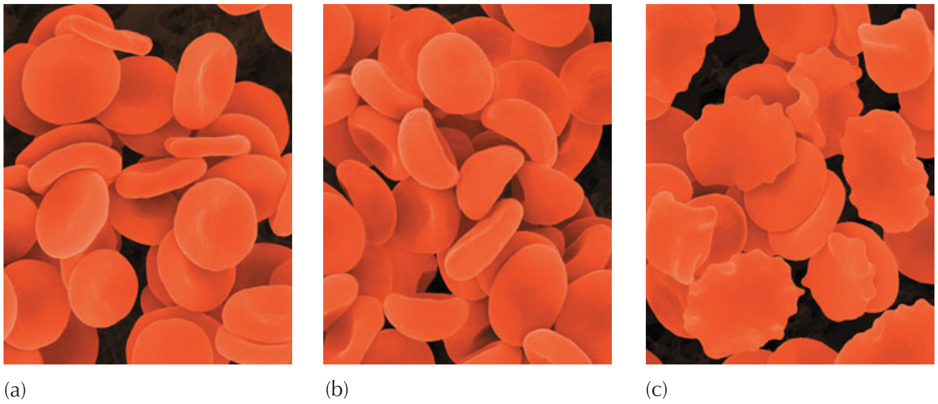

FIGURE 9.32 (a) Red blood cells need to be in a solution of the correct solute concentration if they are to function properly. (b) When the solution is very dilute, too much water passes into them and they burst. (c) When the solution is too concentrated, water flows out of them and they shrivel up.

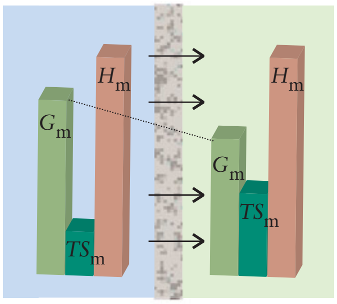

FIGURE 9.33 On the left of the semipermeable membrane is the pure solvent with its characteristic molar enthalpy, entropy, and Gibbs free energy. On the right is the solution. The molar Gibbs free energy of the solvent is lower in the solution (an entropy effect), and so there is a spontaneous tendency for the solvent to flow into the solution.

The same van 't Hoff responsible for the i factor showed that the osmotic pressure of a dilute solution is related to the molarity, c, of the solute in the solution:

$$\Pi = iRTc_{\text{solute}} \qquad (6)^*$$

where i is the i factor (Section 9.16), R is the gas constant, and T is the temperature. This expression is now known as the **van 't Hoff equation**. Notice that the osmotic pressure depends only on temperature and the total molar concentration of solute. It is independent of the identities of both the solute and the solvent. However, in an apparatus like that shown in Fig. 9.31, the height to which the solvent is driven does depend on the identity of the solvent, because that height depends on its density (Fig. 9.34).

The van 't Hoff equation is used to determine the molar mass of a solute from osmotic pressure measurements. This technique, which is called **osmometry,** involves the determination of the osmotic pressure of a solution prepared by making up a known volume of solution having a known mass of solute with an unknown molar mass. If we know the mass of solute in a given volume of solution and have determined the amount of solute in that volume by using the osmotic pressure to determine the molarity, then we can work out the molar mass by dividing the mass by the amount ($M = m/n$). Osmometry is very sensitive, even at low concentrations, and is commonly used to determine very large molar masses, such as those of polymers.

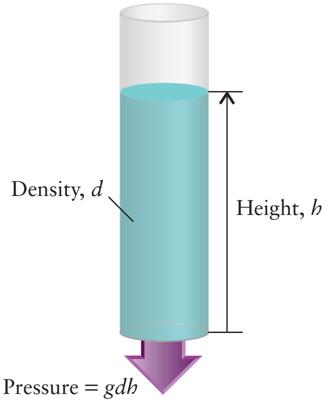

FIGURE 9.34 The pressure at the base of a column of fluid is equal to the product of the acceleration of free fall, g, the density, d, of the liquid, and the height, h, of the column.

Self-Test 9.13A What is the osmotic pressure of 0.0100 M KCl(aq) at 298 K? (Assume $i = 2$.)

[***Answer:*** 0.489 atm]

Self-Test 9.13B What is the osmotic pressure of a 0.120 M sucrose solution at 298 K?

TOOLBOX 9.2 HOW TO USE COLLIGATIVE PROPERTIES TO DETERMINE MOLAR MASS

CONCEPTUAL BASIS

The lowering of freezing point and the generation of osmotic pressure both depend on the total concentration of solute particles. Therefore, by using these colligative properties to determine the amount of solute present, and knowing its mass, we can infer its molar mass.

PROCEDURE

1 Cryoscopy

Step 1 Convert the observed freezing-point depression, ΔT_f, into solute molality b by writing Eq. 5b in the form

$$b_{\text{solute}} = \frac{\Delta T_f}{ik_f}$$

Take the freezing-point constant from Table 9.8.

Step 2 Calculate the amount of solute, n_{solute} (in moles), in the sample by multiplying the molality by the mass of solvent, m_{solvent} (in kilograms):

$$n_{\text{solute}} = b_{\text{solute}} \times m_{\text{solvent}}$$

Step 3 Determine the molar mass of the solute by dividing the given mass of solute, m_{solute} (in grams), by the calculated amount in moles (step 2).

$$M_{\text{solute}} = \frac{m_{\text{solute}}}{n_{\text{solute}}}$$

This procedure is illustrated in Example 9.9.

2 Osmometry

Step 1 Convert the observed osmotic pressure into solute molarity (c, not molality) by writing Eq. 6 in the form

$$c_{\text{solute}} = \frac{\Pi}{iRT}$$

In some cases, it may be necessary to calculate the osmotic pressure from the height, h, of the solution (in an apparatus like that in Fig. 9.31) by using $\Pi = gdh$, where d is the density of the solution and g is the acceleration of free fall (see inside back cover).

Step 2 Because molarity is defined as $c_{\text{solute}} = n_{\text{solute}}/V$, where n_{solute} is the amount of solute (in moles) and V is the volume of solution (in liters), calculate the amount of solute from:

$$n_{\text{solute}} = c_{\text{solute}}V$$

Step 3 Determine the molar mass of the solute by dividing the given mass of solute, m_{solute} (in grams), by its amount (step 2), as in the procedure for cryoscopy.

This procedure is illustrated in Example 9.10.

EXAMPLE 9.9 Determining molar mass cryoscopically

The addition of 0.24 g of sulfur to 100. g of the solvent carbon tetrachloride lowers the solvent's freezing point by 0.28°C. Sulfur is known to exist in molecular form. What is the molar mass and molecular formula of sulfur?

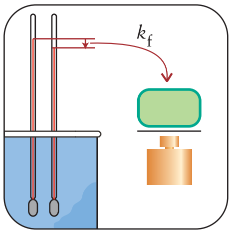
Anticipate You might already be aware that sulfur forms crownlike S_8 molecules.

PLAN Use the procedure for cryoscopy in Toolbox 9.2. Sulfur is a nonelectrolyte, so $i = 1$.

SOLVE

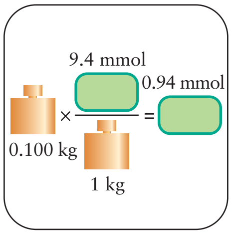
Step 1 Assume that $i = 1$. Then find the molality of solute from $b_{solute} = \Delta T/ik_f$.

$$b_{solute} = \frac{0.28\ \text{K}}{29.8\ \text{K·kg·mol}^{-1}} = \frac{0.28}{29.8}\ \text{mol·kg}^{-1}$$



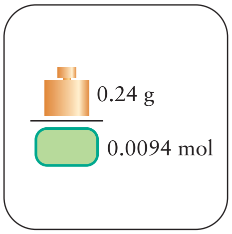
Step 2 Calculate the amount of solute present from $n_{solute} = b_{solute}m_{solvent}$.

$$n(S_x) = (0.100\ \text{kg}) \times \frac{0.28}{29.8}\ \text{mol·kg}^{-1} = \frac{0.100 \times 0.28}{29.8}\ \text{mol}$$



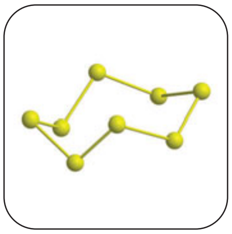
Step 3 Determine the molar mass of the solute from $M_{solute} = m_{solute}/n_{solute}$.

$$M(S_x) = \frac{0.24\ \text{g}}{(0.100 \times 0.28/29.8)\ \text{mol}} = 2.6 \times 10^2\ \text{g·mol}^{-1}$$



Use the molar mass of atomic sulfur (32.01 g·mol^{-1}) to find the value of x in the molecular formula S_x.

$$x = \frac{2.6 \times 10^2\ \text{g·mol}^{-1}}{32.1\ \text{g·mol}^{-1}} = 8.1$$



Evaluate Elemental sulfur is indeed composed of S_8 molecules.

Self-Test 9.14A When 250. mg of eugenol, the molecular compound responsible for the odor of oil of cloves, was added to 100. g of camphor, it lowered the freezing point of camphor by 0.62°C. Calculate the molar mass of eugenol.

[***Answer:*** $1.6 \times 10^2\ \text{g·mol}^{-1}$ (actual: 164.2 g·mol^{-1})]

Self-Test 9.14B When 200. mg of linalool, a fragrant molecular compound found in cinnamon oil from Sri Lanka, was added to 100. g of camphor, it lowered the freezing point of camphor by 0.51°C. What is the molar mass of linalool?

EXAMPLE 9.10 Using osmometry to determine molar mass

The osmotic pressure due to 2.20 g of polyethylene (PE) dissolved in enough benzene to produce 100.0 mL of solution was 1.10×10^{-2} atm at 25°C. Calculate the average molar mass of the polymer, which is a nonelectrolyte.

Anticipate Because so many atoms are linked together in each polymer molecule, we should expect a high molar mass.

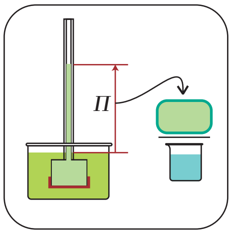
PLAN Use the procedure for osmometry in Toolbox 9.2. Because polyethylene is a nonelectrolyte, $i = 1$. Use R in the units that match the data: in this case, liters and atmospheres.

SOLVE

Step 1 From $c_{\text{solute}} = \Pi/iRT$,

$$c = \frac{1.10 \times 10^{-2}\ \text{atm}}{(0.0821\ \text{L·atm·K}^{-1}\text{·mol}^{-1}) \times (298\ \text{K})}$$

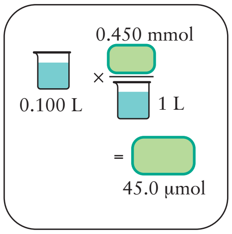
$$= \frac{1.10 \times 10^{-2}}{0.0821 \times 298}\ \text{mol·L}^{-1} (= 4.50 \times 10^{-4}\ \text{mol·L}^{-1})$$



Step 2 Find the amount of solute molecules in the solution from $n_{\text{solute}} = c_{\text{solute}}V$.

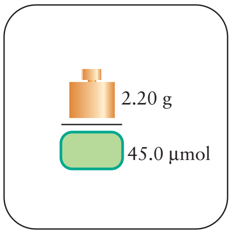
$$n(\text{PE}) = \left(\frac{1.10 \times 10^{-2}}{0.0821 \times 298}\ \text{mol·L}^{-1}\right) \times (0.100\ \text{L})$$

$$= \frac{1.10 \times 10^{-2} \times 0.100}{0.0821 \times 298}\ \text{mol}\ (= 4.50 \times 10^{-5}\ \text{mol})$$



Step 3 Find the molar mass from $M_{\text{solute}} = m_{\text{solute}}/n_{\text{solute}}$.

$$M(\text{PE}) = \frac{2.20\ \text{g}}{\dfrac{1.10 \times 10^{-2} \times 0.100}{0.0821 \times 298}\ \text{mol}} = 4.89 \times 10^{4}\ \text{g·mol}^{-1}$$



Evaluate We report this molar mass as 48.9 kg·mol^{-1}. As expected, the molar mass is very high.

Self-Test 9.15A The osmotic pressure of 3.0 g of polystyrene dissolved in enough benzene to produce 150. mL of solution was 1.21 kPa at 25°C. Calculate the average molar mass of the sample of polystyrene.

[***Answer:*** 41 kg·mol^{-1}]

Self-Test 9.15B The osmotic pressure of 1.50 g of polymethyl methacrylate dissolved in enough methylbenzene to produce 175 mL of solution was 2.11 kPa at 20°C. Calculate the average molar mass of the sample of polymethyl methacrylate.

In **reverse osmosis,** a pressure greater than the osmotic pressure is applied to the solution side of the semipermeable membrane. This application of pressure increases the rate at which solvent molecules leave the solution and thus reverses the flow of solvent, forcing it to flow from the solution to pure solvent. Reverse osmosis is used to remove salts from seawater to produce fresh water for drinking and irrigation. The water is almost literally squeezed out of the salt solution through the membrane. The technological challenge is to fabricate new membranes that are strong enough to withstand high pressures and do not easily become clogged. Commercial plants use cellulose acetate membranes at pressures as high as 70 atm.

Thinking point: Reverse osmosis is energy-intensive. Why?

> ***Osmosis is the flow of solvent through a semipermeable membrane into a solution; the osmotic pressure is proportional to the molar concentration of the solute. Osmometry is used to determine the molar masses of compounds with large molecules, such as polymers; reverse osmosis is used in water purification.***

BINARY LIQUID MIXTURES

The following three sections of this chapter examine how the vapor pressure varies with composition when both components of a mixture are volatile and how that information can be used to separate them by distillation. Distillation, which we first encountered in Section G, is used to separate the many compounds that make up petroleum and to purify alternative fuels such as ethanol and methanol.

9.18 The Vapor Pressure of a Binary Liquid Mixture

Consider an ideal binary mixture of the volatile liquids A and B. We could think of A as benzene, C_6H_6, and B as toluene (methylbenzene, $C_6H_5CH_3$), for example, because these two compounds have similar molecular structures and so form nearly ideal solutions. Because the mixture can be treated as ideal, each component has a vapor pressure given by Raoult's law:

$$P_A = x_A(l)P_A^* \qquad P_B = x_B(l)P_B^*$$

In these equations, $x_A(l)$ is the mole fraction of A in the liquid mixture and P_A^* is the vapor pressure of pure A; similarly, $x_B(l)$ is the mole fraction of B in the liquid and P_B^* is the vapor pressure of pure B. According to Dalton's law (Section 4.8), the total pressure of the vapor, P, is the sum of these two partial pressures (Fig. 9.35):

$$P = P_A + P_B = x_A(l)P_A^* + x_B(l)P_B^*$$

Therefore, we can calculate the vapor pressure of a mixture of two volatile liquids if we know their individual vapor pressures at the temperature of interest and their mole fractions in the mixture.

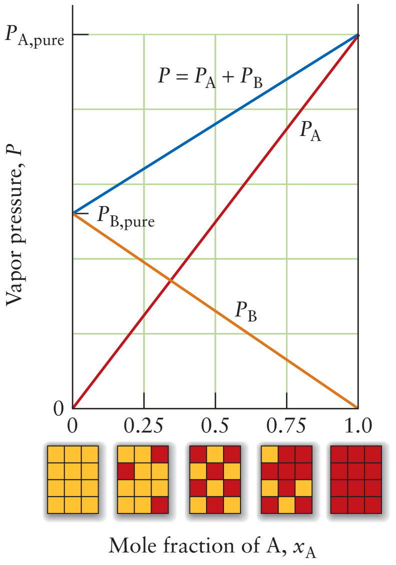


FIGURE 9.35 The vapor pressures of the two components of an ideal binary mixture obey Raoult's law. The total vapor pressure is the sum of the two partial vapor pressures (Dalton's law). The small rectangles below the graph represent the mole fraction of A (red squares).

EXAMPLE 9.11 Predicting the vapor pressure of a mixture of two liquids

What is the vapor pressure of each component at 25°C and the total vapor pressure of a mixture of benzene and toluene in which one-third of the molecules are benzene (so $x_{benzene}(l) = \frac{1}{3}$ and $x_{toluene}(l) = \frac{2}{3}$)? The vapor pressures of benzene and toluene at 25°C are 94.6 and 29.1 Torr, respectively.

Anticipate The vapor pressure of the mixture will lie between the values of the pure liquids, closer to the more abundant component, which in this case is toluene. So, we should expect a value between 29 and 95 Torr, but closer to 29 Torr.

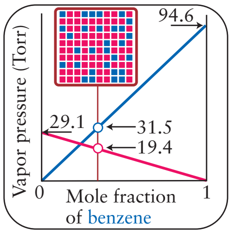
PLAN Use Raoult's law to calculate the vapor pressure of each component, then Dalton's law to calculate the total vapor pressure.

SOLVE

From Raoult's law in the form $P_A = x_A(l)P_A^*$ and $P_B = x_B(l)P_A^*$,

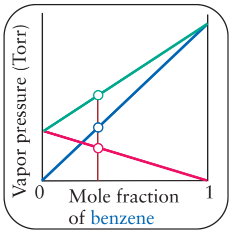
$$P_{benzene} = \tfrac{1}{3}(94.6\ \text{Torr}) = 31.5\ \text{Torr}$$

$$P_{toluene} = \tfrac{2}{3}(29.1\ \text{Torr}) = 19.4\ \text{Torr}$$



From Dalton's law, $P = P_A + P_B$,

$$P_{total} = 31.5 + 19.4\ \text{Torr} = 50.9\ \text{Torr}$$



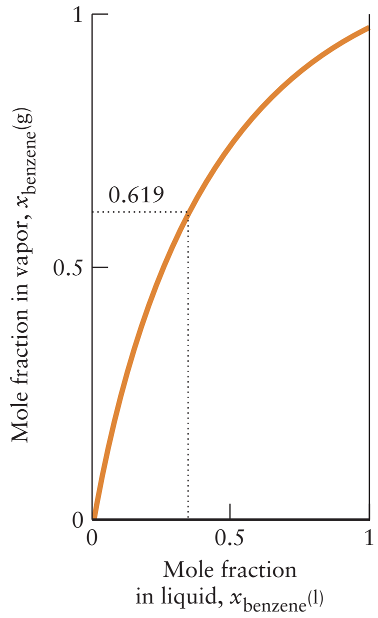


FIGURE 9.36 The composition of the vapor in equilibrium with a mixture of two volatile liquids (here, benzene and toluene) and its variation with the composition of the liquid. Note that the vapor is richer in the more volatile component (benzene) than the liquid mixture for each composition of the mixture. For instance, when the mole fraction of benzene is 0.333 in the liquid, in the vapor it is 0.619.

Evaluate As we expected, the vapor pressure of the mixture lies closer to that of toluene than that of benzene.

Self-Test 9.16A What is the total vapor pressure at 25°C of a mixture of 3.00 mol C_6H_6 (benzene) and 2.00 mol $C_6H_5CH_3$ (toluene)?

[***Answer:*** 68.4 Torr]

Self-Test 9.16B What is the total vapor pressure at 25°C of a mixture of equal masses of benzene and toluene?

The vapor of the mixture is richer than the liquid in the more volatile component (the component with the greater vapor pressure). Benzene, for instance, is more volatile than toluene, and so we can expect that the vapor in equilibrium with the liquid mixture will be richer in benzene than the liquid is. If we could express the composition of the vapor in terms of the composition of the liquid, we could confirm that the vapor is richer than the liquid in the more volatile component.

HOW DO WE DO THAT?

To express the composition of the vapor in equilibrium with the liquid phase of a binary liquid mixture, we first note that the definition of partial pressure ($P_A = x_A P$ for component A) and Dalton's law ($P = P_A + P_B$) allow us to express the composition of the vapor of a mixture of liquids A and B in terms of the partial pressures of the components:

$$x_A(\text{g}) = \frac{P_A}{P} = \frac{P_A}{P_A + P_B}$$

and likewise for $x_B(\text{g})$. We can express the vapor pressure of the components and the total vapor pressure in terms of the composition of the liquid (by using Raoult's law):

$$x_A(\text{g}) = \frac{x_A(\text{l})P_A{}^*}{x_A(\text{l})P_A{}^* + x_B(\text{l})P_B{}^*} = \frac{x_A(\text{l})P_A{}^*}{x_A(\text{l})P_A{}^* + (1 - x_A(\text{l}))P_B{}^*}$$

In the last term we have used $x_B = 1 - x_A$. This expression relates the composition of the vapor (in terms of the mole fraction of A in the vapor) in a binary mixture to the composition of the liquid (in terms of the mole fraction of A in the liquid). It is plotted for benzene and toluene in Fig. 9.36, and we see that $x_{\text{benzene}}(\text{g}) > x_{\text{benzene}}(\text{l})$, just as we anticipated.

EXAMPLE 9.12 **Predicting the composition of the vapor in equilibrium with a binary liquid mixture**

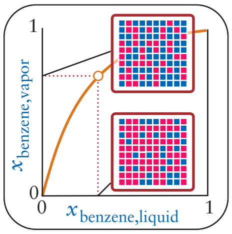
Find the mole fraction of benzene at 25°C in the vapor of a solution of benzene in toluene in which one-third of the molecules in the liquid are benzene. See Example 9.11 for data.

Anticipate Benzene is more volatile than toluene, so we should expect the vapor to be richer in benzene than the liquid is.

SOLVE

From $x_A(\text{g}) = x_A(\text{l})P_A{}^*/\{x_A(\text{l})P_A{}^* + (1 - x_B(\text{l}))P_B{}^*\}$,

$$x_{\text{benzene}}(\text{g}) = \frac{0.333 \times 94.6 \text{ Torr}}{0.333 \times 94.6 \text{ Torr} + (1 - 0.333) \times 29.1 \text{ Torr}}$$
$$= 0.619$$



Evaluate As expected, the vapor is richer in benzene than the liquid; in fact, the mole fraction of benzene in the vapor is nearly twice that in the liquid, as shown in Fig. 9.36.

Self-Test 9.17A (a) Determine the vapor pressure at 25°C of a solution of toluene in benzene in which the mole fraction of benzene is 0.900. (b) Calculate the mole fractions of benzene and toluene in the vapor.

[***Answer:*** (a) 88.0 Torr; (b) 0.967 and 0.033]

Self-Test 9.17B (a) Determine the vapor pressure at 25°C of a solution of benzene in toluene in which the mole fraction of benzene is 0.500. (b) Calculate the mole fractions of benzene and toluene in the vapor.

The vapor of an ideal mixture of two volatile liquids is richer than the liquid in the more volatile component. The contribution of each component to the total vapor pressure and its mole fraction in the vapor can be calculated by combining Raoult's law and Dalton's law.

9.19 Distillation

The normal boiling point of a binary liquid mixture is the temperature at which the total vapor pressure is equal to 1 atm. If we were to heat a sample of pure benzene at a constant pressure of 1 atm, it would boil at 80.1°C. Similarly, pure toluene boils at 110.6°C. Because, at a given temperature, the vapor pressure of a mixture of benzene and toluene is intermediate between that of toluene and benzene, the boiling point of the mixture will be intermediate between that of the two pure liquids. In Fig. 9.37, which is called a **temperature–composition diagram,** the lower curve shows how the normal boiling point of the mixture varies with the composition.

The upper curve in Fig. 9.37 shows the composition of the vapor in equilibrium with the liquid mixture at the boiling point: it has been constructed by the same kind of calculation as in Example 9.12. To find the composition of the vapor, we simply look along the **tie line,** the horizontal line at the boiling point, and see where it cuts through the upper curve. So, if we heat a liquid mixture with the composition given by the vertical line through A in Fig. 9.37 ($x_{benzene}(l) = 0.45$) at a constant pressure of 1 atm, the mixture boils at the temperature corresponding to point A. At this temperature, the composition of the vapor in equilibrium with the liquid is given by point B ($x_{benzene}(g) = 0.73$).

When a mixture of benzene and toluene molecules with $x_{benzene}(l) = 0.20$ begins to boil (point A in Fig. 9.38), the initial composition of the vapor formed is given by point B ($x_{benzene}(g) = 0.45$). If we were to cool the vapor until it condenses, the first drop of condensed vapor, the **distillate,** will have the composition of the vapor and is therefore richer in benzene than the original mixture; the liquid remaining in the pot is richer in toluene because some of the benzene has been lost. The separation is not very good: the distillate is still rich in toluene. However, if we take that drop of distillate and reheat it, it will boil at the temperature represented by point C, and the vapor above the boiling solution will have the composition D ($x_{benzene}(g) = 0.73$), as indicated by the tie line. Note that the distillate from this second stage of distillation is even richer in benzene than the distillate from the first stage. If we continued these steps of boiling, condensation, and boiling again, we would eventually obtain a very tiny amount of nearly pure benzene.

The process called **fractional distillation** uses a method of continuous redistillation to separate mixtures of liquids with similar boiling points, such as benzene and toluene: the mixture is heated and the rising vapor passes up through a tall column packed with material having a high surface area, such as glass beads (Fig. 9.39). The vapor begins to condense on the beads near the bottom of the column. However, as heating continues, the vapor condenses and vaporizes over and over as it rises; the liquid drips back into the boiling mixture. The vapor becomes richer in the component with the lower boiling point as it continues to rise through the column and passes out into the condenser. For example, in the case of benzene and toluene, the final distillate is nearly pure benzene, the more volatile of the components, whereas the liquid in the pot is nearly pure toluene.

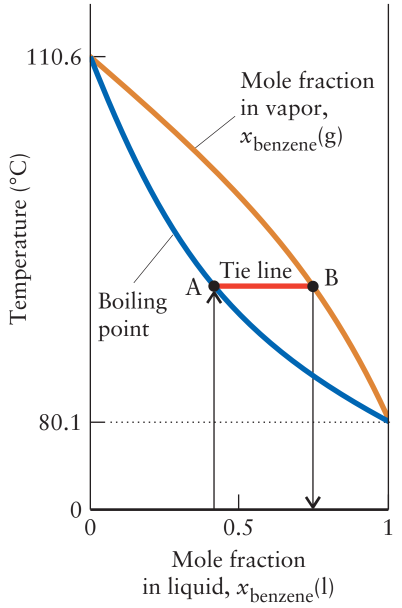


FIGURE 9.37 A temperature–composition diagram for benzene and toluene. The lower, blue curve shows the boiling point of the mixture as a function of composition. Tie lines connected to the upper, orange curve give the composition of the vapor in equilibrium with the liquid at each boiling point. Thus, point B shows the vapor composition for a mixture that boils at point A.

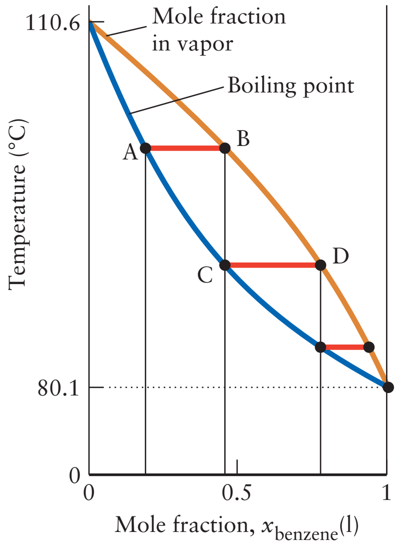

FIGURE 9.38 Some of the steps that represent fractional distillation of a mixture of two volatile liquids (benzene and toluene). The original mixture boils at A and its vapor has composition B. After condensation of the vapor, the resulting liquid boils at C and the vapor has composition D, and so on.

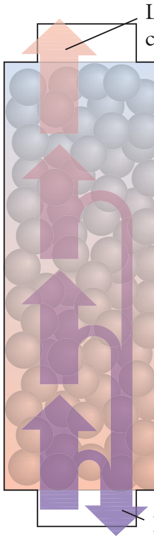

FIGURE 9.39 A schematic illustration of the process of fractional distillation. The temperature in the fractionating column decreases with height. The condensations and reboilings illustrated in Fig. 9.38 occur at increasing heights in the column. The less volatile component returns to the flask beneath the fractionating column, and the more volatile component escapes from the top, to be condensed and collected.

If the original sample consists of several volatile liquids, the component liquids appear in the distillate in succession in a series of **fractions,** or samples of the distillate that boil in specific temperature ranges. Giant fractionating columns are used in industry to separate complex mixtures such as crude petroleum (Fig. 9.40). We use the volatile fractions as natural gas (boiling below 0°C), gasoline (boiling in the range from 30°C to 200°C), and kerosene (from 180°C to 325°C). The less volatile fractions are used as diesel fuel (above 275°C). The residue that remains behind after distillation is asphalt, which is used for surfacing highways.

Volatile liquids can be separated by fractional distillation. Liquid and vapor are in equilibrium at each point in the fractionating column, but their compositions vary with height. As a result, the lowest-boiling-point component can be removed from the top of the column before the next-higher-boiling-point component distills.

9.20 Azeotropes

Most liquid mixtures are not ideal, and so their vapor pressures do not follow Raoult's law (Fig. 9.41). In these cases, the temperature–composition curves are determined experimentally by analyzing the composition of the vapor (often, after condensing it to a liquid). Deviations from Raoult's law can be correlated with the **enthalpy of mixing,** ΔH_{mix}, the enthalpy difference between the mixture and the pure components. The enthalpy of mixing of ethanol and benzene is positive—the mixing process is endothermic because the interactions between ethanol and benzene molecules are less favorable than between each type of molecule separately—and this mixture has a vapor pressure higher than that predicted by Raoult's law (a positive deviation). The enthalpy of mixing of acetone and chloroform is negative—the mixing process is exothermic because the interactions between acetone and chloroform molecules are stronger than those between molecules of chloroform or between molecules of acetone—and this mixture has a vapor pressure lower than that predicted by the law (a negative deviation).

The enthalpy of mixing is the same as the enthalpy of solution, ΔH_{sol}, but ΔH_{mix} is used more commonly for the mixing of two liquids.

FIGURE 9.40 The height of this tall fractionating column at an oil refinery helps to achieve a good separation of the components of petroleum.

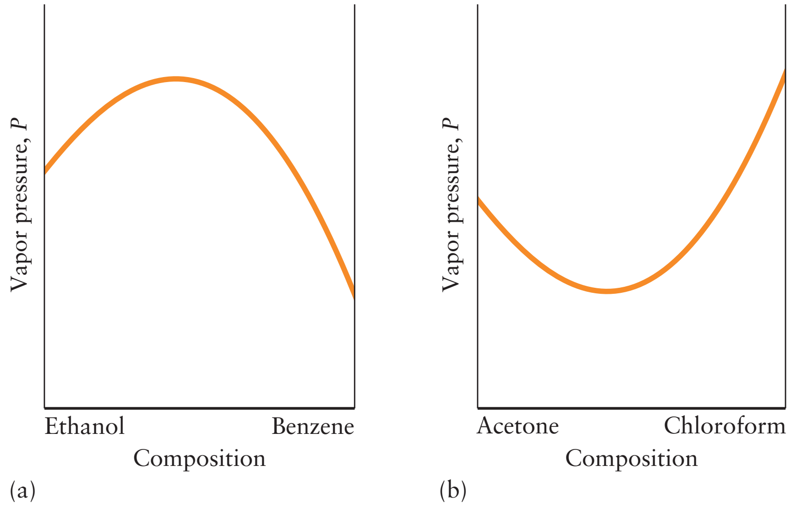

FIGURE 9.41 A graphical illustration of the variation in the vapor pressures of (a) a mixture of ethanol and benzene and (b) a mixture of acetone and chloroform. Note that the mixture in part (a) shows a vapor-pressure maximum and therefore displays a positive deviation from Raoult's law. The mixture in part (b) shows a minimum and hence displays a negative deviation from Raoult's law.

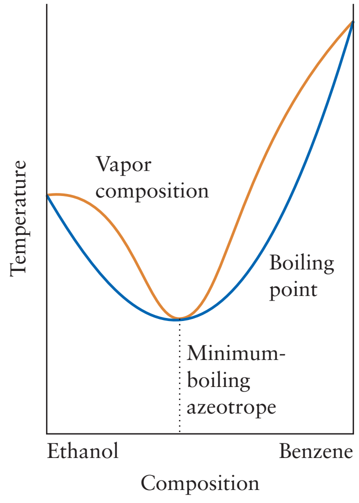

FIGURE 9.42 The temperature–composition diagram of a minimum-boiling azeotrope (such as ethanol and benzene). When this mixture is fractionally distilled, the (more volatile) azeotropic mixture is obtained as the initial distillate.

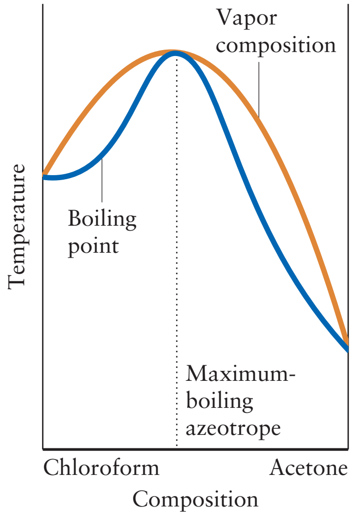

FIGURE 9.43 The temperature–composition diagram showing a maximum-boiling azeotrope (such as acetone and chloroform). When this mixture is fractionally distilled, the (less volatile) azeotropic mixture is left in the flask.

Some deviations from Raoult's law can make it impossible to separate liquids completely by distillation. The temperature–composition diagrams for mixtures of ethanol and benzene and of acetone and chloroform show why. A positive deviation from Raoult's law means that the attractive forces between solute and solvent are lower than those between the molecules of the pure components. As a result, the boiling point of the mixture is lower than that predicted by Raoult's law. For some pairs of components, the boiling point of the mixture is in fact lower than the boiling point of either constituent (Fig. 9.42). A mixture for which the lowest boiling temperature is below that of both pure components is called a **minimum-boiling azeotrope,** and the components cannot be separated by distillation: in a fractional distillation, a mixture with the azeotropic composition boils over first, not the more volatile pure liquid.

The name "azeotrope" is formed from Greek words meaning "boiling without change."

The opposite behavior is found for a mixture of acetone in chloroform (Fig. 9.43). This **maximum-boiling azeotrope** boils at a higher temperature than either constituent and is the last fraction to be collected, not the less volatile of the pure liquids. The reduction in vapor pressure results from the fact that, although neither molecule can form hydrogen bonds in the pure state, the partially positive hydrogen atom in the highly polar chloroform molecule can form a hydrogen bond to the partially negative oxygen atom in the acetone molecule.

Solutions in which intermolecular forces are stronger in the solution than in the pure components have negative deviations from Raoult's law; some form maximum-boiling azeotropes. Solutions in which intermolecular forces are weaker in the solution than in the pure components have positive deviations from Raoult's law; some form minimum-boiling azeotropes.

THE IMPACT ON BIOLOGY AND MATERIALS

The complexity and versatility of materials made by nature are the envy of scientists. We are only beginning to be able to create materials that have the strong yet porous structure of bone or the strength and flexibility of spider silk (Section 19.13). However, some materials are not strong: they are soft and flexible. These materials, some of which are described in the following two sections, are also important to industry and medicine and some are vital to life.

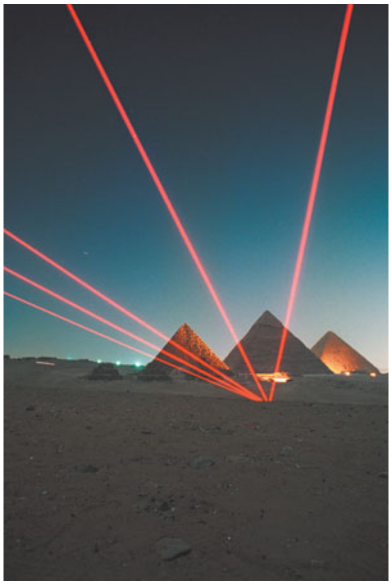

FIGURE 9.44 Laser beams are invisible. However, they can be traced when they pass through smoky or misty environments because the light scatters from the particles suspended in the air.

TABLE 9.9 The Classification of Colloids*

Dispersed phase	Dispersion medium	Technical name	Examples
solid	gas	aerosol	smoke
liquid	gas	aerosol	hairspray, mist, fog
solid	liquid	sol or gel	printing ink, paint
liquid	liquid	emulsion	milk, mayonnaise
gas	liquid	foam	fire-extinguisher foam
solid	solid	solid dispersion	ruby glass (Au in glass); some alloys
liquid	solid	solid emulsion	bituminous road paving; ice cream
gas	solid	solid foam	insulating foam

*Based on R. J. Hunter, *Foundations of Colloid Science*, Vol. 1 (Oxford: Oxford University Press, 1987).

9.21 Colloids

A **colloid** is a dispersion of large particles (from 1 nm to 1 μm in diameter) in a solvent. Colloidal particles are much larger than most molecules but are too small to be seen with an optical microscope. As a result, colloids have properties between those of a solution and those of a heterogeneous mixture. The small particles give the colloid a homogeneous appearance but are large enough to scatter light. The light scattering explains why milk is white, not transparent, and why searchlight and laser beams are more visible in fog, smoke, and clouds than in clear, dry air (Fig. 9.44). Many foods are colloids, as are clay particles, smoke, and the fluids in living cells. Some self-assembling materials are colloids that form orderly structures spontaneously (see Box 15. 2).

Colloids are classified according to the phases of their components (Table 9.9). A colloid that is a suspension of solids in a liquid is called a **sol**, and a suspension of one liquid in another is called an **emulsion.** For example, muddy water is a sol in which tiny flakes of clay are dispersed in water; mayonnaise is an emulsion in which small droplets of water are suspended in vegetable oil. **Foam** is a suspension of a gas in a liquid or solid. Foam rubber, Styrofoam, soapsuds, and aerogels (insulating ceramic foams that have densities nearly as low as that of air) are foams. Zeolites (Section 14.15) are a type of solid foam in which the openings in the solid are comparable in size to molecules.

A **solid emulsion** is a suspension of a liquid or solid phase in a solid. For example, opals are solid emulsions formed when partly hydrated silica fills the interstices between close-packed microspheres of silica aggregates. Gelatin desserts are a type of solid emulsion called a **gel**, which is soft but holds its shape. Photographic emulsions are gels that also contain solid colloidal particles of light-sensitive materials such as silver bromide. Many liquid crystalline arrays can be considered colloids. Cell membranes form a two-dimensional colloidal structure (Fig. 9.45).

Aqueous colloids can be classified as hydrophilic or hydrophobic, depending on the strength of the molecular interactions between the suspended substance and water. Suspensions of fat in water (such as milk) and water in fat (such as mayonnaise and hand lotions) are hydrophobic colloids, because fat molecules have little attraction for water molecules. Gels and puddings are examples of hydrophilic colloids. The macromolecules of the proteins in gelatin and the starch in pudding have many hydrophilic groups that attract water. The giant protein molecules in gelatin uncoil in hot water, and their numerous polar groups form hydrogen bonds with the water. When the mixture cools, the protein chains link together again, but now they have entwined to form a three-dimensional web that encloses many water molecules, as well as molecules of sugar, dye, and flavoring agents. The result is a gel: an open network of protein chains that holds the water in a flexible solid structure.

Clusters of metal atoms can form colloidal suspensions. Colloidal clusters of copper, silver, and gold in glass are responsible for some of the vivid colors of stained glass in medieval cathedrals (Fig. 9.46). Even aqueous suspensions of metal clusters are known (Fig. 9.47).

FIGURE 9.46 The colors of stained glass are created by incorporating colloidal particles of selected materials into molten glass.

Many precipitates, such as $Fe(OH)_3$, form initially as colloidal suspensions. The tiny particles are kept from settling out by **Brownian motion,** the motion of small particles resulting from constant bombardment by solvent molecules. The sol is further stabilized by the adsorption of ions on the surfaces of the particles. The ions attract a layer of water molecules that prevents the particles from adhering to one another.

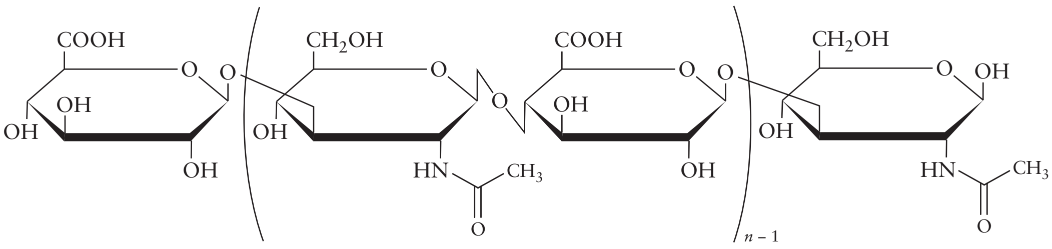
FIGURE 9.47 The stability of colloids is illustrated by this violet liquid, which is a colloid of metallic gold that has survived since it was prepared by Michael Faraday in 1857.

Colloids are suspensions of particles typically too small to be seen with a microscope but large enough to scatter light.

9.22 Bio-based and Biomimetic Materials

Bio-based materials are materials that are taken from or made from natural materials in living things. Examples include packing pellets made from corn and soybeans, polylactic acid (a polymer used to make plastic packaging), and various kinds of pharmaceuticals.

One example of a colloidal bio-based pharmaceutical material is hyaluronic acid (**5**). This compound occurs naturally in the body, where it is a major component of the fluid that lubricates joints and plays an important role in the repair of tissues, especially in the skin. Because the molecules of hyaluronic acid contain many —OH groups, it can form hydrogen bonds to water and form a colloid. As a result, as it moves through the body large numbers of water molecules move with it.



5 Hyaluronic acid

This property makes it useful in regions of the body that require lubrication, such as joints, and in the healing of wounds and connective tissue (Fig. 9.48). Hyaluronic acid is widely used in sports medicine to heal joint injuries by reducing inflammation. Because hyaluronic acid is easily metabolized in the stomach, it must be injected into the region where it is needed.

Biomimetic materials are materials that are modeled after naturally occurring materials. Gels or flexible polymers (Chapter 19) modeled after natural membranes and tissues are biomimetic materials with remarkable properties. Some can be made to crawl on their own like tiny nanometer worms, others pulsate to an internally generated rhythm, and still others respond in seemingly lifelike ways to stimuli.

Controlled-release drug delivery systems can be made from liquid crystals (Section 5.15). Surfactant compounds called *phospholipids* are found in fats and form the membranes of living cells. These molecules are liquid crystals similar to detergent molecules (Section 9.9). The membranes of living cells are double layers of phospholipid molecules that line up with their hydrocarbon tails pointing into the membrane and their polar head groups forming the membrane surface. This structure separates the contents of the cell from the intercellular fluid. It is possible to coax phospholipids to form artificial membranes that close up to form tiny bags, called *liposomes*, which are much smaller than living cells (see Fig. 9.45). If the liposomes are formed in a solution containing a drug, some drug molecules become encapsulated. This behavior has led to the study of liposomes as a way of delivering drugs into different organs and regions of the body (Box 9.1).

FIGURE 9.48 Hyaluronic acid has the consistency of a soft gel. It absorbs water easily and bonds with the proteins in the skin, making it useful in the repair of wounds and joint injuries.

Biomimetic materials are modeled after naturally occurring biological materials.

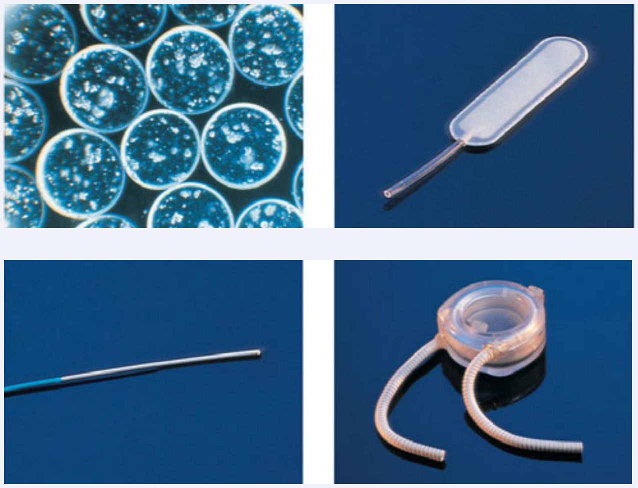
BOX 9.1 FRONTIERS OF CHEMISTRY: DRUG DELIVERY

The administration of drugs to ease disease and chronic, severe pain or to provide benefits such as hormone replacement therapy is difficult because drugs taken orally may lose much of their potency in the harsh conditions of the digestive system. In addition, they are distributed throughout the entire body, not just where they are needed, and side effects can be significant. Recently, however, techniques have been developed to deliver drugs gradually over time, to the exact location in the body where they are needed, and even at the time when they are needed.

Transdermal patches are applied to the skin. The drug is mixed with the adhesive for the patch, and so it lies next to the skin. The skin can readily absorb many chemicals and so can absorb drugs such as nitroglycerin (for heart disease), morphine derivatives (for constant, severe pain), estrogen (for hormone replacement therapy), or nicotine (for easing symptoms that result when a patient stops smoking).

Implants provide a means of delivering drugs over a longer period of time at a controlled rate inside the body. Subcutaneous (under the skin) implants are used to provide appropriate doses of psychoactive medications, birth-control drugs, painkillers, and other medications that must be administered frequently. The implants last for as long as a month and can be easily replaced or renewed. When the location of the drug release is critical, implants can be placed deeper into the body. For example, implants can be introduced into the brain or spinal column to provide effective relief from pain or to protect neurons from degeneration. The implant is contained inside a cylinder of porous foam through which the drug is released. Some implants contain living animal cells that have been engineered to produce natural hormones or painkillers that are released to the body as they are produced. In other types of implants, membranes allow a gradual release of the drug.

Controlled-release drug delivery systems mimic nature. Molecules called lipids are found in fats and also form the membranes of living cells. A lipid molecule is similar in structure to the surfactant molecules in detergents: it has a polar head and a nonpolar hydrocarbon tail. Some lipids assemble themselves spontaneously into liquid crystal structures in water (Section 9.22); in these structures, sheets consisting of rows of molecules are lined up next to one another. The sheets can be coaxed into forming liposomes (see Fig. 9.45). Liposomes are similar to micelles but are formed from a double layer of molecules, with polar heads forming each surface, like the membrane of a living cell. When a drug is present in the aqueous solution in which liposomes are being formed, some of the drug is encapsulated inside each liposome, which becomes a tiny container for the drug. The liposomes can then be injected into the body, where they stick only to certain types of cells—cancer cells, for instance. Compared with oral or intravenous medicine, a smaller dosage is required and side effects are greatly reduced.



Examples of implants used to insert living cells into the body. The cells continually produce enzymes, hormones, or painkillers needed by the body. Often a long, thin plastic tail is attached as a tether to allow easy retrieval of the implant.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Use the Clausius–Clapeyron equation to estimate the vapor pressure or boiling point of a liquid (Examples 9.1 and 9.2).

❑ 2 Interpret a one-component phase diagram (Example 9.3).

❑ 3 Predict relative solubilities from molecular polarity (Section 9.9).

❑ 4 Use Henry's law to calculate the solubility of a gas (Example 9.4).

❑ 5 Interpret enthalpies of solution in terms of lattice enthalpies and enthalpies of hydration (Section 9.12).

❑ 6 Calculate the molality of a solute (Example 9.5).

❑ 7 Convert between molality and mole fraction or molarity (Toolbox 9.1 and Examples 9.6 and 9.7).

❑ 8 Calculate the vapor pressure of a solvent in a solution by using Raoult's law (Example 9.8).

❑ 9 Determine molar mass cryoscopically (Toolbox 9.2 and Example 9.9).

❑ 10 Use osmometry to find the molar mass of a solute (Toolbox 9.2 and Example 9.10).

❑ 11 Calculate the vapor pressure and vapor composition for a solution of two liquids (Examples 9.11 and 9.12).

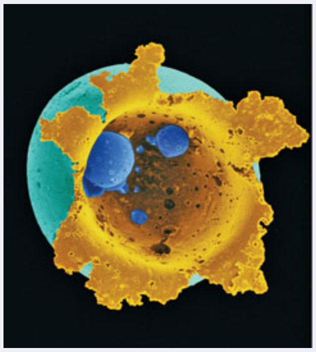
❑ 12 Interpret a two-component phase diagram and discuss fractional distillation (Sections 9.18, 9.19, and 9.20).

❑ 13 Identify colloids and explain their properties (Section 9.21).

❑ 14 Describe the structure of cell membranes (Section 9.22).

This implant containing live hamster cells was inserted into the spinal column of a patient for 17 weeks. After removal, the cells were still alive and secreting the hormone required to keep the patient healthy.

Nanotechnology has led to very efficient versions of liposomes. Tiny hollow spheres only nanometers in diameter hold even tinier capsules of medicine. The spheres are made of silica covered with gold nanoparticles and when they are coated with antibodies they attach to tumor cells. The spheres are sensitive to light of specific wavelengths and when the light is applied, they either heat up and destroy the tumor, or burst, releasing the drugs within the capsules directly into the tumor.



An electron microscope image of a drug capsule as it bursts open, revealing the tiny microcapsules inside. The image has been digitally colored.

Smart gels (see Box 15.2) are being investigated for drug delivery in situations in which the drug dosage must be modified according to conditions in the body. For example, the amount of insulin that a nondiabetic person needs is delivered by the body according to the level of blood sugar. However, a diabetic person must take insulin at specified times of the day and the same amount each time. If the blood sugar is already low, a hypoglycemic reaction, and possibly coma, can result. An insulin delivery system that would be responsive to blood sugar levels and provide the correct dosage when it is needed is now being investigated. The system makes use of a smart gel in which molecules of insulin have been trapped. The gel incorporates into its structure molecules of phenylboronic acid, to which glucose (blood sugar) molecules are attracted. If the blood sugar is high, more and more glucose molecules stick to the gel and cause it to swell. When the level of glucose rises above a certain concentration, the gel swells so much that it becomes porous, releasing insulin into the blood.

? HOW MIGHT YOU CONTRIBUTE?

Both basic and applied research are needed for effective drug delivery systems. Basic research on the self-assembly of molecules may allow more innovative solutions in the future. Applied research may have more immediate benefits. For example, the optimal drug delivery system must be designed for each specific drug. Coatings for implants or nanospheres that are nontoxic and are similar in nature to body tissues need to be developed. Both the length of time during which a drug delivery system can remain active inside the body and the stability of the system need to be increased.

EXERCISES

Phases and Phase Transitions

9.1 Suppose you were to collect 1.0 L of air by passing it slowly through water at 20.°C and into a container. Estimate the mass of water vapor in the collected air, assuming that the air is saturated with it.

9.2 A bottle of mercury at 25°C was left unstoppered in a chemical supply room measuring 3.0 m by 3.0 m by 2.5 m. What mass of mercury vapor would be present if the air became saturated with it? The vapor pressure of mercury at 25°C is 0.227 Pa.

9.3 Use the vapor-pressure curve in Fig. 9.3 to estimate the boiling point of water when the atmospheric pressure is (a) 60. kPa; (b) 160. kPa.

9.4 Use the vapor-pressure curve in Fig. 9.3 to estimate the boiling point of benzene when the atmospheric pressure is (a) 50. kPa; (b) 80. kPa.

9.5 The vapor pressure of boron trichloride at −28°C is 17.0 kPa and its enthalpy of vaporization is 23.77 $kJ \cdot mol^{-1}$. What is the boiling point of boron trichloride?

9.6 The vapor pressure of dimethyl ether at –58°C is 18.1 kPa and its enthalpy of vaporization is 21.51 $kJ \cdot mol^{-1}$. What is the boiling point of dimethyl ether?

9.7 Arsine, AsH_3, is a highly toxic compound used in the electronics industry for the production of semiconductors. Its vapor pressure is 35 Torr at −111.95°C and 253 Torr at −83.6°C.

Using these data, calculate (a) the standard enthalpy of vaporization; (b) the standard entropy of vaporization; (c) the standard Gibbs free energy of vaporization; (d) the normal boiling point of arsine.

9.8 The vapor pressure of chlorine dioxide, ClO_2, is 155 Torr at −22.75°C and 485 Torr at 0.00°C. Calculate (a) the standard enthalpy of vaporization; (b) the standard entropy of vaporization; (c) the standard Gibbs free energy of vaporization; (d) the normal boiling point of ClO_2.

9.9 The normal boiling point of iodomethane, CH_3I, is 42.43°C, and its vapor pressure at 0.00°C is 140. Torr. Calculate (a) the standard enthalpy of vaporization of iodomethane; (b) the standard entropy of vaporization of iodomethane; (c) the vapor pressure of iodomethane at 25.0°C.

9.10 The normal boiling point of trimethylphosphine, $P(CH_3)_3$, is 38.4°C, and its vapor pressure at −45.21°C is 13 Torr. Calculate (a) the standard enthalpy of vaporization of trimethylphosphine; (b) the standard entropy of vaporization of trimethylphosphine; (c) the vapor pressure of trimethylphosphine at 15.0°C.

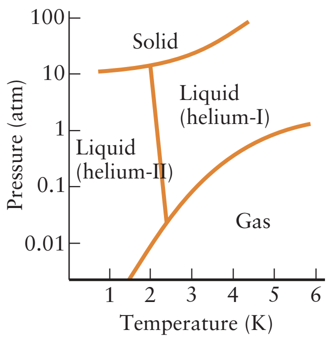
9.11 Use data from Table 7.3 to calculate the vapor pressure of methanol at 25.0°C.

9.12 Use data from Table 7.3 to calculate the vapor pressure of ammonia at 235 K.

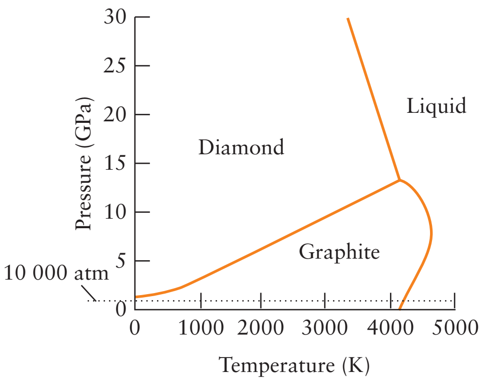
9.13 Use Fig. 9.6 to predict the state of a sample of water under the following conditions: (a) 1 atm, 200.°C; (b) 100. atm, 50.0.°C; (c) 3 Torr, 10.0°C.

9.14 Use Fig. 9.7 to predict the state of a sample of CO_2 under the following conditions: (a) 6 atm, –80.°C; (b) 1 atm, −56°C; (c) 80. atm, 25°C; (c) 5.1 atm, −56°C.

9.15 The phase diagram for helium is shown here. (a) What is the maximum temperature at which superfluid helium-II can exist? (b) What is the minimum pressure at which solid helium can exist? (c) What is the normal boiling point of helium-I? (d) Can solid helium sublime?



9.16 The phase diagram for carbon, shown here, indicates the extreme conditions that are needed to form diamonds from graphite. (a) At 2000 K, what is the minimum pressure needed before graphite changes into diamond? (b) What is the minimum temperature at which liquid carbon can exist at pressures below 10 000 atm? (c) At what pressure does graphite melt at 3000 K? (d) Are diamonds stable under normal conditions? If not, why is it that people can wear them without having to keep them under high pressure?



9.17 Use the phase diagram for helium in Exercise 9.15 (a) to describe the phases in equilibrium at each of helium's two triple points; (b) to decide which liquid phase is the more dense, helium-I or helium-II.

9.18 Use the phase diagram for carbon in Exercise 9.16 (a) to describe the phase transitions that carbon would undergo if compressed at a constant temperature of 2000 K from 100 atm to 1×10^6 atm; (b) to rank the diamond, graphite, and liquid phases of carbon in order of increasing density.

9.19 Use the phase diagram for carbon dioxide (Fig. 9.7) to predict what would happen to a sample of carbon dioxide gas at –50°C and 1 atm if its pressure were suddenly increased to 73 atm at constant temperature. What would be the final physical state of the carbon dioxide?

9.20 A new substance developed in a laboratory has the following properties: normal melting point, 83.7°C; normal boiling point, 177°C; triple point, 200. Torr and 38.6°C. (a) Sketch the approximate phase diagram and label the solid, liquid, and gaseous phases and the solid–liquid, liquid–gas, and solid–gas phase boundaries. (b) Sketch an approximate heating curve for a sample at constant pressure, beginning at 500. Torr and 25°C and ending at 200.°C.

Solubility

9.21 Which would be the better solvent, water or benzene, for each of the following substances: (a) KCl; (b) CCl_4; (c) CH_3COOH?

9.22 Which would be the better solvent, water or tetrachloromethane, for each of the following substances: (a) NH_3; (b) HNO_3; (c) N_2?

9.23 The following groups are found in some organic molecules. Which are hydrophilic and which are hydrophobic: (a) $—NH_2$; (b) $—CH_3$; (c) —Br; (d) —COOH?

9.24 The following groups are found in some organic molecules. Which are hydrophilic and which are hydrophobic: (a) —OH; (b) $—CH_2CH_3$; (c) $—CONH_2$; (d) —Cl?

9.25 State the molar solubility in water of (a) O_2 at 50. kPa; (b) CO_2 at 500. Torr; (c) CO_2 at 0.10 atm. The temperature in each case is 20.°C, and the pressures are partial pressures of the gases. Use the information in Table 9.5.

9.26 Calculate the solubility in water (in milligrams per liter) of (a) air at 0.80 atm; (b) He at 0.80 atm; (c) He at 36 kPa. The temperature is 20.°C in each case, and the pressures are partial pressures of the gases. Use the information in Table 9.5.

9.27 The minimum mass concentration of oxygen required for fish life is 4 mg·L^{-1}. (a) Assume the density of lake water to be 1.00 g·mL^{-1}, and express this concentration in parts per million (which is equivalent to milligrams of O_2 per kilogram of water, mg·kg^{-1}. (b) What is the minimum partial pressure of O_2 that would supply the minimum mass concentration of oxygen in water to support fish life at 20.°C? (c) What is the minimum atmospheric pressure that would give this partial pressure, assuming that oxygen exerts about 21% of the atmospheric pressure? See Table 9.5.

9.28 The volume of blood in the body of a certain deep-sea diver is about 6.00 L. Blood cells make up about 55% of the blood volume, and the remaining 45% is the aqueous solution called plasma. What is the maximum volume of nitrogen measured at 1.00 atm and 37°C that could dissolve in the diver's blood plasma at a depth of 93 m, where the pressure is 10.0 atm? (This is the volume that could come out of solution suddenly, causing the painful and dangerous condition called the bends, if the diver were to ascend too quickly.) Assume that Henry's constant for nitrogen at 37°C (body temperature) is 5.8×10^{-4} mol·L^{-1}·atm^{-1}.

9.29 The carbon dioxide gas dissolved in a sample of water in a partly filled, sealed container has reached equilibrium with its partial pressure in the air above the solution. Explain what happens to the solubility of the CO_2 if (a) the partial pressure of the CO_2 gas is doubled by the addition of more CO_2; (b) the total pressure of the gas above the liquid is doubled by the addition of nitrogen.

9.30 Explain what happens to the solubility of the CO_2 in Exercise 9.29 if (a) the partial pressure of CO_2(g) is increased by compressing the gas to a third of its original volume; (b) the temperature is raised.

9.31 A soft drink is made by dissolving CO_2 gas at 3.60 atm in a flavored solution and sealing the solution in aluminum cans at 20.°C. What amount of CO_2 is contained in a 420-mL can of the soft drink? At 20.°C the Henry's law constant for CO_2 is 2.3×10^{-2} mol·L^{-1}·atm^{-1}.

9.32 A soft drink is made by dissolving CO_2 gas at 4.00 atm in a flavored solution and sealing the solution in aluminum cans at 20.°C. What amount (in moles) of CO_2 is contained in a 360.-mL can of the soft drink? At 20.°C the Henry's law constant for CO_2 is 2.3×10^{-2} mol·L^{-1}·atm^{-1}.

9.33 Lithium sulfate dissolves exothermically in water. (a) Is the enthalpy of solution for Li_2SO_4 positive or negative? (b) Write the chemical equation for the dissolving process. (c) Which is larger for lithium sulfate, the lattice enthalpy or the enthalpy of hydration?

9.34 The enthalpy of solution of ammonium nitrate in water is positive. (a) Does NH_4NO_3 dissolve endothermically or exothermically? (b) Write the chemical equation for the dissolving process. (c) Which is larger for NH_4NO_3, the lattice enthalpy or the enthalpy of hydration?

9.35 Calculate the heat evolved or absorbed when 10.0 g of (a) NaCl; (b) NaI; (c) $AlCl_3$; (d) NH_4NO_3 is dissolved in 100. g of water. Assume that the enthalpies of solution in Table 9.6 are applicable and that the specific heat capacity of the solution is 4.18 J·K^{-1}·g^{-1}.

9.36 Determine the temperature change when 10.0 g of (a) KCl; (b) $MgBr_2$; (c) KNO_3; (d) NaOH is dissolved in 100. g of water. Assume that the specific heat capacity of the solution is 4.18 J·K^{-1}·g^{-1} and that the enthalpies of solution in Table 9.6 are applicable.

Colligative Properties

9.37 Calculate (a) the molality of sodium chloride in a solution prepared by dissolving 25.0 g of NaCl in 500.0 g of water; (b) the mass (in grams) of NaOH that must be mixed with 345 g of water to prepare 0.18 m NaOH(aq); (c) the molality of urea, $CO(NH_2)_2$, in a solution prepared by dissolving 0.978 g of urea in 285 mL of water.

9.38 Calculate (a) the molality of KOH in a solution prepared from 4.25 g of KOH and 55.0 g of water; (b) the mass (in grams) of ethylene glycol, HOC_2H_4OH, that should be added to 0.85 kg of water to prepare 0.35 m HOC_2H_4OH(aq); (c) the molality of an aqueous 4.12% by mass HCl solution.

9.39 A 5.00% by mass K_3PO_4 aqueous solution has a density of 1.043 g·cm^{-3}. Determine (a) the molality; (b) the molarity of potassium phosphate in the solution.

9.40 Calculate the concentrations of each of the following solutions: (a) the molality of 13.63 g of sucrose, $C_{12}H_{22}O_{11}$, dissolved in 612 mL of water; (b) the molality of CsCl in a 10.00% by mass aqueous solution; (c) the molality of acetone in an aqueous solution with a mole fraction for acetone of 0.197.

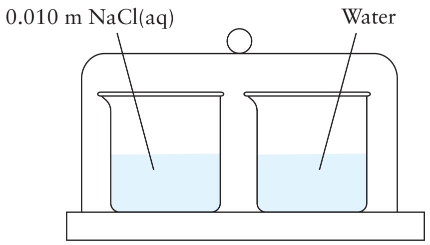
9.41 Calculate the concentrations of each of the following solutions: (a) the molality of chloride ions in an aqueous solution of magnesium chloride in which x_{MgCl_2} is 0.0120; (b) the molality of 6.75 g of sodium hydroxide dissolved in 325 g of water; (c) the molality of 15.00 M HCl(aq) with a density of 1.0745 g·cm^{-3}.

9.42 Calculate the concentrations of each of the following solutions: (a) the molality of chloride ions in an aqueous solution of iron(III) chloride for which x_{FeCl_3} is 0.0312; (b) the molality of hydroxide ions in a solution prepared from 3.24 g of barium hydroxide dissolved in 258 g of water.; (c) the molality of 12.00 M NH_3(aq) with a density of 0.9519 g·cm^{-3}.

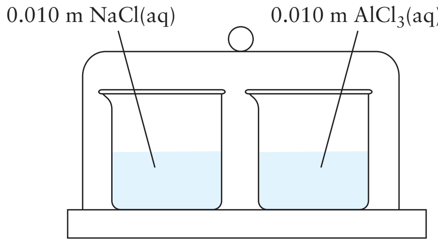
9.43 (a) Calculate the mass of $CaCl_2{\cdot}6H_2O$ needed to prepare 0.125 m $CaCl_2$(aq) by using 500. g of water. (b) What mass of $NiSO_4{\cdot}6H_2O$ must be dissolved in 500. g of water to produce 0.22 m $NiSO_4$(aq)?

9.44 A 10.0% by mass H_2SO_4(aq) solution has a density of 1.07 g·cm^{-3}. (a) How many milliliters of solution contain 8.37 g of H_2SO_4? (b) What is the molality of H_2SO_4 in solution? (c) What mass (in grams) of H_2SO_4 is in 250. mL of solution?

9.45 Two beakers, one containing 0.010 m NaCl (aq) and the other containing pure water, are placed inside a bell jar and sealed. The beakers are left until the water vapor has come to equilibrium with any liquid in the container. The levels of the liquid in each beaker at the beginning of the experiment are the same, as pictured below. Draw the levels of the liquid in each beaker after equilibrium has been reached. Explain your reasoning.



9.46 Two beakers, one containing 0.010 m NaCl(aq) and the other containing 0.010 m $AlCl_3$(aq), are placed inside a bell jar and sealed. The beakers are left until the water vapor has come to equilibrium with any liquid in the container. The levels of the liquid in each beaker at the beginning of the experiment are the same, as pictured below. Draw the levels of the liquid in each beaker after equilibrium has been reached. Explain your reasoning.



9.47 Calculate the vapor pressure of the solvent in each of the following solutions. Use Table 9.3 to find the vapor pressure of water in (a) an aqueous solution at 100.°C in which the mole fraction of sucrose is 0.100; (b) an aqueous solution at 100.°C in which the molality of sucrose is 0.100 mol·kg^{-1}.

9.48 What is the vapor pressure of the solvent in each of the following solutions: (a) the mole fraction of glucose is 0.050 in an aqueous solution at 80.°C; (b) an aqueous solution at 25°C is 0.10 m urea, $CO(NH_2)_2$, a nonelectrolyte? Use the data in Table 9.3 for the vapor pressure of water at various temperatures.

9.49 Benzene, C_6H_6, has a vapor pressure of 94.6 Torr at 25°C. A nonvolatile compound was added to 0.300 mol C_6H_6(l) at 25°C and the vapor pressure of the benzene in the solution decreased to 75.0 Torr. What amount (in moles) of solute molecules was added to the benzene?

9.50 Benzene has a vapor pressure of 100.0 Torr at 26°C. A nonvolatile compound was added to 0.300 mol C_6H_6(l) at 26°C and the vapor pressure of the benzene in the solution decreased to 60.0 Torr. What amount (in moles) of solute molecules were added to the benzene?

9.51 When 8.05 g of an unknown compound X was dissolved in 100. g of benzene, the vapor pressure of the benzene decreased from 100.0 Torr to 94.8 Torr at 26°C. What is (a) the mole fraction and (b) the molar mass of X?

9.52 The normal boiling point of ethanol is 78.4°C. When 9.15 g of a soluble nonelectrolyte was dissolved in 100. g of ethanol, the vapor pressure of the solution at that temperature was 7.40×10^2 Torr. (a) What are the mole fractions of ethanol and solute? (b) What is the molar mass of the solute?

9.53 (a) What is the normal boiling point of an aqueous solution that has a vapor pressure of 751 Torr at 100.°C? (b) Determine the normal boiling point of a benzene solution that has a vapor pressure of 740. Torr at 80.1°C, the normal boiling point of pure benzene.

9.54 (a) What is the normal boiling point of an aqueous solution that has a freezing point of –1.04°C? (b) The freezing point of a benzene solution is 2.0°C. The normal freezing point of benzene is 5.5°C. What is the expected normal boiling point of the solution? The normal boiling point of benzene is 80.1°C.

9.55 A 1.14-g sample of a molecular substance dissolved in 100. g of camphor freezes at 176.9°C. What is the molar mass of the substance?

9.56 When 1.32 g of a nonpolar solute was dissolved in 50.0 g of phenol, the latter's freezing point was lowered by 1.454°C. Calculate the molar mass of the solute.

9.57 A 1.00% by mass NaCl(aq) solution has a freezing point of –0.593°C. (a) Estimate the van 't Hoff *i* factor from the data. (b) Determine the total molality of all solute species. (c) Calculate the percentage dissociation of NaCl in this solution. (The molality calculated from the freezing-point depression is the sum of the molalities of the undissociated ion pairs, the Na^+ ions, and the Cl^- ions.)

9.58 A 1.00% by mass $MgSO_4$(aq) solution has a freezing point of –0.192°C. (a) Estimate the van 't Hoff *i* factor from the data. (b) Determine the total molality of all solute species. (c) Calculate the percentage dissociation of $MgSO_4$ in this solution.

9.59 Two unknown molecular compounds were being studied. A solution containing 5.00 g of compound A in 100. g of water froze at a lower temperature than a solution containing 5.00 g of compound B in 100. g of water. Which compound has the greater molar mass? Explain how you decided your answer.

9.60 Two unknown compounds were being studied. Compound C is molecular and compound D is known to ionize completely in dilute aqueous solutions. A solution containing 0.30 g of compound C in 100. g of water froze at the same temperature as a solution containing 0.30 g of compound D in 100. g of water. Which compound has the greater molar mass? Explain how you decided your answer.

9.61 Determine the freezing point of a 0.10 mol·kg^{-1} aqueous solution of a weak electrolyte that is 7.5% dissociated into two ions.

9.62 A 0.124 m CCl_3COOH(aq) solution has a freezing point of −0.423°C. What is the percentage deprotonation of the acid?

9.63 What is the osmotic pressure at 20.°C of (a) 0.010 M $C_{12}H_{22}O_{11}$(aq); (b) 1.0 M HCl(aq); (c) 0.010 M $CaCl_2$(aq)? Assume complete dissociation of the $CaCl_2$.

9.64 Which of the following solutions has the highest osmotic pressure at 50.°C: (a) 0.10 M KCl(aq); (b) 0.60 M $CO(NH_2)_2$(aq); (c) 0.30 M K_2SO_4(aq)? Justify your answer by calculating the osmotic pressure of each solution.

9.65 An aqueous solution of the sugar mannitol ($C_6H_{12}O_6$) with a concentration of 180 mg·mL^{-1} is commonly used in veterinary medicine as an osmotic diuretic, which helps to remove water from living cells by osmosis. (a) What is the molarity of mannitol in the solution? (b) What is the osmotic pressure of the solution at 25°C?

9.66 A dextrose/saline aqueous solution doctors commonly use to replace fluids in the body contains 1.75 g·L^{-1} NaCl and 40.0 g·L^{-1} dextrose ($C_6H_{12}O_6$). (a) What is the molarity of all solutes in this solution? (b) What is the osmotic pressure of the solution at 25°C? Assume total dissociation of the NaCl.

9.67 A 0.40-g sample of a polypeptide dissolved in 1.0 L of an aqueous solution at 27°C gave rise to an osmotic pressure of 3.74 Torr. What is the molar mass of the polypeptide?

9.68 When 0.10 g of insulin is dissolved in 0.200 L of water, the osmotic pressure is 2.30 Torr at 20.°C. What is the molar mass of insulin?

9.69 A 0.20-g sample of a polymer, dissolved in 0.100 L of toluene, has an osmotic pressure of 6.3 Torr at 20.°C. What is the molar mass of the polymer?

9.70 A solution prepared by adding 0.50 g of a polymer to 0.200 L of toluene (methylbenzene, a common solvent) showed an osmotic pressure of 0.582 Torr at 20.°C. What is the molar mass of the polymer?

9.71 Calculate the osmotic pressure at 20.°C of each of the following solutions; assume complete dissociation for any ionic solutes: (a) 0.050 M $C_{12}H_{22}O_{11}$(aq); (b) 0.0010 M NaCl(aq); (c) a saturated aqueous solution of AgCN of solubility 23 μg/100. g of water.

9.72 Calculate the osmotic pressure at 20°C of each of the following solutions; assume complete dissociation of ionic compounds: (a) 3.0×10^{-3} M $C_6H_{12}O_6$(aq); (b) 2.0×10^{-3} M $CaCl_2$(aq); (c) 0.010 M K_2SO_4(aq).

9.73 Catalase, a liver enzyme, dissolves in water. A 10.0-mL solution containing 0.166 g of catalase exhibits an osmotic pressure of 1.2 Torr at 20.°C. What is the molar mass of catalase?

9.74 Intravenous medications are often administered in 5.0% glucose, $C_6H_{12}O_6$(aq), by mass. What is the osmotic pressure of such solutions at 37°C (body temperature)? Assume that the density of the solution is 1.0 g·mL^{-1}.

Binary Liquid Mixtures

9.75 Benzene, C_6H_6, and toluene, $C_6H_5CH_3$, form an ideal solution. The vapor pressure of benzene is 94.6 Torr and that of toluene is 29.1 Torr at 25°C. Calculate the vapor pressure of each of the following solutions and the mole fraction of each substance in the vapor phase above those solutions at 25°C: (a) 1.50 mol C_6H_6 mixed with 0.50 mol $C_6H_5CH_3$; (b) 15.0 g of benzene mixed with 64.3 g of toluene.

9.76 Hexane, C_6H_{14}, and cyclohexane, C_6H_{12}, form an ideal solution. The vapor pressure of hexane is 151 Torr and that of cyclohexane is 98 Torr at 25.0°C. Calculate the vapor pressure of each of the following solutions and the mole fraction of each substance in the vapor phase above those solutions at 25°C: (a) 0.25 mol C_6H_{14} mixed with 0.65 mol C_6H_{12}; (b) 10.0 g of hexane mixed with 10.0 g of cyclohexane.

9.77 1,1-Dichloroethane, CH_3CHCl_2, has a vapor pressure of 228 Torr at 25°C; at the same temperature, 1,1-dichlorotetrafluoroethane, CF_3CCl_2F, has a vapor pressure of 79 Torr. What mass of 1,1-dichloroethane must be mixed with 100.0 g of 1,1-dichlorotetrafluoroethane to give a solution with vapor pressure 157 Torr at 25°C? Assume ideal behavior.

9.78 Butanone, $CH_3CH_2COCH_3$, has a vapor pressure of 100. Torr at 25°C; at the same temperature, propanone, CH_3COCH_3, has a vapor pressure of 222 Torr. What mass of propanone must be mixed with 350.0 g of butanone to give a solution with a vapor pressure of 135 Torr? Assume ideal behavior.

9.79 Which of the following mixtures would you expect to show a positive deviation, negative deviation, or no deviation (that is, form an ideal solution) from Raoult's law? Explain your conclusion. (a) methanol, CH_3OH, and ethanol, CH_3CH_2OH; (b) HF and H_2O; (c) hexane, C_6H_{14}, and H_2O.

9.80 Which of the following mixtures would you expect to show a positive deviation, negative deviation, or no deviation (that is, form an ideal solution) from Raoult's law? Explain your conclusion. (a) HBr and H_2O; (b) formic acid, HCOOH, and benzene; (c) cyclopentane, C_5H_{10}, and cyclohexane, C_6H_{12}.

Impact on Biology and Materials

9.81 Distinguish between a foam and a sol. Give at least one example of each.

9.82 Distinguish between an emulsion and a gel. Give at least one example of each.

9.83 Some colloidal suspensions, such as that in Fig. 9.47, appear at first glance to be solutions. What quick, simple procedure can you use to distinguish colloids from solutions?

9.84 Puddings contain large starch molecules that cause the mixture to thicken by a mechanism similar to that by which gelatin thickens. Which is the best description of how puddings thicken? Explain your choice. (a) The starch molecules in pudding are insoluble in water and precipitate when mixed with water. (b) The strands of the starch molecules connect to each other by forming covalent bonds with each other. (c) The starch molecules form hydrogen bonds with water and encapsulate the water in a network. (d) The water molecules hydrate the starch molecules in pudding and the heat of hydration causes the starch molecules to decompose.

Integrated Exercises

9.85 Are the water molecules oriented in the same way or differently around the cations and anions when sodium chloride dissolves? Explain your conclusion.

9.86 When sodium chloride dissolves in water, can a chloride ion be removed from the crystal by one water molecule, or are several required to remove it? Explain your answer.

9.87 Complete the following statements about the effect of intermolecular forces on the physical properties of a substance. (a) The higher the boiling point of a liquid, the (stronger, weaker) are its intermolecular forces. (b) Substances with strong intermolecular forces have (high, low) vapor pressures. (c) Substances with strong intermolecular forces typically have (high, low) surface tensions. (d) The higher the vapor pressure of a liquid, the (stronger, weaker) are its intermolecular forces. (e) Because nitrogen, N_2, has (strong, weak) intermolecular forces, it has a (high, low) critical temperature. (f) Substances with high vapor pressures have correspondingly (high, low) boiling points. (g) Because water has a high boiling point, it must have (strong, weak) intermolecular forces and a correspondingly (high, low) enthalpy of vaporization.

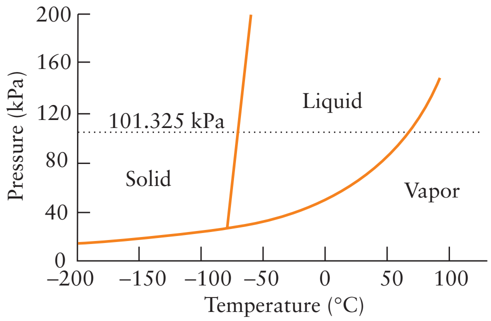
9.88 Hydrogen peroxide, H_2O_2, is a syrupy liquid with a vapor pressure lower than that of water and a boiling point of 152°C. Account for the differences between these properties and those of water.

9.89 Explain the effect that an increase in temperature has on each of the following properties: (a) viscosity; (b) surface tension; (c) vapor pressure; (d) evaporation rate.

9.90 Explain how the vapor pressure of a liquid is affected by each of the following changes in conditions: (a) an increase in temperature; (b) an increase in surface area of the liquid; (c) an increase in volume above the liquid; (d) the addition of air to the volume above the liquid.

9.91 You have two beakers: one is filled with tetrachloromethane and the other with water. You also have two compounds, butane ($CH_3CH_2CH_2CH_3$) and calcium chloride. (a) In which liquid will butane dissolve? Sketch the local environment of the solute in the solution. (b) In which solvent will calcium chloride dissolve? Sketch the local environment of the solute in the solution.

9.92 Use the phase diagram for compound X below to answer these questions: (a) Is X a solid, liquid, or gas at normal room temperatures? (b) What is the normal melting point of X? (c) What is the vapor pressure of liquid X at −50°C? (d) What is the vapor pressure of solid X at −100°C?



9.93 Relative humidity at a particular temperature is defined as

$$\text{Relative humidity} = \frac{\text{partial pressure of water}}{\text{vapor pressure of water}} \times 100\%$$

The vapor pressure of water at various temperatures is given in Table 9.3. (a) What is the relative humidity at 30.°C when the partial pressure of water is 25.0 Torr? (b) Explain what would be observed if the temperature of the air were to fall to 25°C.

9.94 Suppose that 10.0 g of an organic compound used as a component of mothballs is dissolved in 80.0 g of benzene. The freezing point of the solution is 1.20°C. (a) What is an approximate molar mass of the organic compound? (b) An elemental analysis of that substance indicated that the empirical formula is C_3H_2Cl. What is its molecular formula? (c) Using the atomic molar masses from the periodic table, calculate a more accurate molar mass of the compound.

9.95 When a molar mass is determined from freezing-point depression, it is possible to make each of the following errors (among others). In each case, predict whether the error would cause the reported molar mass to be greater or less than the actual molar mass. (a) There was dust on the balance, causing the mass of solute to appear greater than it actually was. (b) The water was measured by volume, assuming a density of 1.00 $g{\cdot}cm^{-3}$, but the water was warmer and less dense than assumed. (c) The thermometer was not calibrated accurately, and so the temperature of the freezing point was actually 0.5°C higher than recorded. (d) The solution was not stirred sufficiently, and so not all the solute dissolved.

9.96 An elemental analysis of epinephrine resulted in the following composition: 59.0% carbon, 26.2% oxygen, 7.15% hydrogen, and 7.65% nitrogen by mass. When 0.64 g of epinephrine was dissolved in 36.0 g of benzene, the freezing point decreased by 0.50°C. (a) Determine the empirical formula of epinephrine. (b) What is the molar mass of epinephrine? (c) Deduce the molecular formula of epinephrine.

9.97 Interpret the following verse from the Coleridge's *Rime of the Ancient Mariner*:

Water, water, every where,
And all the boards did shrink,
Water, water every where,
Nor any drop to drink.

9.98 The vapor pressure of ethanol at 25°C is 58.9 Torr. A sample of ethanol vapor at 25°C and 58.9 Torr partial pressure is in equilibrium with a very small amount of liquid ethanol in a 10.0-L container also containing dry air, at a total pressure of 750.0 Torr. The volume of the container is then reduced at constant temperature to 5.0 L. (a) What is the partial pressure of ethanol in the smaller volume? Explain your reasoning. (b) What is the total pressure of the mixture?

9.99 The height of a column of liquid that can be supported by a given pressure is inversely proportional to its density. An aqueous solution of 0.010 g of a protein in 10. mL of water at 20.°C shows a rise of 5.22 cm in the apparatus shown in Fig. 9.31. Assume the density of the solution to be 0.998 $g{\cdot}cm^{-3}$ and the density of mercury to be 13.6 $g{\cdot}cm^{-3}$. (a) What is the molar mass of the protein? (b) What is the freezing point of the solution? (c) Which colligative property is best for measuring the molar mass of these large molecules? Give reasons for your answer.

9.100 A 0.020 M $C_6H_{12}O_6(aq)$ solution (glucose) is separated from a 0.050 M $CO(NH_2)_2(aq)$ solution (urea) by a semipermeable membrane at 25°C. For both compounds $i = 1$. (a) Which solution has the higher osmotic pressure? (b) Which solution becomes more dilute with the passage of H_2O molecules through the membrane? (c) To which solution should an external pressure be applied to maintain an equilibrium flow of H_2O molecules across the membrane? (d) What external pressure (in atm) should be applied in part (c)?

9.101 Organic chemists once used freezing-point and boiling-point measurements to determine the molar masses of compounds that they had synthesized. When 0.30 g of a nonvolatile solute is dissolved in 30.0 g of CCl_4, the boiling point of the solution is 77.19°C. What is the molar mass of the compound?

9.102 A sample consisting of 155 mg of a purified protein is dissolved in 10.0 mL of ethanol. This solution is placed in a device for measuring osmotic pressure and rises to a final height of 32.5 cm above the level of pure ethanol. The experiment is performed at 1.00 atm and 298 K. The density of ethanol at 298 K is 0.79 $g{\cdot}cm^{-3}$. What is the molar mass of the protein? Assume that the density of the solution is the same as that of pure ethanol. See Exercise 9.99.

9.103 (a) From data in Appendix 2A, derive a numerical form of the Clausius–Clapeyron equation for methanol. (b) Using this equation, plot the appropriate quantities that should give a straight-line relation between vapor pressure and temperature. (c) Estimate the vapor pressure of methanol at 0.0°C. (d) Estimate the normal boiling point of methanol.

9.104 (a) From data in Appendix 2A and Table 7.3, derive a numerical form of the Clausius–Clapeyron equation for benzene. (b) Using this equation, plot the appropriate quantities that should give a straight-line relation between vapor pressure and temperature. (c) Estimate the boiling point of benzene when the external pressure is 0.655 atm. (d) Calculate $S_m°$ for gaseous benzene.

9.105 Colligative properties can be sources of insight into not only the properties of solutions, but also the properties of the solute. For example, acetic acid, CH_3COOH, behaves differently in two different solvents. (a) The freezing point of a 5.00% by mass aqueous acetic acid solution is −1.72°C. What is the molar mass of the solute? Explain any discrepancy between the experimental and the expected molar mass. (b) The freezing-point depression

associated with a 5.00% by mass solution of acetic acid in benzene is 2.32°C. What is the experimental molar mass of the solute in benzene? What can you conclude about the nature of acetic acid in benzene?

9.106 It is standard practice in chemical laboratories to distill high-boiling-point substances under reduced pressure. Trichloroacetic acid has a standard enthalpy of vaporization of 57.814 $kJ \cdot mol^{-1}$ and a standard entropy of vaporization of 124 $J \cdot K^{-1} \cdot mol^{-1}$. Use this information to determine the pressure that one would need to achieve to distill trichloroacetic acid at 80.°C.

9.107 The vapor pressure of phosphoryl chloride difluoride ($OPClF_2$) has been measured as a function of temperature:

Temperature (K)	Vapor pressure (Torr)
190.	3.2
228	68
250.	240.
273	672

(a) Plot ln P against T^{-1} (this project is best done with the aid of a computer or a graphing calculator that can calculate a least-squares fit to the data). (b) From the plot (or a linear equation derived from it) in part (a), determine the standard enthalpy of vaporization of $OPClF_2$; (c) the standard entropy of vaporization of $OPClF_2$; and (d) the normal boiling point of $OPClF_2$. (e) If the pressure of a sample of $OPClF_2$ is reduced to 15 Torr, at what temperature will the sample boil?

9.108 From literature sources, find the critical pressures and temperatures of methane, methylamine (CH_3NH_2), ammonia, and tetrafluoromethane. Discuss the suitability of using each of these solvents for a supercritical extraction at room temperature in an autoclave that can withstand pressures of 100. atm.

9.109 From literature sources, find the critical temperatures for the gaseous hydrocarbons methane, ethane, propane, and butane. Explain the trends observed.

9.110 Consider an apparatus in which A and B are two 1.00-L flasks joined by a stopcock C. The volume of the stopcock is negligible. Initially, A and B are evacuated, the stopcock C is closed, and 1.50 g of diethyl ether, $C_2H_5OC_2H_5$, is introduced into flask A. The vapor pressure of diethyl ether is 57 Torr at −45°C, 185 Torr at 0.°C, 534 Torr at 25°C, and negligible below −86°C. (a) If the stopcock is left closed and the flask is brought to equilibrium at −45°C, what will be the pressure of diethyl ether in flask A? (b) If the temperature is raised to 25°C, what will be the pressure of diethyl ether in the flask? (c) If the temperature of the assembly is returned to −45°C and the stopcock C is opened, what will be the pressure of diethyl ether in the apparatus? (d) If flask A is maintained at −45°C and flask B is cooled with liquid nitrogen (boiling point, −196°C) with the stopcock open, what changes will take place in the apparatus? Assume ideal behavior.

9.111 The apparatus in Exercise 9.110 is again evacuated. Then 35.0 g of chloroform, $CHCl_3$, is placed in flask A and 35.0 g of acetone, CH_3COCH_3, is placed in flask B. The system is allowed to come to equilibrium at 25°C with the stopcock closed. The vapor pressures of chloroform and acetone at 25°C are 195 Torr and 222 Torr, respectively. (a) What is the pressure in each flask at equilibrium? (b) The stopcock is now opened. What will be the final composition of the gas and liquid phases in each flask once the system reaches equilibrium, assuming ideal behavior? (c) Acetone and chloroform solutions show negative deviations from Raoult's law. How will this behavior affect the answers given in part (b)?

9.112 Pentane is a liquid with a vapor pressure of 512 Torr at 25°C; at the same temperature, the vapor pressure of hexane is only 151 Torr. What composition must the liquid phase have if the gas-phase composition is to have equal partial pressures of pentane and hexane?

9.113 Using the Clausius–Clapeyron Equation Living Graph on the Web site for this book, plot on the same set of axes the lines for ΔH_{vap} = 15, 20., 25, and 30. Is the vapor pressure of a liquid more sensitive to changes in temperature if ΔH_{vap} is small or large? Explain your conclusion.

9.114 A pair of amino acids is separated in a column in which the stationary phase is saturated with water and the carrier solvent is methanol, CH_3OH. The more polar the acid, the more strongly it is adsorbed by the stationary phase. The amino acids that were separated in this column are (a) $HOOCCHNH_2CH_2COOH$ and (b) $HOOCCHNH_2CH(CH_3)_2$. Which amino acid would you expect to be eluted first? Explain your reasoning. Refer to Major Technique 4 on chromatography, which follows this chapter.

9.115 Compounds A and B were extracted from a sample of Martian soil. A mixture of 0.52 mg of A and 2.30 mg of B in 1.00 mL of solution was separated by gas chromatography. The areas of the two peaks were 5.44 cm^2 for A and 8.72 cm^2 for B. A second solution contained an extract with an unknown amount of A. To determine the concentration of A in the solution, 2.00 mg of B was added to 2.0 mL of the solution, which was then introduced into a gas chromatograph. Peak areas of 3.52 cm^2 for A and 7.58 cm^2 for B were measured. What is the concentration of A in the second solution? Refer to Major Technique 4, which follows this chapter.

9.116 Pure liquid naphthalene freezes at 80.2°C at 1 atm. When 1.00 mol of any nonelectrolyte solute is dissolved in 1.00 kg of naphthalene, the new freezing point of the solution (at 1 atm) is 73.2°C. When 14.8 g of sulfur is dissolved in 575 g of naphthalene, the new freezing point of the solution is 79.5°C. What are the molar mass and the molecular formula of the sulfur species in solution?

9.117 Human blood has an osmotic pressure relative to water of approximately 7.7 atm at body temperature (37°C). In a hospital, intravenous glucose ($C_6H_{12}O_6$) solutions are often given. If a technician must mix 500. mL of a glucose solution for a patient, what mass of glucose should be used?

9.118 In heavy water, D_2O, deuterium atoms replace the hydrogen atoms. The hydrogen bonds in heavy water are stronger than those in normal water. (a) How will the vapor pressure of a sample of H_2O be affected if 10% of the water molecules are replaced by D_2O molecules? (b) Calculate the molality of the D_2O in the solution.

9.119 What volume of 0.010 M NaOH(aq) is required to react completely with 30. g of an aqueous acetic acid solution in which the mole fraction of acetic acid is 0.15?

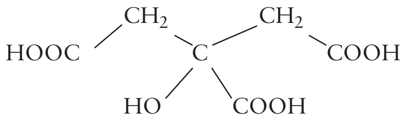
9.120 The combustion analysis of L-carnitine, an organic compound thought to build muscle strength, yielded 52.16% C, 9.38% H, 8.69% N, and 29.78% O. The osmotic pressure of a 100.00-mL solution of 0.322 g of L-carnitine was found to be 0.501 atm at 32°C. Assuming that L-carnitine does not ionize in methanol, determine (a) the molar mass of L-carnitine; (b) the molecular formula of L-carnitine.

9.121 Pentanol, an organic compound with the formula $CH_3CH_2CH_2CH_2CH_2OH$, has molecules with a nonpolar hydrocarbon chain of medium length attached to a polar —OH group. It is insoluble in water. However, if surfactant is added, the molecules of the three compounds form a layered structure that suspends the pentanol in the water. Propose a structure for the layered structure, describing the arrangement of the water, pentanol, and detergent molecules.

9.122 Hydrogen bonding typically occurs between a highly electronegative atom and a hydrogen atom attached to another electronegative atom. (a) Draw the Lewis structures for $CHCl_3$ and $(CH_3)_2CO$ and orient the structures to show the hydrogen bonding between the pair: (b) Which hydrogen atom is considered to have a low electron density and therefore to be a center of positive partial charge, and why?

Chemistry Connections

9.123 Sports drinks provide water to the body in the form of an isotonic solution (one having the same total molar concentration of solutes as human blood). These drinks contain electrolytes such as NaCl and KCl as well as sugar and flavoring. One of the main flavoring agents in sport drinks is citric acid, shown below.



Citric acid

(a) Indicate the hybridization of each C atom in citric acid.
(b) Can citric acid take part in hydrogen bonding?
(c) Predict from a consideration of intermolecular forces whether citric acid is a gas, liquid, or solid at 25°C and whether it is soluble in water.
(d) *Normal saline solution* is an isotonic solution containing 0.9% NaCl by mass in water. Assuming complete dissociation of the NaCl, what is the total molar concentration of all solutes in an isotonic solution? Assume a density of 1.00 $g\cdot cm^{-3}$ for the solution.
(e) If you decide to make up 500.0 mL of a sports drink with 1.0 g of NaCl and glucose, what mass of glucose do you need to add to the NaCl and water to make the solution isotonic (see part d)? Assume a density of 1.00 $g\cdot cm^{-3}$ for the solution.
(f) A paramedic treating injuries in a remote area has 300.0 mL of a 1.00% by mass solution of boric acid, $B(OH)_3$, that needs to be made isotonic (assume that the density is 1.00 $g\cdot cm^{-3}$). What mass of NaCl should be added? Assume that the NaCl is completely dissociated in the solution and that the volume of the solution does not change on addition of the NaCl. Take into account the 0.007% deprotonation of boric acid.

Because the scent of a flower may be due to hundreds of different compounds, it is difficult for perfume manufacturers to duplicate floral scents. Establishing the identities and relative amounts of the components of a fragrance was actually impossible until the development of chromatography. Related techniques are used in forensic laboratories to match samples of fluids, by food manufacturers to test product quality, and to search for evidence of life on other planets. All these techniques depend on subtle differences in intermolecular forces to separate compounds.

Solvent Extraction

If an aqueous solution of a compound is shaken with another liquid that is immiscible (mutually insoluble) with water, some of the compound may dissolve in the other solvent. For example, molecular iodine, I_2, is very slightly soluble in water but is highly soluble in tetrachloromethane, CCl_4, which is immiscible with water. When tetrachloromethane is added to water containing iodine, most of the iodine dissolves in the CCl_4. The solute is said to *partition* itself between the two solvents. *Solvent extraction* is used to obtain plant flavors and aromas from aqueous slurries of the plant that have been crushed in a blender.

In some cases, the solids themselves are subjected to extraction by a solvent. For example, in one process used to decaffeinate coffee, the coffee beans are mixed with activated charcoal and a high-pressure stream of "supercritical carbon dioxide" (carbon dioxide at high pressure and above its critical temperature) is passed over them at approximately 90°C. A supercritical solvent is a highly mobile fluid with a very low viscosity. The carbon dioxide removes the soluble caffeine preferentially without extracting the flavoring agents and evaporates without leaving a harmful residue.

Liquid Chromatography

In the early part of the twentieth century, the Russian botanist M. S. Tsvet found a way to separate the many pigments in flowers and leaves. He ground up the plant materials and dissolved the pigments, then poured the solution over the top of a vertical tube of ground chalk. The different pigments trickled through the chalk at different rates, producing colored bands in the tube, inspiring the name *chromatography* ("color writing"). The separation occurred because the different pigments were absorbed to different extents by the chalk.

Chromatography is one of the most powerful and widely used means for separating mixtures, because it is often inexpensive and it can be used to provide quantitative as well as qualitative information. The simplest method is paper chromatography. A drop of solution is placed near the bottom edge of the *stationary phase*, an absorbent support, such as a strip of paper. The *mobile phase*, a fluid solvent, is added below the spot and the solvent is absorbed on the support. As the mobile phase rises up the stationary phase by capillary action, the materials in the spot are carried upward at a rate that depends on how strongly they are adsorbed on (adhere to) the stationary phase (Fig. 1). The more strongly the solute is adsorbed on the stationary phase, the longer it will take to travel up the support.

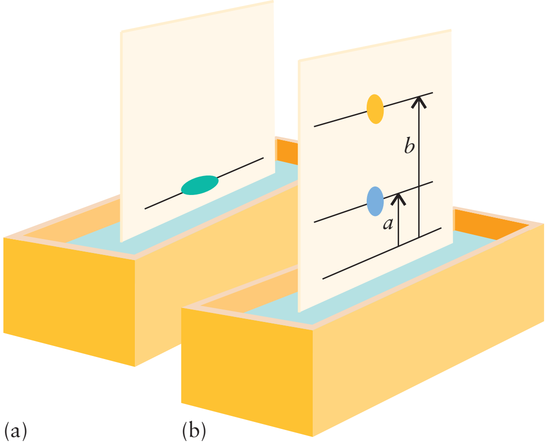


FIGURE 1 Two stages in a paper chromatography separation of a mixture of two components. (a) Before separation; (b) after separation. The relative values of the distances *a* and *b* are used to identify the components.

The same concepts apply to *column chromatography*, where the stationary phase is normally small particles of silica, SiO_2, or alumina, Al_2O_3. These substances are not very reactive and have specially prepared surfaces to increase their adsorption ability. The column is saturated with solvent, and a small volume of solution containing the solutes is poured onto the top. As soon as it has soaked in, more solvent is added. The solutes travel slowly down the column and are *eluted* (removed as fractions) at the bottom (Fig. 2). If the mobile phase is less polar than the stationary phase, the less polar solutes will be eluted first and the more polar ones last.

To improve the separation of the solutes in a mixture, *high-performance liquid chromatography* (HPLC) was developed. In this technique, the mobile phase is forced under pressure through a long, narrow column, yielding an excellent separation in a relatively short time. HPLC has become the primary means of monitoring the use of therapeutic drugs and of detecting drug abuse; it is also used to separate the compounds contributing to the fragrances of flowers.

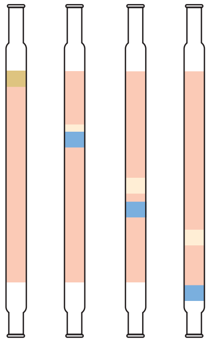

FIGURE 2 A column chromatography experiment. The mixture is placed on top of the column (left). As the solvent passes through the support, the mixture is washed down the column and separates into bands.

(continued)

Self-Test M4.1A A pair of amino acids is separated in a column in which the stationary phase is saturated with water and the mobile phase is methanol, CH_3OH. The more polar the acid, the more strongly it is adsorbed by the stationary phase. The amino acids that were separated in this column are (a) $HOOCCH(NH_2)CH_2OH$ and (b) $HOOCCH(NH_2)CH_3$. Which amino acid will be retained in the column the longest?

[***Answer:*** Compound (a) has more polar groups, because it has an −OH group, and so will be retained longer on the column.]

Self-Test M4.1B Inorganic cations can be separated by liquid chromatography according to their ability to form complexes with chloride ions. For the separation, the stationary phase is saturated with water and the mobile phase is a solution of HCl in acetone. The relative solubilities of the following chlorides in concentrated hydrochloric acid are $CuCl_2 > CoCl_2 > NiCl_2$. What is the order of elution of these compounds?

Gas Chromatography

Volatile compounds can be separated in a *gas chromatograph*, in which the mobile phase is usually a relatively unreactive carrier gas such as helium, nitrogen, or hydrogen. The principles are the same as those for liquid chromatography, but the output is more often a *chromatogram*, rather than a series of eluted samples (Fig. 3). The chromatogram shows when each solute was eluted, and the peak areas tell how much of each component is present. The identity of the solute producing each peak can be determined by comparing its location against a database of known compounds.

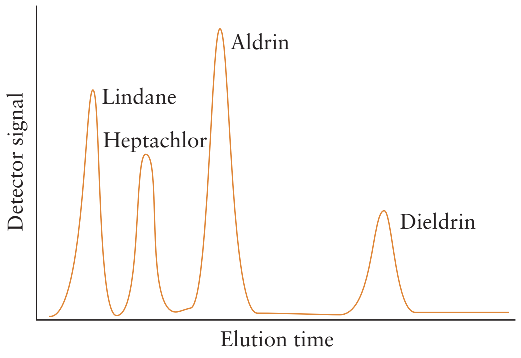

FIGURE 3 A gas chromatogram of a mixture of pesticides from farmland. The relative heights of the peaks indicate the relative abundances of the compounds.

In *gas–liquid partition chromatography* (GLPC), the stationary phase is a liquid that coats the particles in the tube or the walls of the tube. Often the tube itself is very narrow and long, perhaps 100 m, and has to be coiled (Fig. 4). Solutes are separated, as in liquid chromatography, by their relative solubility in the gas and liquid phases. In *gas–solid adsorption chromatography*, solid particles coat the inside of the narrow tube. The solute vapors are separated by their relative attraction for the solid particles. In both cases, it is relative polarity that determines the distances between peaks.

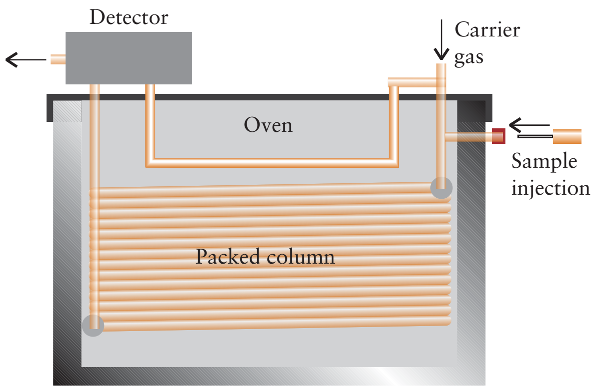

FIGURE 4 A schematic representation of the arrangement in a gas chromatograph. The coiled column, which is packed with the stationary phase, may be as long as 100 m.

As the vapor leaves the tube, the compounds in the sample are detected by a device such as a thermal conductivity detector. This instrument continuously measures the thermal conductivity (the ability to conduct heat) of the carrier gas, which changes when a solute is present. The detection techniques are very sensitive, allowing tiny amounts of solutes to be detected. Many environmental monitoring and forensic applications have been developed.

Gas Chromatography–Mass Spectrometry

Some detectors can give additional information about the *elutes* (the eluted solutes). One example is the *gas chromatograph–mass spectrometer* (GC-MS), which produces a mass spectrum of each compound as well as its mass and location in the chromatogram.* This powerful means of detection can be used when standard samples are not available to help determine the identities of the solutes. A beam of ions bombards each compound as it emerges from the chromatograph. The compound breaks up into ions of different masses, providing a spread of narrow peaks instead of one peak for each compound. The relative amount of each fragment is determined and used to help identify the compound.

The GC-MS instrument can be very compact and used in mobile equipment. A GC-MS device was used on the Viking Lander on the first Mars mission to search for organic compounds that would have provided evidence of life (none was detected).

What Are the Key Ideas? Instead of going to completion, reactions proceed until the composition of a reaction mixture corresponds to minimum Gibbs free energy. This composition is described by an equilibrium constant that is characteristic of the reaction. The equilibrium is dynamic and responds to changes in the conditions.

Why Do We Need to Know This Material? The dynamic equilibrium toward which every chemical reaction tends is such an important aspect of the study of chemistry that the next four chapters deal with it. We need to know the composition of a reaction mixture at equilibrium because it tells us how much product we can expect. To control the yield of a reaction, we need to understand the thermodynamic basis of equilibrium and how the position of equilibrium is affected by conditions such as temperature and pressure. The response of equilibria to changes in conditions has considerable economic and biological significance: the regulation of chemical equilibrium affects the yields of products in industrial processes, and living cells struggle to avoid sinking into equilibrium.

What Do We Need to Know Already? The concepts of chemical equilibrium are related to those of physical equilibrium (Sections 9.1–9.3). Because chemical equilibrium depends on the thermodynamics of chemical reactions, we shall need to use the Gibbs free energy of reaction (Section 8.13) and standard enthalpies of formation (Section 7.18). Chemical equilibrium calculations require a thorough knowledge of molar concentration (Section G), reaction stoichiometry (Section L), and the gas laws (Chapter 4).

Early in the twentieth century, the looming prospect of World War I created a desperate need for nitrogen compounds because nitrates normally used for agriculture were being made into explosives. Almost all the nitrates used for fertilizers and explosives were quarried from deposits in Chile, and the limited supply could not keep up with the demand. Moreover, shipping channels were vulnerable to attack, which threatened to cut off the supply altogether. Although nitrogen is abundant in air, the methods used at the time to convert nitrogen into compounds were too costly to employ on a large scale. Any nation that could develop an economical process to **fix** atmospheric nitrogen—that is, to combine it with other elements—would have all the nitrogen compounds it needed.

Scientists on both sides of the conflict were urgently seeking ways to fix nitrogen. Finally, through determination, application, and—as so often happens in research—a bit of luck, the German chemist Fritz Haber in collaboration with the chemical engineer Carl Bosch found an economical way to harvest the nitrogen of the air and to provide an abundant source of compounds for both agriculture and armaments.

One difficulty Haber faced is that the reactions used to produce compounds from nitrogen do not go to completion, but appear to stop after only some of the reactants have been used up. At this point the mixture of reactants and products has reached **chemical equilibrium,** the stage in a chemical reaction when there is no further tendency for the composition of the reaction mixture—the concentrations or partial pressures of the reactants and products—to change. To achieve the greatest conversion of nitrogen into its compounds, Haber had to understand how a reaction approaches and eventually reaches equilibrium and then use that knowledge—as we shall see in Section 10.12—to improve the yield by changing the conditions of the reaction.

Like physical equilibria, all chemical equilibria are dynamic equilibria, with the forward and reverse reactions occurring at the same rate. In Chapter 9, we considered several physical processes, including vaporizing and dissolving, that reach dynamic equilibrium. This chapter shows how to apply the same ideas to chemical changes. It

And, we might add, to change the course of history.

also shows how to use thermodynamics to describe equilibria quantitatively, which puts enormous power into our hands—the power to control the direction of a reaction and the yield of products. We first show that a single quantity, the *equilibrium constant*, characterizes the composition of a reaction mixture at equilibrium. Then we explore how the equilibrium constant arises from thermodynamics and see how it is related to the free energy of the reaction. We then see how to use the equilibrium constant to calculate the equilibrium composition of a reaction mixture. Finally, we develop thermodynamic arguments to deduce how the composition of a reaction mixture at equilibrium responds to changes in the conditions under which the reaction is taking place.

REACTIONS AT EQUILIBRIUM

To say that chemical equilibrium is dynamic means that when a reaction has reached equilibrium, the forward and reverse reactions continue to take place, but with reactants being formed as fast as they are consumed. As a result, the composition of the reaction mixture remains constant. To develop these ideas we first establish that reactions can take place in their reverse direction as soon as some products have accumulated. Then we see how to relate the equilibrium composition to the thermodynamic properties of the system.

10.1 The Reversibility of Reactions

Some reactions, such as the explosive reaction of hydrogen and oxygen, appear to proceed to completion, but others seem to stop at an early stage. For example, consider the reaction that took place when Haber heated nitrogen and hydrogen under pressure in the presence of a small amount of the metal osmium:

The metal acts as a catalyst for this reaction, a substance that helps to make a reaction go faster (Section 14.14). Osmium is too expensive to be used commercially: in the industrial process, iron is used instead.

$$N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g) \qquad \textbf{(A)}$$

The reaction does produce ammonia rapidly at first, but eventually the reaction seems to stop (Fig. 10.1). As the graph shows, no matter how long we wait, no more product forms. The reaction has reached equilibrium.

Like phase changes, chemical reactions tend toward a *dynamic* equilibrium in which, although there is no net change, the forward and reverse reactions are still taking place, but at matching rates. What actually happens when the formation of ammonia *appears* to stop is that the rate of the reverse reaction,

$$2\,NH_3(g) \longrightarrow N_2(g) + 3\,H_2(g) \qquad \textbf{(B)}$$

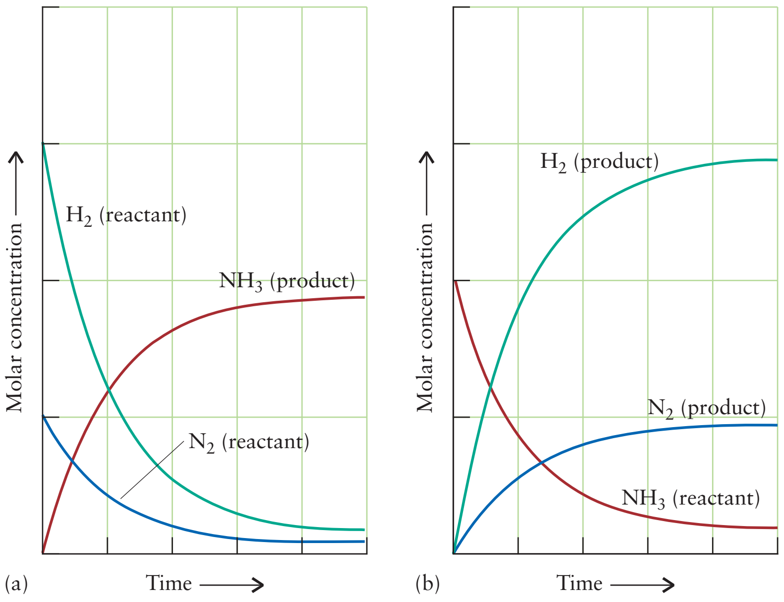

FIGURE 10.1 (a) In the synthesis of ammonia, the concentrations of N_2 and H_2 decrease with time and that of NH_3 increases until they finally settle into values corresponding to a mixture in which all three are present and there is no further net change. (b) If the experiment is repeated with pure ammonia, it decomposes, and the composition settles down into a mixture of ammonia, nitrogen, and hydrogen. (The two graphs correspond to experiments at two different temperatures, and so they correspond to different equilibrium compositions.)

(a) (b) (c)

FIGURE 10.2 (a) Methane burns in air with a steady flame but, because matter is being added and removed, the reaction is not at equilibrium. (b) This sample of glucose in air is unchanging in composition, but it is not yet in equilibrium with its combustion products; the reaction proceeds far too slowly at room temperature. (c) Nitrogen dioxide (a brown gas) and dinitrogen tetroxide (a colorless volatile solid) are in equilibrium in this vessel. We can tell that they are by changing the temperature slightly and seeing the composition adjust to a new value.

Lab Video 10.2

increases as more ammonia is formed. At equilibrium, the ammonia is decomposing as fast as it is being formed. Just as we did for phase transitions, we express this state of dynamic equilibrium by replacing the arrow in the equation with equilibrium "harpoons":

$$N_2(g) + 3\,H_2(g) \rightleftharpoons 2\,NH_3(g) \qquad \text{(C)}$$

All chemical equilibria are dynamic equilibria. Although there is no further net change at equilibrium, the forward and reverse reactions are still taking place. As we shall see later in the chapter, dynamic equilibria respond to changes in temperature and pressure, and the addition of even a small amount of additional reagent can result in a change in overall composition. A reaction that is simply not taking place (such as a mixture of hydrogen and oxygen at room temperature and pressure) does not respond to small changes in the conditions and therefore is not at equilibrium.

Thinking point: Can you think of an experiment to show that a chemical equilibrium is dynamic? Think, perhaps, about using radioactive isotopes.

We can use these characteristics to decide if the three systems in Fig. 10.2 are at equilibrium. All three systems appear to be unchanging. However, when methane, CH_4, burns with a steady flame to form carbon dioxide gas and water (Fig. 10.2a), the combustion reaction is not at equilibrium because the composition is not constant (reactants continue to be added and the products dissipate instead of reacting). The sample of glucose does not change (Fig. 10.2b), even if we leave it for a very long time. However, the glucose is not at equilibrium with the products of its combustion (carbon dioxide and water); it survives only because the rate of its combustion is immeasurably slow at room temperature. The gas-phase reaction (Fig. 10.2c), however, is at equilibrium because, as well as the composition being constant, additional experiments show that NO_2 is ceaselessly forming N_2O_4 and that N_2O_4 is decomposing into NO_2 at the same rate.

The criteria that identify a dynamic chemical equilibrium are:

1 The forward reaction and its reverse are both taking place.

2 They are doing so at equal rates (so there is no net change).

Chemical reactions reach a state of dynamic equilibrium in which the rates of forward and reverse reactions are equal and there is no net change in composition.

10.2 Equilibrium and the Law of Mass Action

In 1864, before Haber began his work, the Norwegians Cato Guldberg (a mathematician) and Peter Waage (a chemist) had discovered the mathematical relation that summarizes the composition of a reaction mixture at equilibrium. As an example of their approach, look at the data in Table 10.1 for the reaction between SO_2 and O_2:

$$2\,SO_2(g) + O_2(g) \rightleftharpoons 2\,SO_3(g) \qquad \text{(D)}$$

TABLE 10.1 Equilibrium Data and the Equilibrium Constant for the Reaction $2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$ at 1000. K

P_{SO_2} (bar)	P_{O_2} (bar)	P_{SO_3} (bar)	K*
0.660	0.390	0.0840	0.0415
0.0380	0.220	0.00360	0.0409
0.110	0.110	0.00750	0.0423
0.950	0.880	0.180	0.0408
1.44	1.98	0.410	0.0409

*Average K: 0.0413

In each of these five experiments, a mixture with different initial compositions of the three gases was prepared and allowed to reach equilibrium at 1000. K. The compositions of the equilibrium mixtures and the total pressure P were then determined. At first, there seemed to be no pattern in the data. However, Guldberg and Waage noticed an extraordinary relation: the value of the quantity

$$K = \frac{(P_{SO_3}/P°)^2}{(P_{SO_2}/P°)^2(P_{O_2}/P°)}$$

was nearly the same for every experiment, regardless of the initial compositions. Here, P_J is the equilibrium partial pressure of gas J and $P° = 1$ bar, the standard pressure. Note that K is unitless, because the units of P_J are canceled by the units of $P°$ in each term. From now on, though, to keep the notation simple, we shall write simply

$$K = \frac{(P_{SO_3})^2}{(P_{SO_2})^2 P_{O_2}}$$

with the P_J understood to be the numerical value of the pressure in bars.

Within experimental error, Guldberg and Waage obtained the same value of K whatever the initial composition of the reaction mixture. This remarkable result shows that K is characteristic of the composition of the reaction mixture at equilibrium at a given temperature. It is known as the **equilibrium constant** for the reaction. The **law of mass action** summarizes this result: it states that, *at equilibrium, the composition of the reaction mixture can be expressed in terms of an equilibrium constant* where, for any reaction between gases that can be treated as ideal,

$$K = \left\{\frac{\text{partial pressures of products}}{\text{partial pressures of reactants}}\right\}_{\text{equilibrium}} \quad \textbf{(1a)}$$

with each partial pressure raised to a power equal to the corresponding stoichiometric coefficient in the balanced chemical equation for the reaction. We shall not in general write "equilibrium" on expressions for K. Thus, if we are interested in the reaction

$$a\ A(g) + b\ B(g) \rightleftharpoons c\ C(g) + d\ D(g) \quad \textbf{(E)}$$

and if all the gases are treated as ideal, we write

$$K = \frac{(P_C)^c(P_D)^d}{(P_A)^a(P_B)^b} \quad \textbf{(1b)*}$$

with the numerical values of the partial pressures being those at equilibrium (in bar).

EXAMPLE 10.1 Writing the expression for an equilibrium constant

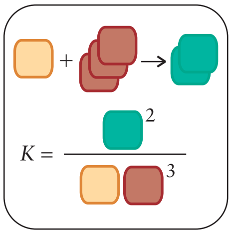
Write the equilibrium constant for the ammonia synthesis reaction, reaction C.

PLAN Write the equilibrium constant with the partial pressure of the product in the numerator, raised to a power equal to its coefficient in the balanced equation. Do the same for the reactants, but place their partial pressures in the denominator:

SOLVE

From $K = (P_C)^c(P_D)^d/(P_A)^a(P_B)^b$,

$$K = \frac{(P_{NH_3})^2}{P_{N_2}(P_{H_2})^3}$$



As already explained, each P_J in this expression should be interpreted as $P_J/P°$.

Self-Test 10.1A Write the expression for the equilibrium constant for the reaction $4\,NH_3(g) + 5\,O_2(g) \rightleftharpoons 4\,NO(g) + 6\,H_2O(g)$.

[***Answer:*** $K = (P_{NO})^4(P_{H_2O})^6/(P_{NH_3})^4(P_{O_2})^5$]

Self-Test 10.1B Write the expression for the equilibrium constant for $2\,H_2S(g) + 3\,O_2(g) \rightleftharpoons 2\,SO_2(g) + 2\,H_2O(g)$.

We use a different measure of concentration when writing expressions for the equilibrium constants of reactions that involve species other than gases. Thus, for a species J that forms an ideal liquid or solid solution, the partial pressure in the expression for K is replaced by the molarity [J] relative to the standard molarity $c° = 1$ mol·L^{-1}. Although K should be written in terms of the dimensionless ratio $[J]/c°$, it is common practice to write K in terms of [J] alone and to interpret each [J] as the molarity with the units struck out. It has been found empirically, and is justified by thermodynamics, that pure liquids or solids should not appear in K. So, even though $CaCO_3(s)$ and $CaO(s)$ occur in the equilibrium

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g) \quad \textbf{(F)}$$

neither appears in the equilibrium constant, which is $K = P_{CO_2}/P°$ (or, more simply, $K = P_{CO_2}$).

We can summarize these empirical rules by introducing the concept of the **activity,** a_J, of a substance J:

Substance	Activity	Simplified form
Ideal gas	$a_J = P_J/P°$	$a_J = P_J$
Solute in a dilute solution	$a_J = [J]/c°$	$a_J = [J]$
Pure solid or liquid	$a_J = 1$	$a_J = 1$

Note that all activities are pure numbers and thus are unitless. When using the simplified form of the equilibrium constant, the activity is the numerical value of the pressure in bar or the numerical value of the molarity in moles per liter.

At this stage, activities are simply quantities introduced to facilitate writing the expression for K. In advanced work, activities are used to take into account deviations from ideal behavior and to accommodate real gases and real solutions, where intermolecular interactions are important. In those cases the activity of a substance may differ from the calculated pressure or concentration. However, for the low-pressure gases and dilute solutions that concern us here, we can ignore the interactions between molecules and regard activities as providing a simple, uniform way of writing general expressions for equilibrium constants and other quantities that we shall meet shortly. We have to remember, though, that because we are assuming ideal behavior, our expressions are approximations.

Thinking point: How might intermolecular and interionic interactions affect the value of an activity?

The use of activities allows us to write a general expression for the equilibrium constant for any reaction:

$$K = \left\{\frac{\text{activities of products}}{\text{activities of reactants}}\right\}_{\text{equilibrium}} \quad \textbf{(2a)}$$

More specifically, for a generalized version of reaction E, with phases not specified:

$$a\,\mathrm{A(g)} + b\,\mathrm{B(g)} \rightleftharpoons c\,\mathrm{C(g)} + d\,\mathrm{D(g)} \qquad K = \frac{(a_\mathrm{C})^c(a_\mathrm{D})^d}{(a_\mathrm{A})^a(a_\mathrm{B})^b} \qquad \textbf{(2b)*}$$

Because activities are unitless, so too is K.

A note on good practice: In some cases you will see an equilibrium constant denoted K_P to remind you that it is expressed in terms of partial pressures. However, the subscript P is unnecessary because, by definition, equilibrium constants for gas-phase reactions are expressed in terms of partial pressures.

Chemical equilibria with reactants and products that are all in the same phase are called **homogeneous equilibria.** Equilibria C, D, and E are homogeneous. Equilibria in systems having more than one phase are called **heterogeneous equilibria.** Equilibrium F is heterogeneous; so too is the equilibrium between water vapor and liquid water in a closed system:

$$H_2O(l) \rightleftharpoons H_2O(g) \qquad \textbf{(G)}$$

In this reaction, there is a gas phase and a liquid phase. Likewise, the equilibrium between a solid and its saturated solution is heterogeneous:

$$Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\,OH^-(aq) \qquad \textbf{(H)}$$

The equilibrium constants for heterogeneous reactions are also given by the general expression in Eq. 2: all we have to remember is that the activity of a pure solid or liquid is 1. For instance, for the calcium hydroxide equilibrium (reaction H),

$$K = \frac{a_{\mathrm{Ca^{2+}}}(a_{\mathrm{OH^-}})^2}{\underbrace{a_{\mathrm{Ca(OH)_2}}}_{\text{1 for a pure solid}}} = [\mathrm{Ca^{2+}}][\mathrm{OH^-}]^2$$

because the calcium hydroxide is a pure solid. The calcium hydroxide must be present for the equilibrium to exist, but it does not appear in the expression for the equilibrium constant. Remember that each [J] represents the molar concentration of J with the units struck out. Similarly, in the equilibrium between solid nickel, gaseous carbon monoxide, and gaseous nickel carbonyl used in the purification of nickel,

$$\mathrm{Ni(s)} + 4\,\mathrm{CO(g)} \rightleftharpoons \mathrm{Ni(CO)_4(g)} \qquad K = \frac{a_{\mathrm{Ni(CO)_4}}}{\underbrace{a_{\mathrm{Ni}}}_{1}(a_{\mathrm{CO}})^4} = \frac{P_{\mathrm{Ni(CO)_4}}}{(P_{\mathrm{CO}})^4}$$

As for the calcium hydroxide equilibrium, solid nickel must be present for the equilibrium to exist, but it does not appear in the expression for the equilibrium constant.

Self-Test 10.2A Write the equilibrium constant for the equilibrium between atmospheric oxygen and oxygen dissolved in water, $O_2(g) \rightleftharpoons O_2(aq)$.

[***Answer:*** $K = [O_2]/P_{O_2}$]

Self-Test 10.2B Write the equilibrium constant for the equilibrium $Zn(s) + 2\,HCl(aq) \rightleftharpoons ZnCl_2(aq) + H_2(g)$.

Some reactions in solution involve the solvent as a reactant or product. When the solution is very dilute, the change in solvent concentration due to the reaction is insignificant. In such cases, the solvent is treated as a pure substance and ignored when writing K. In other words,

For a nearly pure solvent: $a_{\text{solvent}} = 1$

A final point is that, when a reaction involves fully dissociated ionic compounds in solution, then the equilibrium constant should be written for the net ionic equation, by using the activity for each type of ion.

Self-Test 10.3A Write the equilibrium constant for the reaction of silver nitrate with sodium hydroxide: $2\ AgNO_3(aq) + 2\ NaOH(aq) \rightleftharpoons Ag_2O(s) + 2\ NaNO_3(aq) + H_2O(l)$. Remember to use the net ionic equation.

[***Answer:*** $K = 1/[Ag^+]^2[OH^-]^2$]

Self-Test 10.3B Write the equilibrium constant K for $P_4(s) + 5\ O_2(g) \rightleftharpoons P_4O_{10}(s)$.

Each reaction has its own characteristic equilibrium constant, with a value that can be changed only by varying the temperature (Table 10.2). The extraordinary empirical result, which we justify in the next section, is that, *regardless of the initial composition of a reaction mixture, the composition tends to adjust until the activities give rise to the characteristic value of K for the reaction and temperature* (Fig. 10.3).

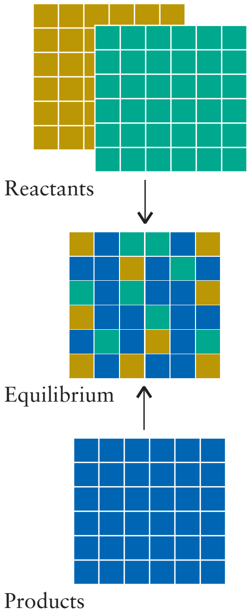


FIGURE 10.3 Whether we start with pure reactants or with pure products, a reaction mixture will always tend toward a mixture of reactants and products that has a composition in accord with the equilibrium constant for the reaction at the temperature of the experiment.

*Three significant figures

†K_c is the equilibrium constant in terms of molar concentrations of gases (Section 10.6).

The equilibrium composition of a reaction mixture is described by the equilibrium constant, which is equal to the activities of the products (raised to powers equal to their stoichiometric coefficients in the balanced chemical equation for the reaction) divided by the activities of the reactants (raised to powers equal to their stoichiometric coefficients).

10.3 The Thermodynamic Origin of Equilibrium Constants

Guldberg and Waage's description of equilibrium was entirely empirical. Now, though, chemists know that the law of mass action is a consequence of thermodynamics and that the apparently mysterious form of K arises from thermodynamic considerations and ultimately from the expression for the entropy of mixing of reactants and products as the latter are formed. The Gibbs free energy of a reaction mixture depends on the partial pressures or concentrations of reactants and products. Therefore, the tendency of a reaction to go in the forward or the reverse direction is determined by those pressures or concentrations.

Every chemical reaction has a tendency to proceed spontaneously toward equilibrium, but the direction of reaction depends on the composition of the reaction mixture. At constant temperature and pressure:

- In a reaction mixture that has not yet produced enough products to reach equilibrium, the spontaneous direction of change is toward more products and $\Delta G < 0$ for the forward reaction.
- In a reaction mixture that has excess products, the *reverse* reaction is spontaneous and $\Delta G > 0$ for the forward reaction (so that $\Delta G < 0$ for the reverse reaction).
- For the reaction at equilibrium, there is no tendency for spontaneous change in either the forward or the reverse direction and $\Delta G = 0$.

Clearly, ΔG changes as the proportions of reactants and products change; the composition of the reaction mixture at equilibrium is the composition at which ΔG is zero (Fig. 10.4). As we can see from the graph, at any point during the reaction the sign of ΔG is indicated by the slope of the curve, which shows how G varies with composition at that point: to the left of the equilibrium composition, the slope is negative and so the forward reaction is spontaneous; to the right of equilibrium, the slope is positive and so the reverse reaction is spontaneous; at equilibrium, at the minimum of the curve, the slope is zero.

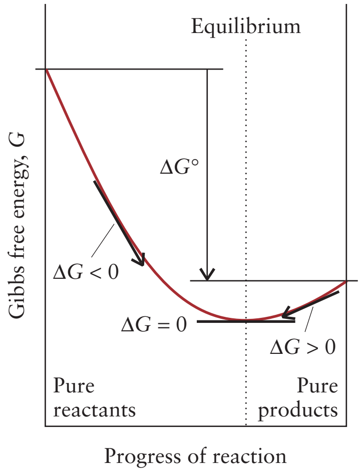

FIGURE 10.4 The variation of Gibbs free energy of a reaction mixture with composition. A reaction mixture has a spontaneous tendency to change in the direction of decreasing Gibbs free energy. Note that ΔG is the *slope* of the line at each composition, whereas $\Delta G°$ is the difference between the standard Gibbs free energies of the pure reactants and the pure products.

The value of ΔG at a particular stage of the reaction is the difference in the molar Gibbs free energies of the products and the reactants *at the partial pressures or concentrations that they have at that stage*, weighted by the stoichiometric coefficients interpreted as amounts in moles:

$$\Delta G = \sum nG_m(\text{products}) - \sum nG_m(\text{reactants}) \qquad \text{Units: kilojoules} \qquad \textbf{(3a)}$$

(This is Eq. 18 of Chapter 8.) We shall sometimes find it useful to interpret the n that appear in Eq. 3a as pure numbers (rather than amounts in moles), so that if $n = 2$ mol, in this convention we would use $n = 2$. To signal that we are using this "molar" convention ("molar" because the units of ΔG then become kilojoules per mole), we attach a subscript r to ΔG (r for reaction) and write

$$\Delta G_r = \sum nG_m(\text{products}) - \sum nG_m(\text{reactants}) \qquad \text{Units: kilojoules per mole} \qquad \textbf{(3b)}$$

We shall explain later in this section (in the "How Do We Do That?" box) exactly when and why it is necessary to use this "molar" convention.

The molar Gibbs free energies of the reactants and products change during the course of the reaction, so ΔG changes too. It is very important to distinguish this Gibbs free energy of reaction, ΔG, from the *standard* Gibbs free energy of reaction, $\Delta G°$, which does not change during the course of a reaction:

- ΔG is the difference in molar Gibbs free energies of the products and the reactants at a specified stage of the reaction.

- $\Delta G°$ is the difference in molar Gibbs free energies of the products and the reactants in their standard states and can be calculated from the standard Gibbs free energies of formation:

$$\Delta G° = \sum n\Delta G_f°(\text{products}) - \sum n\Delta G_f°(\text{reactants}) \qquad \textbf{(3c)}$$

(This is Eq. 20 of Chapter 8.) We could write this expression in the molar convention too, as $\Delta G_r°$, in which case the n would be interpreted as pure numbers.

A note on good practice: Recall that the standard state of a pure substance is its pure form at a pressure of 1 bar (Section 7.15). For a solute, the standard state is for a concentration of 1 mol·L^{-1}. Pure solids and liquids may always be regarded as being in their standard states provided the pressure is close to 1 bar.

To find how ΔG changes with composition, we need to know how the molar Gibbs free energy of each substance varies with its partial pressure, if it is a gas, or with its concentration, if it is a solute. We have already seen (in Section 9.3) that the molar Gibbs free energy of an ideal gas J is related to its partial pressure, P_J, by

$$G_m(J) = G_m°(J) + RT\ln(P_J/P°) \qquad \textbf{(4a)}$$

Note that, because $\ln 1 = 0$, $G_m(J)$ has its standard value, $G_m°(J)$, when $P_J = 1$ bar. Thermodynamic arguments (which we do not reproduce here) show that a similar expression applies to solutes and pure substances. In each case, we can write the molar Gibbs free energy of a substance J as

$$G_m(J) = G_m°(J) + RT\ln a_J \qquad \textbf{(4b)*}$$

with the activity defined as in Section 10.2. For a gas that behaves ideally, Eq. 4b is the same as Eq. 4a. For a solute in an ideal solution, $a_J = [J]/c°$ and Eq. 4b becomes

$$G_m(J) = G_m°(J) + RT\ln([J]/c°) \qquad \textbf{(4c)}$$

Note that $G_m(J)$ has its standard value, $G_m°(J)$, when $[J] = 1\ \text{mol·L}^{-1}$. For a pure solid or liquid $a_J = 1$, so

$$G_m(J) = G_m°(J) \qquad \textbf{(4d)}$$

That is, for a pure solid or liquid, the molar Gibbs free energy always has its standard value (provided the pressure is 1 bar).

We are now ready to find the value of ΔG at any stage of a reaction from the composition of the reaction mixture at that point.

HOW DO WE DO THAT?

To keep the units straight, we need to use the "molar" convention for this calculation (in which the n are pure numbers and we write the subscript r on ΔG) and to use the stoichiometric coefficients in reaction E as pure numbers. To find an expression for ΔG_r, we substitute Eq. 4 for each substance into Eq. 3a. For example, for the general reaction E,

$$\begin{aligned}\Delta G_r &= \{cG_m(C) + dG_m(D)\} - \{aG_m(A) + bG_m(B)\}\\ &= \{c[G_m°(C) + RT\ln a_C] + d[G_m°(D) + RT\ln a_D]\}\\ &\qquad - \{a[G_m°(A) + RT\ln a_A] + b[G_m°(B) + RT\ln a_B]\}\\ &= \{cG_m°(C) + dG_m°(D)\} - \{aG_m°(A) + bG_m°(B)\}\\ &\qquad + RT\{(c\ln a_C + d\ln a_D) - (a\ln a_A + b\ln a_B)\}\end{aligned}$$

Notice that the combination of the first four terms in the final equation is the standard Gibbs free energy of reaction, $\Delta G_r°$ (Eq. 19 of Chapter 8):

$$\Delta G_r° = \{cG_m°(C) + dG_m°(D)\} - \{aG_m°(A) + bG_m°(B)\}$$

Therefore,

$$\Delta G_r = \Delta G_r° + RT\{(c\ln a_C + d\ln a_D) - (a\ln a_A + b\ln a_B)\}$$

We can also tidy up the four logarithmic terms:

From $s \ln x = \ln x^s$, $(c \ln a_C + d \ln a_D) - (a \ln a_A + b \ln a_B) = (\ln a_C{}^c + \ln a_D{}^d) - (\ln a_A{}^a + \ln a_B{}^b)$

From $\ln x + \ln y = \ln xy$, $(\ln a_C{}^c + \ln a_D{}^d) - (\ln a_A{}^a + \ln a_B{}^b) = \ln a_C{}^c a_D{}^d - \ln a_A{}^a a_B{}^b$

From $\ln x - \ln y = \ln (x/y)$, $\ln a_C{}^c a_D{}^d - \ln a_A{}^a a_B{}^b = \ln (a_C{}^c a_D{}^d / a_A{}^a a_B{}^b)$

Overall, therefore,

$$(c \ln a_C + d \ln a_D) - (a \ln a_A + b \ln a_B) = \ln \frac{(a_C)^c (a_D)^d}{(a_A)^a (a_B)^b}$$

Now we can bring our work together and write:

$$\Delta G_r = \Delta G_r{}^\circ + RT \ln \frac{(a_C)^c (a_D)^d}{(a_A)^a (a_B)^b}$$

A note on good practice: Notice that by using the "molar" convention, the units match: RT is a molar energy (in joules per mole), and so too are the two Gibbs free energy terms. You should always use the molar convention when RT appears in an equation but is not multiplied by an amount in moles.

The expression that we have just derived may be written

$$\Delta G_r = \Delta G_r{}^\circ + RT \ln Q \qquad (5)^*$$

with the **reaction quotient** Q defined as

$$Q = \frac{(a_C)^c (a_D)^d}{(a_A)^a (a_B)^b} \qquad (6)$$

Equation 5 shows how the Gibbs free energy of reaction varies with the activities (the partial pressures of gases or molarities of solutes) of the reactants and products. The expression for Q has the same form as the expression for K, but the activities refer to *any* stage of the reaction.

EXAMPLE 10.2 Calculating the Gibbs free energy of reaction from the reaction quotient

The standard Gibbs free energy of reaction for $2\,SO_2(g) + O_2(g) \longrightarrow 2\,SO_3(g)$ is $\Delta G_r{}^\circ = -141.74\ kJ\cdot mol^{-1}$ at 25.00°C. (a) What is the Gibbs free energy of reaction when the partial pressure of each gas is 100. bar? (b) What is the spontaneous direction of the reaction under these conditions?

PLAN Calculate the reaction quotient and substitute it and the standard Gibbs free energy of reaction into Eq. 5. If $\Delta G_r < 0$, the forward reaction is spontaneous at the given composition. If $\Delta G_r > 0$, the reverse reaction is spontaneous at the given composition. If $\Delta G_r = 0$, there is no tendency to react in either direction; the reaction is at equilibrium. At 298.15 K, $RT = 2.479\ kJ\cdot mol^{-1}$.

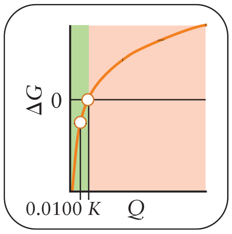
SOLVE

(a) From $Q = (a_{SO_3})^2/(a_{SO_2})^2(a_{O_2}) = (P_{SO_3})^2/(P_{O_2})^2(P_{O_2})$,

$$Q = \frac{(100.)^2}{(100.)^2 \times (100.)} = 1.00 \times 10^{-2}$$

From $\Delta G_r = \Delta G_r° + RT \ln Q$,

$$\Delta G_r = -141.74 \text{ kJ·mol}^{-1} + (2.479 \text{ kJ·mol}^{-1}) \ln (1.00 \times 10^{-2})$$
$$= -153.16 \text{ kJ·mol}^{-1}$$



(b) Because the Gibbs free energy of reaction is negative, the formation of products is spontaneous (as indicated by the green region in the diagram) at this composition and temperature.

Self-Test 10.4A The standard Gibbs free energy of reaction for $H_2(g) + I_2(g) \longrightarrow 2\,HI(g)$ is $\Delta G_r° = -21.1$ kJ·mol^{-1} at 500. K (at which temperature $RT = 4.16$ kJ·mol^{-1}). What is the value of ΔG_r at 500. K when the partial pressures of the gases are $P_{H_2} = 1.5$ bar, $P_{I_2} = 0.88$ bar, and $P_{HI} = 0.065$ bar? What is the spontaneous direction of the reaction?

[***Answer:*** -45 kJ·mol^{-1}; toward products]

Self-Test 10.4B The standard Gibbs free energy of reaction for $N_2O_4(g) \longrightarrow 2\,NO_2(g)$ is $\Delta G_r° = +4.73$ kJ·mol^{-1} at 298 K. What is the value of ΔG_r when the partial pressures of the gases are $P_{N_2O_4} = 0.80$ bar and $P_{NO_2} = 2.10$ bar? What is the spontaneous direction of the reaction?

Now we come to the most important point in this chapter. At equilibrium, the activities (the partial pressures or molarities) of all the substances taking part in the reaction have their equilibrium values. At this point the expression for Q (in which the activities have their equilibrium values) has become the equilibrium constant, K, of the reaction. That is,

$$\text{At equilibrium,} \qquad Q = K \qquad (7)$$

Thermodynamics has explained the puzzling form of K: it is a direct consequence of Eq. 4b, which shows how the Gibbs free energy of a substance depends on its activity, and is simply the value of Q when all the species have their equilibrium values.

We can now take another important step. We know that at equilibrium $\Delta G_r = 0$ and have just seen that at equilibrium $Q = K$. It follows from Eq. 5 that, at equilibrium,

$$0 = \Delta G_r° + RT \ln K$$

and therefore that

$$\Delta G_r° = -RT \ln K \qquad (8)^*$$

This fundamentally important equation links thermodynamic quantities—which are widely available from tables of thermodynamic data—and the composition of a system at equilibrium. Note that:

- If $\Delta G_r°$ is negative, then $\ln K$ must be positive and therefore $K > 1$; products are favored at equilibrium.
- If $\Delta G_r°$ is positive, then $\ln K$ must be negative and therefore $K < 1$; reactants are favored at equilibrium.

A note on good practice: Always write Eq. 8 with the standard state symbol. Note too that, for the units to match on both sides (joules per mole), and as signaled by the presence of RT not multiplied by an amount in moles, we have to use the "molar" convention for the standard Gibbs free energy.

EXAMPLE 10.3 **Predicting the value of K from the standard Gibbs free energy of reaction**

At 25.00°C, the standard Gibbs free energy of reaction for $\frac{1}{2}$ $H_2(g)$ + $\frac{1}{2}$ $I_2(s) \longrightarrow HI(g)$ is $+1.70\ kJ \cdot mol^{-1}$; calculate the equilibrium constant for this reaction.

Anticipate Because the standard Gibbs free energy of the reaction is positive, we should expect the equilibrium constant to be less than 1.

PLAN Use Eq. 8, with the temperature in kelvins.

SOLVE

From $\Delta G_r° = -RT \ln K$ in the form $\ln K = -\Delta G_r°/RT$, first converting the units of $\Delta G_r°$ to joules per mole and temperature to kelvins,

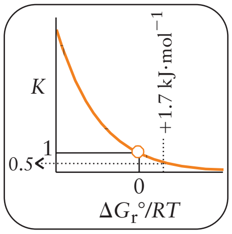
$$\ln K = -\frac{1.70 \times 10^3\ J \cdot mol^{-1}}{(8.3145\ J \cdot K^{-1} mol^{-1}) \times (298.15\ K)}$$

$$= -\frac{1.70 \times 10^3}{8.3145 \times 298.15}$$

$$= -0.685$$

Take the inverse logarithm ($e^{\ln x} = x$)

$$K = 0.50$$



Evaluate As expected, the equilibrium constant is less than one.

A note on good practice: Exponential functions (inverse logarithms, e^x) are very sensitive to the value of x, so carry out all the arithmetic in one step to avoid rounding errors.

Self-Test 10.5A Use the thermodynamic data in Appendix 2A to calculate K from the value of $\Delta G_r°$ for the reaction $N_2O_4(g) \longrightarrow 2\ NO_2(g)$ at 298 K.

[***Answer:*** $K = 0.15$]

Self-Test 10.5B Use the thermodynamic data in Appendix 2A to calculate K from the value of $\Delta G_r°$ for the reaction $2\ NO(g) + O_2(g) \longrightarrow 2\ NO_2(g)$ at 298 K.

We can now begin to acquire some insight into why some reactions have large equilibrium constants and others have small ones. It follows from $\Delta G_r° = \Delta H_r° - T\Delta S_r°$ and $\Delta G_r° = -RT \ln K$ that

$$\ln K = -\frac{\Delta G_r°}{RT} = -\frac{\Delta H_r°}{RT} + \frac{\Delta S_r°}{R}$$

When we take inverse logarithms of both sides and use $e^{x+y} = e^x e^y$, we obtain

$$K = e^{-\Delta H_r°/RT + \Delta S_r°/R} = e^{-\Delta H_r°/RT} e^{\Delta S_r°/R} \quad (9)$$

We see that K can be expected to be small if $\Delta H_r°$ is positive. An endothermic reaction is therefore likely to have $K < 1$ and is unlikely to form much product. Only if $\Delta S_r°$ is large and positive can we expect $K > 1$ for an endothermic reaction. Conversely, if a reaction is strongly exothermic, then $\Delta H_r°$ is large and negative. Now we can expect $K > 1$ and the products to be favored. In other words, we can expect strongly exothermic reactions to go to completion.

The reaction quotient, Q, has the same form as K, the equilibrium constant, except that Q uses the activities evaluated at an arbitrary stage of the reaction. The equilibrium constant is related to the standard Gibbs free energy of reaction by $\Delta G_r° = -RT \ln K$.

10.4 The Extent of Reaction

When $\Delta G_r°$ for a reaction is strongly negative, the reaction goes nearly to completion before it reaches equilibrium and the equilibrium reaction mixture consists mainly of products. Because the concentrations or partial pressures of products appear in the numerator of K and those of reactants in the denominator, the numerator will be large and the denominator small. Therefore, the value of K is large. In contrast, when $\Delta G_r°$ for a reaction is strongly positive, equilibrium is reached after very little reaction has taken place, the numerator is small and the denominator large; therefore, K is small.

For instance, consider the reaction

$$H_2(g) + Cl_2(g) \rightleftharpoons 2\,HCl(g) \qquad K = \frac{(P_{HCl})^2}{P_{H_2}P_{Cl_2}}$$

Experiment shows that $K = 4.0 \times 10^{18}$ at 500. K. Such a large value for K tells us that the system reaches equilibrium only when most of the reactants have been converted into HCl. In fact, this reaction essentially goes to completion. Now consider the equilibrium

$$N_2(g) + O_2(g) \rightleftharpoons 2\,NO(g) \qquad K = \frac{(P_{NO})^2}{P_{N_2}P_{O_2}}$$

Experiment gives $K = 3.4 \times 10^{-21}$ at 800. K. The very small value of K tells us that equilibrium is reached when only a small amount of product has formed. The reactants N_2 and O_2 are the dominant species in the system at equilibrium.

We can summarize these remarks as follows for chemical equations written with the smallest whole-number stoichiometric coefficients (Fig. 10.5):

- Large values of K (larger than about 10^3): the equilibrium favors the products.
- Intermediate values of K (approximately in the range 10^{-3} to 10^3): neither reactants nor products are strongly favored at equilibrium.
- Small values of K (smaller than about 10^{-3}): the equilibrium favors the reactants.

The following example shows how to use the equilibrium constant to calculate an equilibrium concentration.

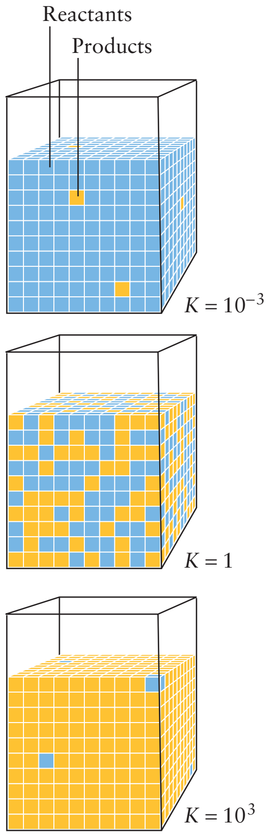


FIGURE 10.5 The size of the equilibrium constant indicates whether the reactants or the products are favored. In this diagram, the reactants are represented by blue cubes and the products by yellow cubes. Note that reactants are favored when K is small (top), products are favored when K is large (bottom), and reactants and products are in equal abundance when $K = 1$.

Because equilibrium constants must be raised to a power when a chemical equation is multiplied by a factor, and therefore change in magnitude, these rules are only general guidelines.

EXAMPLE 10.4 Calculating an equilibrium composition

Suppose that, in an equilibrium mixture of HCl, Cl_2, and H_2, the partial pressure of H_2 is 4.2 mPa and that of Cl_2 is 8.3 mPa. What is the partial pressure of HCl at 500. K, given $K = 4.0 \times 10^{18}$ for $H_2(g) + Cl_2(g) \rightleftharpoons 2\,HCl(g)$?

Anticipate Because the equilibrium constant is large, we should expect a high equilibrium partial pressure for the product, HCl.

PLAN At equilibrium, the partial pressures of the reactants and products (in bar, 1 bar = 10^5 Pa) satisfy the expression for K. Therefore, rearrange the expression to give the one unknown concentration, and substitute the data.

SOLVE First convert the units of partial pressures to bars using 1 bar = 10^5 Pa: $P_{H_2} = 4.2 \times 10^{-8}$ bar, $P_{Cl_2} = 8.3 \times 10^{-8}$ bar. Write the expression for the equilibrium constant from the chemical equation given.

From $K = (P_{HCl})^2/P_{H_2}P_{Cl_2}$ in the form $P_{HCl} = (KP_{H_2}P_{Cl_2})^{1/2}$,

$$P_{HCl} = \{(4.0 \times 10^{18}) \times (4.2 \times 10^{-8}) \times (8.3 \times 10^{-8})\}^{1/2} = 1.2 \times 10^2$$

Evaluate As expected, at equilibrium, the partial pressure of product in the system, 120 bar, is overwhelming relative to the tiny partial pressures of the reactants.

Self-Test 10.6A Suppose that the equilibrium partial pressures of H_2 and Cl_2 are both 1.0 μPa. What is the equilibrium partial pressure of HCl at 500. K, given $K = 4.0 \times 10^{18}$?

[***Answer:*** P_{HCl} = 20. mbar]

Self-Test 10.6B Suppose that the equilibrium partial pressures of N_2 and O_2 in the reaction $N_2(g) + O_2(g) \rightleftharpoons 2\,NO(g)$ at 800. K are both 52 kPa. What is the partial pressure (in pascals) of NO at equilibrium if $K = 3.4 \times 10^{-21}$ at 800. K?

If K is large, products are favored at equilibrium (the equilibrium "lies to the right"); if K is small, reactants are favored (the equilibrium "lies to the left").

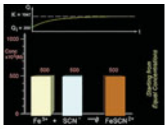
10.5 The Direction of Reaction

Now suppose that the system treated in Example 10.4 is not at equilibrium. For example, we may be given the concentrations of reactants and products for some arbitrary stage of a reaction. Can we tell whether it is at equilibrium or whether it has a tendency to form more products or to decompose into reactants? To answer this question, we first need the equilibrium constant. We may have to determine it experimentally or calculate it from standard Gibbs free energy data. Then we calculate the reaction quotient, Q, from the actual composition of the reaction mixture, as described in Section 10.3. To predict whether that mixture of reactants and products will tend to produce more products or more reactants, we compare Q with K:

- If $Q < K$, ΔG is negative; the concentrations or partial pressures of the products are too low relative to those of the reactants for equilibrium. Hence, the reaction has a tendency to proceed toward products.
- If $Q = K$, ΔG is zero; the mixture has its equilibrium composition and has no tendency to change in either direction.
- If $Q > K$, ΔG is positive; the reverse reaction is spontaneous and the products tend to decompose into the reactants.

This pattern is summarized in Fig. 10.6.

The same pattern is seen when we plot the Gibbs free energy of a reaction mixture against its changing composition, as we did in Fig. 10.4. Reaction tends to proceed toward the composition at the lowest point of the curve, because that is the direction of decreasing Gibbs free energy. The composition at the lowest point of the curve—the point of minimum Gibbs free energy—corresponds to equilibrium. For a system at equilibrium, any change would lead to a reaction mixture with a greater Gibbs free energy, and so neither the forward nor the reverse reaction is spontaneous. When the minimum value of the Gibbs free energy lies very close to pure products, the equilibrium composition strongly favors products and "goes to completion" (Fig. 10.7a). When the Gibbs free energy minimum lies very close to the pure reactants, the equilibrium composition strongly favors the reactants and the reaction "does not go" (Fig. 10.7b).



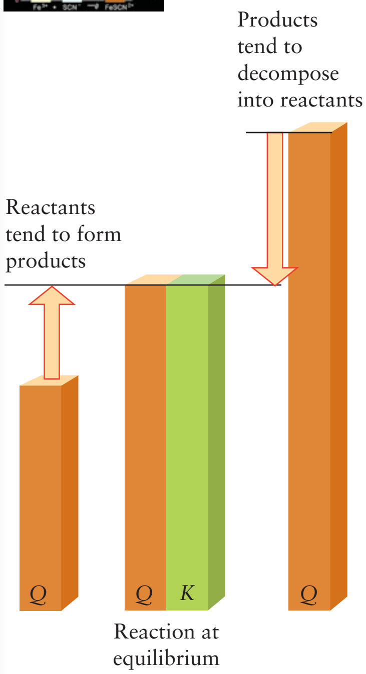


FIGURE 10.6 The relative sizes of the reaction quotient Q and the equilibrium constant K indicate the direction in which a reaction mixture tends to change. The arrows show that when $Q < K$, reactants form products (left) and when $Q > K$, products form reactants (right). There is no tendency to change once the reaction quotient has become equal to the equilibrium constant.

Animation 10.6

A note on good practice: Whether or not a reaction is spontaneous depends on the composition, so it is better to say that $K > 1$ for a reaction with a negative $\Delta G_r°$ rather than that it is spontaneous. However, for reactions with very large equilibrium constants, it is very unlikely that the mixture of reagents prepared in the laboratory will correspond to $Q > K$, and it is common to refer to such reactions as "spontaneous."

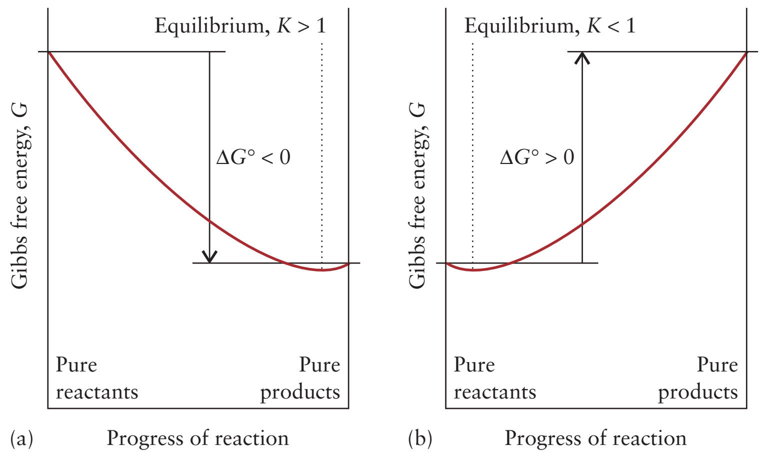

FIGURE 10.7 (a) A reaction that has the potential to go to completion ($K > 1$) is one in which the minimum of the free-energy curve (the position of equilibrium) lies close to pure products. (b) A reaction that has little tendency to form products ($K < 1$) is one in which the minimum of the free-energy curve lies close to pure reactants.

EXAMPLE 10.5 Predicting the direction of reaction

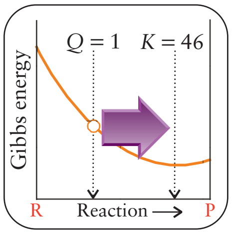
A mixture of hydrogen, iodine, and hydrogen iodide, each at 55 kPa, was introduced into a container heated to 783 K. At this temperature, $K = 46$ for $H_2(g) + I_2(g) \rightleftharpoons 2\,HI(g)$. Predict whether HI has a tendency to form or to decompose into $H_2(g)$ and $I_2(g)$.

PLAN If $Q > K$, the products need to decompose into reactants until their concentrations match K. The opposite is true if $Q < K$: in that case, more products need to form. Therefore, we need to calculate Q and compare it with K.

SOLVE Substitute the data, noting that 55 kPa is equivalent to 0.55 bar, in the reaction quotient.

From $Q = (P_{HI})^2/P_{H_2}P_{I_2}$,

$$Q = \frac{(0.55)^2}{0.55 \times 0.55} = 1.0$$



Because $Q < K$, we conclude that the reaction will tend to form more product and consume reactants.

Self-Test 10.7A A mixture of H_2, N_2, and NH_3 with partial pressures 22 kPa, 44 kPa, and 18 kPa, respectively, was prepared and heated to 500. K, at which temperature $K = 3.6 \times 10^{-2}$ for reaction C. Decide whether ammonia tends to form or decompose.

[*Answer* $Q = 6.9$; tends to decompose]

Self-Test 10.7B For the reaction $N_2O_4(g) \rightleftharpoons 2\,NO_2(g)$ at 298 K, $K = 0.15$. A mixture of N_2O_4 and NO_2 with initial partial pressures of 2.4 and 1.2 bar, respectively, was prepared at 298 K. Which compound will tend to increase its partial pressure?

A reaction has a tendency to form products if $Q < K$ and to form reactants if $Q > K$.

EQUILIBRIUM CALCULATIONS

We have seen that the value of an equilibrium constant tells us whether we can expect a high or low concentration of product at equilibrium. The constant also allows us to predict the spontaneous direction of reaction in a reaction mixture of any composition. In the following three sections, we see how to express the equilibrium constant in terms of molar concentrations of gases as well as partial pressures and how to predict the equilibrium

composition of a reaction mixture, given the value of the equilibrium constant for the reaction. Such information is critical to the success of many industrial processes and is fundamental to the discussion of acids and bases in the following chapters.

10.6 The Equilibrium Constant in Terms of Molar Concentrations of Gases

The equilibrium constant in Eq. 2 is defined in terms of activities, and the activities are interpreted in terms of the partial pressures or concentrations. Gases *always* appear in K as the numerical values of their partial pressures in bar and solutes always appear as the numerical values of their molarities. Often, however, in areas such as kinetics and atmospheric chemistry, we want to discuss gas-phase equilibria in terms of molar concentrations (the amount of gas molecules in moles divided by the volume of the container, $[J] = n_J/V$), not partial pressures. To do so, we introduce the equilibrium constant K_c, which for reaction E is defined as

$$K_c = \frac{[C]^c[D]^d}{[A]^a[B]^b} \tag{10}$$

with each molar concentration raised to a power equal to the stoichiometric coefficient of the species in the chemical equation. As usual, we have replaced $[J]/c°$ by $[J]$ itself, which represents the numerical value of the molar concentration of the gas J. For example, for the ammonia synthesis equilibrium, reaction C,

$$K_c = \frac{[NH_3]^2}{[N_2][H_2]^3} \tag{11}$$

We are free to choose either K or K_c to report the equilibrium constant of a reaction. However, it is important to remember that calculations of an equilibrium constant from thermodynamic tables of data (standard Gibbs free energies of formation, for instance) and Eq. 8 give K, not K_c. In some cases, we need to know K_c after we have calculated K from thermodynamic data, and so we need to be able to convert between these two constants.

HOW DO WE DO THAT?

The overall strategy for finding the relation between K and K_c is to replace the partial pressures that appear in K by the molar concentrations and thereby generate K_c. For this calculation, we write activities as $P_J/P°$ and $[J]/c°$ and keep track of the units by keeping $P°$ and $c°$ in our expressions.

Our starting point is Eq. 1b in its complete form:

$$K = \frac{(P_C/P°)^c(P_D/P°)^d}{(P_A/P°)^a(P_B/P°)^b} = \frac{(P°)^{a+b}(P_C)^c(P_D)^d}{(P°)^{c+d}(P_A)^a(P_B)^b} = (P°)^{a+b-(c+d)}\frac{(P_C)^c(P_D)^d}{(P_A)^a(P_B)^b}$$

The molar concentration of a gas J is $[J] = n_J/V$. We assume ideal gas behavior and write the ideal gas law $P_JV = n_JRT$ as

$$P_J = \frac{n_JRT}{V} = RT\frac{n_J}{V} = RT[J]$$

When this expression is substituted for each gas in the expression for K, we obtain

$$\frac{(P_C)^c(P_D)^d}{(P_A)^a(P_B)^b} = \frac{(RT[C])^c(RT[D])^d}{(RT[A])^a(RT[B])^b} = (RT)^{c+d-(a+b)}\frac{[C]^c[D]^d}{[A]^a[B]^b}$$

At this point we recognize that K_c, Eq. 10, in its complete form can be written as follows:

$$K_c = \frac{([C]/c°)^c([D]/c°)^d}{([A]/c°)^a([B]/c°)^b} = \frac{(c°)^{a+b}[C]^c[D]^d}{(c°)^{c+d}[A]^a[B]^b} = (c°)^{a+b-(c+d)}\frac{[C]^c[D]^d}{[A]^a[B]^b}$$

and therefore

$$\frac{[C]^c[D]^d}{[A]^a[B]^b} = \frac{K_c}{(c°)^{a+b-(c+d)}}$$

When we substitute this expression into the equation for the ratio of partial pressures we obtain

$$\frac{(P_C)^c(P_D)^d}{(P_A)^a(P_B)^b} = (RT)^{c+d-(a+b)}\frac{K_c}{(c°)^{a+b-(c+d)}} = (c°RT)^{c+d-(a+b)}K_c$$

We conclude that

$$K = (P°)^{a+b-(c+d)}(c°RT)^{c+d-(a+b)}K_c = \left(\frac{c°RT}{P°}\right)^{c+d-(a+b)}K_c$$

A useful way to remember the general form of the expression that we have derived is to write it as

$$K = \left(\frac{c°RT}{P°}\right)^{\Delta n}K_c \qquad \textbf{(12a)*}$$

where Δn is the difference of stoichiometric coefficients for gas-phase species in the chemical equation, calculated as $\Delta n = n_{\text{products}} - n_{\text{reactants}}$ (so $\Delta n = 2 - (1 + 3) = -2$ for reaction C). If no gases take part in the reaction or if $\Delta n = 0$, then $K = K_c$. The same relation holds between Q and Q_c, the reaction quotient in terms of concentrations. Equation 12a is commonly written more succinctly as

$$K = (RT)^{\Delta n}K_c \qquad \textbf{(12b)}$$

but the full version clarifies the units and should be used in calculations. Some values of K_c are listed in Table 10.2.

Thinking point: Suppose the gases involved in a reaction behave as real gases with significant intermolecular attractions. Would the value of K_c calculated from Eq. 12 be too high, too low, or the same as the actual value?

EXAMPLE 10.6 Converting between K and K_c

At 400.°C, the equilibrium constant K for $2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$ is 3.1×10^4. What is the value of K_c at this temperature?

PLAN Because $P° = 1$ bar and $c° = 1\ mol{\cdot}L^{-1}$, it is sensible to use R expressed in bars and liters, $R = 8.3145 \times 10^{-2}\ L{\cdot}bar{\cdot}K^{-1}{\cdot}mol^{-1}$, and to note that

$$\frac{P°}{Rc°} = \frac{1\ \text{bar}}{(8.3145\ \text{L·bar·K}^{-1}\text{mol}^{-1}) \times (1\ \text{mol·L}^{-1})} = 12.03\ \text{K}$$

Then, Eq. 12a can be written as

$$K = \left(\frac{T}{12.03\ \text{K}}\right)^{\Delta n}K_c$$

To use this equation, identify the value of Δn for the reaction, convert the temperature to the Kelvin scale, and rearrange it to solve for K_c.

What should we assume? That the gases are ideal.

SOLVE

From the chemical equation,

$$\Delta n = 2 - (2 + 1) = -1 \text{ and } T = 400. + 273.15\ \text{K} = 673\ \text{K}$$

From $K = (T/12.03\ \text{K})^{\Delta n}K_c$ in the form $K_c = (T/12.03\ \text{K})^{-\Delta n}K$,

$$K_c = \left(\frac{673\ \text{K}}{12.03\ \text{K}}\right) \times (3.1 \times 10^4) = 1.7 \times 10^6$$

Self-Test 10.8A The equilibrium constant for the ammonia synthesis (reaction C) is $K = 41$ at 127°C. What is the value of K_c at that temperature?

[***Answer:*** $\Delta n = -2$; so $K_c = 4.5 \times 10^4$]

Self-Test 10.8B At 127°C, the equilibrium constant for $N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$ is $K = 47.9$. What is the value of K_c at that temperature?

For thermodynamic calculations, gas-phase equilibria are expressed in terms of K but, for practical calculations, they may be expressed in terms of molar concentrations by using Eq. 12.

10.7 Alternative Forms of the Equilibrium Constant

The powers to which the activities are raised in the expression for an equilibrium constant must match the stoichiometric coefficients in the chemical equation, which is normally written with the smallest whole numbers for coefficients. Therefore, if we change the stoichiometric coefficients in a chemical equation (for instance, by multiplying through by a factor), then we must make sure that the equilibrium constant corresponds to that change. For example, at 700 K,

$$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g) \qquad K_{c1} = \frac{[HI]^2}{[H_2][I_2]} = 54$$

If we rewrite the chemical equation by multiplying through by 2, the equilibrium constant becomes

$$2\ H_2(g) + 2\ I_2(g) \rightleftharpoons 4\ HI(g) \qquad K_{c2} = \frac{[HI]^4}{[H_2]^2[I_2]^2} = (54)^2 = 2.9 \times 10^3$$

In general:

- If we multiply a chemical equation by a factor n, we raise K (and K_c) to the nth power.

Now suppose we reverse the original equation for the reaction:

$$2\ HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

This equation still describes the same equilibrium; but we write the equilibrium constant for this equation as

$$K_{c3} = \frac{[H_2][I_2]}{[HI]^2} = \frac{1}{K_{c1}} = \frac{1}{54} = 0.019$$

In general:

- The equilibrium constant for an equilibrium written in one direction is the reciprocal of the equilibrium constant for the equilibrium written in the opposite direction.

A note on good practice: As these examples have shown, it is important to specify the chemical equation to which the equilibrium constant applies.

If a chemical equation can be expressed as the sum of two or more chemical equations,

- The equilibrium constant for the overall reaction is the product of the equilibrium constants for the component reactions.

For example, consider the three gas-phase reactions

$$2\ P(g) + 3\ Cl_2(g) \rightleftharpoons 2\ PCl_3(g) \qquad K_1 = \frac{(P_{PCl_3})^2}{(P_P)^2(P_{Cl_2})^3}$$

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g) \qquad K_2 = \frac{P_{PCl_5}}{P_{PCl_3}P_{Cl_2}}$$

$$2\ P(g) + 5\ Cl_2(g) \rightleftharpoons 2\ PCl_5(g) \qquad K_3 = \frac{(P_{PCl_5})^2}{(P_P)^2(P_{Cl_2})^5}$$

The third reaction is the following sum of the first two reactions (notice that we multiplied the second one by a factor of 2):

$$2\ P(g) + 3\ Cl_2(g) \rightleftharpoons 2\ PCl_3(g)$$
$$2\ PCl_3(g) + 2\ Cl_2(g) \rightleftharpoons 2\ PCl_5(g)$$
$$\overline{2\ P(g) + 5\ Cl_2(g) \rightleftharpoons 2\ PCl_5(g)}$$

and the equilibrium constant, K_3, of the overall reaction can be written

$$K_3 = \frac{(P_{PCl_5})^2}{(P_P)^2(P_{Cl_2})^5} = \overbrace{\frac{(P_{PCl_3})^2}{(P_P)^2(P_{Cl_2})^3}}^{K_1} \times \overbrace{\frac{(P_{PCl_5})^2}{(P_{PCl_3})^2(P_{Cl_2})^2}}^{K_2{}^2} = K_1K_2{}^2$$

Notice that, because we multiplied the second reaction by two to obtain the sum, its equilibrium constant has been raised to the second power.

Self-Test 10.9A At 500. K, K for $H_2(g) + D_2(g) \rightleftharpoons 2\ HD(g)$ is 3.6. What is the value of K for $4\ HD(g) \rightleftharpoons 2\ H_2(g) + 2\ D_2(g)$?

[***Answer:*** 0.077]

Self-Test 10.9B At 500. K, K_c for $F_2(g) \rightleftharpoons 2\ F(g)$ is 7.3×10^{-13}. What is the value of K_c for $\frac{1}{2}\ F_2(g) \rightleftharpoons F(g)$?

Table 10.3 summarizes the relations between equilibrium constants for the same reaction written in different ways.

TABLE 10.3 Relations Between Equilibrium Constants*

Chemical equation	Equilibrium constant
$a\ A + b\ B \rightleftharpoons c\ C + d\ D$	K_1
$c\ C + d\ D \rightleftharpoons a\ A + b\ B$	$K_2 = 1/K_1 = K_1{}^{-1}$
$na\ A + nb\ B \rightleftharpoons nc\ C + nd\ D$	$K_3 = K_1{}^n$

*For a reaction that can be expressed as the sum of other reactions, the equilibrium constant is the product of the equilibrium constants of the component reactions

10.8 Using Equilibrium Constants

The equilibrium constant of a reaction contains information about the equilibrium composition at the given temperature. However, in many cases, we know only the initial composition of the reaction mixture and are given apparently incomplete information about the equilibrium composition. In fact, the missing information can usually be inferred by using the reaction stoichiometry. The easiest way to proceed is to draw up an **equilibrium table,** a table showing the initial composition, the changes needed to reach equilibrium in terms of some unknown quantity x, and the final equilibrium composition. The procedure is summarized in Toolbox 10.1 and illustrated in the examples that follow.

TOOLBOX 10.1 HOW TO SET UP AND USE AN EQUILIBRIUM TABLE

CONCEPTUAL BASIS

The composition of a reaction mixture tends to adjust until the molar concentrations or partial pressures of gases ensure that $Q_c = K_c$ and $Q = K$. A change in the abundance of any one component is linked to changes in the others by the reaction stoichiometry.

PROCEDURE

Step 1 Write the equilibrium constant for the balanced chemical equation (the equation must be given, because the stoichiometric coefficients are needed to write K). Then set up an equilibrium table as shown here, with columns labeled by the species taking part in the reaction. In the first row, show the initial composition (molar concentration or partial pressure) of each species, but ignore pure liquids and solids.

	Species 1	Species 2	Species 3	. . .
Initial composition				. . .
Change in composition				. . .
Final composition				. . .

The first line in the table shows how the reaction system was prepared before reaction began. As always, use molar concentrations (in moles per liter) and partial pressures (in bars) but strike out the units. Omit pure solids and liquids.

Step 2 In the second row, write the changes in the composition that are needed for the reaction to reach equilibrium.

When we do not know the changes, write one of them as x or a multiple of x and then use the stoichiometry of the balanced equation to express the other changes in terms of that x.

Step 3 In the third row, write the equilibrium compositions in terms of x by adding the change in composition (from step 2) to the initial value for each substance (from step 1).

Although a change in composition may be positive (an increase) or negative (a decrease), the value of each concentration or partial pressure itself must be positive.

Step 4 Use the equilibrium constant to determine the value of x, the unknown change in molar concentration or partial pressure.

A note on good practice: A good habit to adopt is to check the answer by substituting the equilibrium composition into the expression for K.

An approximation technique can greatly simplify calculations when the change in composition (x) is less than about 5% of the initial value. To use it, assume that x is negligible when added to or subtracted from a number. Thus, we can replace all expressions like $A + x$ or $A - 2x$, by A. When x occurs on its own (not added to or subtracted from another number), it is left unchanged. So, an expression such as $(0.1 - 2x)^2x$ simplifies to $(0.1)^2x$, provided that $2x \ll 0.1$ (specifically, if $2x < 0.005$). At the end of the calculation, it is important to verify that the calculated value of x is indeed smaller than 5% of the initial values. If it is not, then we must solve the equation without making an approximation.

The approximation procedure is illustrated in Example 10.7.

In some cases, the full equation for x is a quadratic equation of the form

$$ax^2 + bx + c = 0$$

When the approximation procedure is invalid, we use the exact solutions of this equation, which are

$$x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}$$

We have to decide which of the two solutions given by this expression is valid (the one with the + sign or the one with the – sign in front of the square root) by seeing which solution is chemically possible.

See Example 10.8 for an illustration of this procedure.

For some reactions, the equation for x in terms of K may be a higher-order polynomial. If an approximation is not valid, one approach to solving the equation is to use a graphing calculator or mathematical software to find the roots of the equation. The web site for this textbook has tools that can be used to solve such equations.

EXAMPLE 10.7 **Calculating the equilibrium composition by approximation**

Under certain conditions, nitrogen and oxygen react to form dinitrogen oxide, N_2O. Suppose that a mixture of 0.482 mol N_2 and 0.933 mol O_2 is transferred to a reaction vessel of volume 10.0 L and allowed to form N_2O at 800. K; at this temperature $K = 3.2 \times 10^{-28}$ for the reaction $2\,N_2(g) + O_2(g) \rightleftharpoons 2\,N_2O(g)$. Calculate the partial pressures of the gases in the equilibrium mixture.

Anticipate Because the equilibrium constant is so small, we should expect that equilibrium will be reached when only a very small amount of product has formed.

PLAN Use the procedure in Toolbox 10.1.

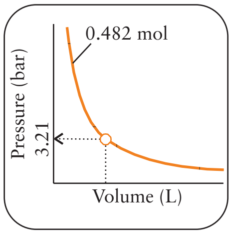
What should we assume? That the amount of product formed will be so small that the change in partial pressures of the reactants is negligible.

SOLVE The equilibrium constant for the reaction is $K = (P_{N_2O})^2/(P_{N_2})^2P_{O_2}$. The initial partial pressures are

From $P_J = n_JRT/V$,

$$P_{N_2} = \frac{(0.482\text{ mol}) \times (8.3145 \times 10^{-2}\text{ L·bar·K}^{-1}\text{mol}^{-1}) \times (800.\text{ K})}{10.0\text{ L}}$$

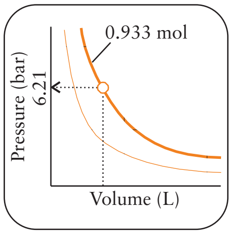
$= 3.21$ bar



From $P_J = n_JRT/V$,

$$P_{O_2} = \frac{(0.933\text{ mol}) \times (8.3145 \times 10^{-2}\text{ L·bar·K}^{-1}\text{mol}^{-1}) \times (800.\text{ K})}{10.0\text{ L}}$$

$= 6.21$ bar



and therefore

$$P_{N_2O} = 0$$

The stoichiometry of the reaction implies that, if the partial pressure of O_2 decreases by x, then the partial pressure of N_2 decreases by $2x$ and that of N_2O increases by $2x$. Because there is no N_2O present initially, the equilibrium table, with all partial pressures in bar, is

	N_2	O_2	N_2O
Step 1 Initial partial pressure	3.21	6.21	0
Step 2 Changes in partial pressure	$-2x$	$-x$	$+2x$
Step 3 Equilibrium partial pressure	$3.21 - 2x$	$6.21 - x$	$2x$
Step 4 From $K = (P_{N_2O})^2/(P_{N_2})^2(P_{O_2})$	$K = \dfrac{(2x)^2}{(3.21 - 2x)^2 \times (6.21 - x)}$		

When rearranged, this equation is a cubic equation (an equation in x^3), which can be solved with a graphing calculator or mathematical software. However, because K is very small, we suppose that x will turn out to be so small that we can use the approximation procedure:

Replace $3.21 - 2x$ by 3.21 and $6.21 - x$ by 6.21.

$$K \approx \frac{(2x)^2}{(3.21)^2 \times (6.21)}$$

Rearrange into an equation for x.

$$x \approx \left\{\frac{(3.21)^2 \times (6.21) \times K}{4}\right\}^{1/2}$$

Substitute the value of K.

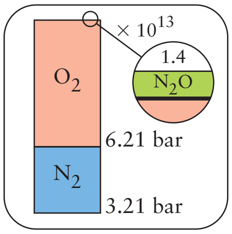
$$x \approx \left\{\frac{(3.21)^2 \times (6.21) \times (3.2 \times 10^{-28})}{4}\right\}^{1/2} = 7.2 \times 10^{-14}$$

The value of $2x$ is very small compared with 3.21 (far smaller than 5% of it), and so the approximation is valid. We conclude that, at equilibrium:

From $P_{N_2} = 3.21 - 2x$ bar, $P_{N_2} = 3.21$ bar

From $P_{O_2} = 6.21 - x$ bar, $P_{O_2} = 6.21$ bar

From $P_{N_2O} = 2x$ bar, $P_{N_2O} = 1.4 \times 10^{-13}$ bar



Evaluate As expected, very little product has formed. When substituted into the full expression for the equilibrium constant, these values give $K = 3.1 \times 10^{-28}$, in good agreement with the experimental value.

Self-Test 10.10A The initial partial pressures of nitrogen and hydrogen in a rigid, sealed vessel are 0.010 and 0.020 bar, respectively. The mixture is heated to a temperature at which $K = 0.11$ for $N_2(g) + 3\,H_2(g) \rightleftharpoons 2\,NH_3(g)$. What are the equilibrium partial pressures of each substance in the reaction mixture?

[***Answer:*** N_2: 0.010 bar; H_2: 0.020 bar; NH_3: 9.4×10^{-5} bar]

Self-Test 10.10B Hydrogen chloride gas is added to a reaction vessel containing solid iodine until its partial pressure reaches 0.012 bar. At the temperature of the experiment, $K = 3.5 \times 10^{-32}$ for $2\,HCl(g) + I_2(s) \rightleftharpoons 2\,HI(g) + Cl_2(g)$. Assume that some I_2 remains at equilibrium. What are the equilibrium partial pressures of each gaseous substance in the reaction mixture?

EXAMPLE 10.8 Calculating the equilibrium composition by using a quadratic equation

Suppose that we place 3.12 g of PCl_5 in a reaction vessel of volume 500. mL and allow the sample to reach equilibrium with its decomposition products phosphorus trichloride and chlorine at 250.°C, when $K = 78.3$ for the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$. All three substances are gases at 250°C. Find the composition of the equilibrium mixture in moles per liter.

Anticipate Because the equilibrium constant is neither very small nor very large, we should expect that the partial pressures of reactants and products at equilibrium will be similar to each other.

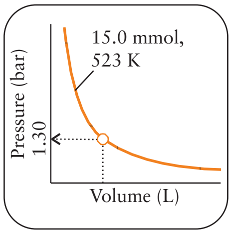
PLAN Use the general procedure set out in Toolbox 10.1.

SOLVE The equilibrium constant for the reaction is $K = P_{PCl_3}P_{Cl_2}/P_{PCl_5}$. First, we calculate the initial partial pressure of PCl_5 (the initial partial pressures of PCl_2 and Cl_2 are zero):

From $n_J = m_J/M_J$, the amount of PCl_5 added is:

$$n_{PCl_5} = \frac{3.12\ \text{g}}{208.24\ \text{g·mol}^{-1}} = \frac{3.12}{208.24}\ \text{mol}\ (=0.0150\ \text{mol})$$

From $P_J = n_JRT/V$, the initial partial pressure of PCl_5 is therefore



$$P_{PCl_5} = \left(\frac{3.12}{208.24}\ \text{mol}\right) \times \frac{(8.3145 \times 10^{-2}\ \text{L·bar·K}^{-1}\text{mol}^{-1}) \times (523\ \text{K})}{0.500\ \text{L}}$$
$$= 1.30\ \text{bar}$$

Use $P_{PCl_5} = 1.30$ in the expression for K and let the change in its partial pressure be $-x$. Construct the following table, with all partial pressures in bars.

	PCl_5	PCl_3	Cl_2
Step 1 Initial partial pressure	1.30	0	0
Step 2 Change in partial pressure	$-x$	$+x$	$+x$
Step 3 Equilibrium partial pressure	$1.30 - x$	x	x

From $K = P_{PCl_3}P_{Cl_2}/P_{PCl_5}$,

$$K = \frac{x^2}{1.30 - x}$$

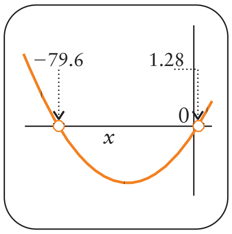
Rearrange the equation:

$$x^2 + Kx - 1.30K = 0$$

Substitute the value of K:

$$x^2 + 78.3x - 102 = 0$$

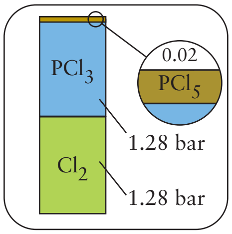
Solve for x by using the quadratic formula $x = \{-b \pm (b^2 - 4ac)^{1/2}\}/2a$.



$$x = \frac{-78.3 \pm \{(78.3)^2 - 4 \times (-102)\}^{1/2}}{2}$$
$$= -79.6 \text{ or } 1.28$$

Because the partial pressures must be positive and because x is the partial pressure of PCl_3, we select 1.28 as the solution. It follows that, at equilibrium:

From $P_{PCl_5} = 1.30 - x$ bar, $\quad P_{PCl_5} = 1.30 - 1.28$ bar $= 0.02$ bar
From $P_{PCl_3} = x$ bar, $\quad P_{PCl_3} = 1.28$ bar
From $P_{Cl_2} = x$ bar, $\quad P_{Cl_2} = 1.28$ bar



Evaluate As expected, the equilibrium concentrations of reactants and products have similar values. Figure 10.8 illustrates how the reaction approaches equilibrium.

Self-Test 10.11A Bromine monochloride, BrCl, decomposes into bromine and chlorine and reaches the equilibrium $2\,BrCl(g) \rightleftharpoons Br_2(g) + Cl_2(g)$, for which $K = 32$ at 500. K. If initially pure BrCl is present at a concentration of 3.30 mbar, what is its partial pressure in the mixture at equilibrium?

[***Answer:*** 0.3 mbar]

Self-Test 10.11B Chlorine and fluorine react at 2500. K to produce ClF and reach the equilibrium $Cl_2(g) + F_2(g) \rightleftharpoons 2\,ClF(g)$ with $K = 20$. If a gaseous mixture with $P_{Cl_2} = 0.200$ bar, $P_{F_2} = 0.100$ bar, and $P_{ClF} = 0.100$ bar is allowed to come to equilibrium at 2500. K, what is the partial pressure of ClF in the equilibrium mixture?

To calculate the equilibrium composition of a reaction mixture, set up an equilibrium table in terms of changes in the concentrations of reactants and products, express the equilibrium constant in terms of those changes, and solve the resulting equation.

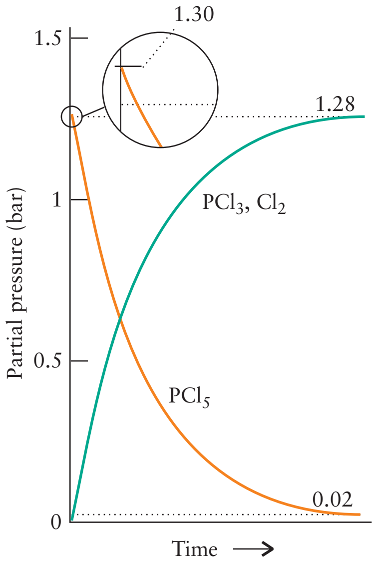


FIGURE 10.8 The approach of the composition of the reaction mixture to equilibrium when PCl_5 decomposes in a closed container. Note that the curves for Cl_2 and PCl_3 are superimposed, as they increase by the same amount.

THE RESPONSE OF EQUILIBRIA TO CHANGES IN CONDITIONS

Because chemical equilibria are dynamic, they respond to changes in the conditions under which a reaction is taking place. When we disturb an equilibrium by adding or removing a reactant, the value of ΔG is changed and the composition shifts until $\Delta G = 0$ again. The composition also might change in response to a change in pressure or temperature. In the following sections, we shall see how Haber used this responsiveness to control the equilibrium between ammonia, nitrogen, and hydrogen to increase the production of ammonia.

We can predict how the composition of a reaction mixture at equilibrium tends to change when the conditions are changed by following the general principle identified by the French chemist Henri Le Chatelier (Fig. 10.9):

> **Le Chatelier's principle:** When a stress is applied to a system in dynamic equilibrium, the equilibrium tends to adjust to minimize the effect of the stress.

This empirical principle is no more than a rule of thumb. It provides neither an explanation nor a quantitative prediction. However, we shall see that it is consistent with thermodynamics; and, as we develop it, we shall see the powerful *quantitative* conclusions that can be drawn from thermodynamics.

FIGURE 10.9 Henri Le Chatelier (1850–1936).

10.9 Adding and Removing Reagents

We start by considering changes in the composition of a system. Let's suppose that the ammonia synthesis reaction (reaction C) has reached equilibrium. Now suppose that we pump in more hydrogen gas. According to Le Chatelier's principle, the increase in the concentration of hydrogen molecules will tend to be minimized by the reaction of hydrogen with nitrogen. As a result, additional ammonia will be formed. If, instead of

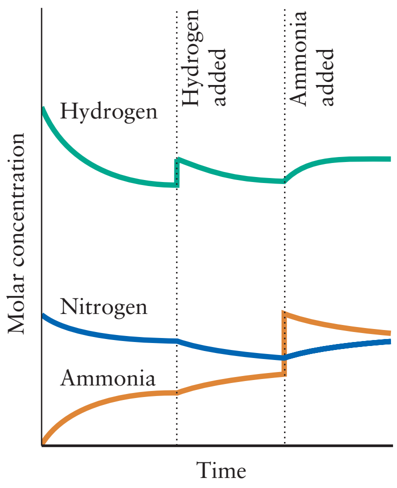

FIGURE 10.10 These graphs show the changes in composition that can be expected when additional hydrogen and then ammonia are added to an equilibrium mixture of nitrogen, hydrogen, and ammonia. Note that the addition of hydrogen results in the formation of ammonia, whereas the addition of ammonia results in the decomposition of some of the added ammonia as reactants are formed. In each case, the mixture settles into a composition in accord with the equilibrium constant of the reaction.

hydrogen, we were to add some ammonia, then the reaction would tend instead to form reactants at the expense of the added ammonia (Fig. 10.10).

Thinking point: Suppose one of the products of a reaction at equilibrium is a pure solid. How will the equilibrium be affected if some of the solid is removed? If all the solid is removed?

We can explain these responses thermodynamically by considering the relative sizes of Q and K (Fig. 10.11). When reactants are added, the reaction quotient Q falls below K, because the reactant concentrations in the denominator of Q increase. As we have seen, when $Q < K$, the reaction mixture responds by forming products until Q is restored to K. Likewise, when products are added, Q rises above K, because products appear in the numerator. Then, because $Q > K$, the reaction mixture responds by forming reactants at the expense of products until $Q = K$ again. It is important to understand that K is a constant that is not altered by changing concentrations. Only the value of Q changes, and always in a way that brings its value closer to that of K.

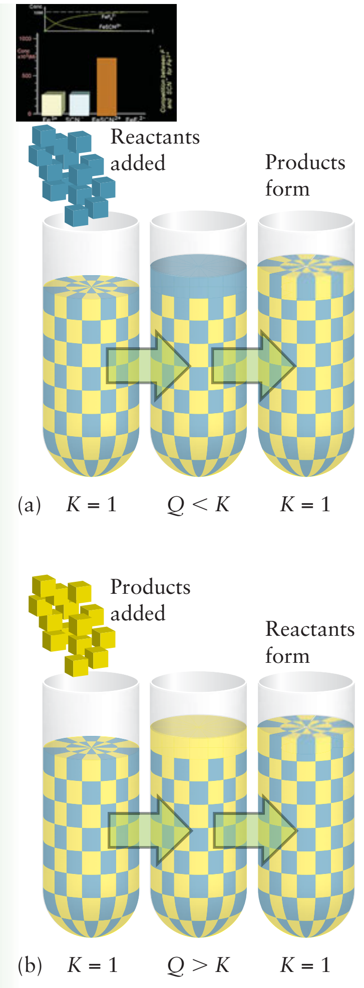

FIGURE 10.11 (a) When a reactant (blue) is added to a reaction mixture at equilibrium, $Q < K$ and products have a tendency to form. (b) When a product (yellow) is added instead, $Q > K$ and reactants tend to be formed. For this reaction, we have used $K = 1$ for the equilibrium blue $\rightleftharpoons$ yellow.

Animation 10.11

EXAMPLE 10.9 Predicting the effect of adding or removing reactants and products

Consider the equilibrium

$$4\,NH_3(g) + 3\,O_2(g) \rightleftharpoons 2\,N_2(g) + 6\,H_2O(g)$$

Predict the effect on each equilibrium concentration of (a) the addition of N_2; (b) the removal of NH_3; (c) the removal of H_2O.

Anticipate Because the addition of a reactant or the removal of a product cause a shift toward the formation of product, and vice versa, we should expect that (a) and (b) will shift the equilibrium toward reactants whereas (c) will shift the reaction toward products.

PLAN Consider how each change will affect the value of Q and what change is then needed to re-establish equilibrium.

SOLVE

For this reaction

$$Q = \frac{(P_{N_2})^2(P_{H_2O})^6}{(P_{NH_3})^4(P_{O_2})^3}$$

(a) The addition of N_2 (a product) to the equilibrium mixture increases Q above K, so the equilibrium adjusts as reactants are formed at the expense of products. (b) When NH_3 is removed from the system at equilibrium, Q rises above K so, once again, the equilibrium adjusts as reactants are formed at the expense of products. (c) The removal of H_2O reduces Q below K, so more products form at the expense of reactants.

Self-Test 10.12A Consider the equilibrium $SO_3(g) + NO(g) \rightleftharpoons SO_2(g) + NO_2(g)$. Predict the effect on the equilibrium of (a) the addition of NO; (b) the addition of NO_2; (c) the removal of SO_2.

Answer: The equilibrium tends to shift toward (a) products; (b) reactants; (c) products.]

Self-Test 10.12B Consider the equilibrium $CO(g) + 2\,H_2(g) \rightleftharpoons CH_3OH(g)$. Predict the effect on the equilibrium of (a) the addition of H_2; (b) the removal of CH_3OH; (c) the removal of CO.

Le Chatelier's principle suggests a good way of ensuring that a reaction goes on generating a substance: simply remove products as they are formed. In its continuing hunt for equilibrium, the reaction generates more product. Industrial processes rarely reach equilibrium, for just this reason. In the commercial synthesis of ammonia, for instance, ammonia can be continuously removed by circulating the equilibrium mixture through a refrigeration unit in which only the ammonia condenses. Therefore, the hydrogen and nitrogen continue to react to form more product.

EXAMPLE 10.10 Calculating the equilibrium composition after addition of a reagent

Suppose that the equilibrium mixture for the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$ considered in Example 10.8 is perturbed by adding 0.0100 mol $Cl_2(g)$ to the container (of volume 500. mL); then the system is once again allowed to reach equilibrium. Use this information and data from Example 10.8 to calculate the new composition of the equilibrium mixture.

Anticipate Because a product has been added, we expect the reaction to respond by producing more reactants.

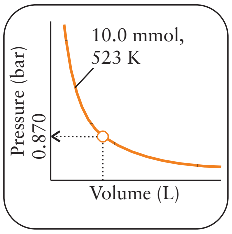
PLAN The general procedure is like that set out in Toolbox 10.1. Write the expression for the equilibrium constant, and then set up an equilibrium table. In this case, use as the initial partial pressures those found immediately after addition of the reagent, but before the reaction has responded. Obtain the initial equilibrium concentrations and the value of K from Example 10.8.

SOLVE From Example 10.8 the initial equilibrium partial pressures of the components are $P_{PCl_5} = 0.02$ bar, $P_{PCl_3} = 1.28$ bar, and $P_{Cl_2} = 1.28$ bar. The 0.0100 mol $Cl_2(g)$ added to the container corresponds to an additional partial pressure of chlorine of

From $P_J = n_J RT/V$,

$$P_{Cl_2} = \frac{(0.0100\ \text{mol}) \times (8.3145 \times 10^{-2}\ \text{L·bar·K}^{-1}\text{mol}^{-1}) \times (523\ \text{K})}{0.500\ \text{L}}$$

$$= 0.870\ \text{bar}$$



The total partial pressure of chlorine immediately after the addition of the chlorine gas is therefore 1.28 + 0.870 bar = 2.15 bar. We draw up the following table, with all partial pressures in bar, noting a decrease for partial pressures of the products and an increase for the partial pressure of the reactant.

	PCl_5	PCl_3	Cl_2
Step 1 Initial partial pressure	0.02	1.28	2.15
Step 2 Change in partial pressure	$+x$	$-x$	$-x$
Step 3 Equilibrium partial pressure	$0.02 + x$	$1.28 - x$	$2.15 - x$

Now we use the equilibrium constant to find x:

From $K = P_{PCl_3}P_{Cl_2}/P_{PCl_5}$,

$$K = \frac{(1.28 - x) \times (2.15 - x)}{0.02 + x} = \frac{2.75 - 3.43x + x^2}{0.02 + x}$$

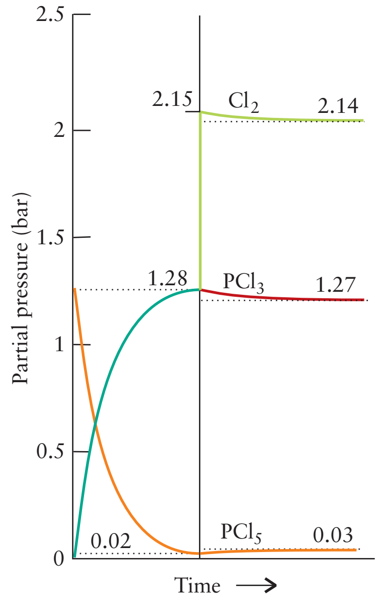


FIGURE 10.12 The response of the equilibrium mixture illustrated in Fig. 10.8 to the addition of chlorine. The curves for Cl_2 and PCl_3 are superimposed until the additional Cl_2 has been added.

Rearrange the equation with $K = 78.3$:

$$78.3 = \frac{2.75 - 3.43x + x^2}{0.02 + x}$$

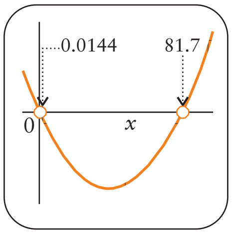
$$78.3(0.02 + x) = 2.75 - 3.43x + x^2$$

$$1.57 + 78.3x = 2.75 - 3.43x + x^2$$

Hence, $x^2 - 81.7x + 1.18 = 0$

Solve by using the quadratic formula.

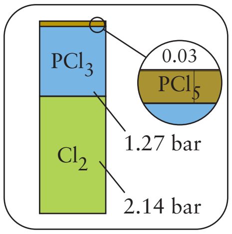
$x = 81.7$ and 0.0144



A note on good practice: Rounding to the correct number of significant figures should be carried out only at the end of a calculation to minimize rounding errors at intermediate stages of the calculation. Accordingly, although the product of 78.3×0.02, where 0.02 is a measured quantity with 1 sf, should be rounded to 2, we have retained it as 1.57.

We select $x = 0.0144$. It follows that, at equilibrium:

From $P_{PCl_5} = 0.02 + x$ bar, $P_{PCl_5} = 0.02 + 0.01$ bar $= 0.03$ bar
From $P_{PCl_3} = 1.28 - x$ bar, $P_{PCl_3} = 1.28 - 0.01$ bar $= 1.27$ bar
From $P_{Cl_2} = 2.15 - x$ bar, $P_{Cl_2} = 2.15 - 0.01$ bar $= 2.14$ bar



Evaluate As anticipated, the partial pressure of reactant has increased and the partial pressures of the products have decreased from their initial values (Fig. 10.12).

Self-Test 10.13A Suppose that the equilibrium mixture in Example 10.7 is perturbed by adding 3.00 mol N_2(g) and then the system is once again allowed to reach equilibrium. Use this information and data from Example 10.7 to calculate the new composition of the equilibrium mixture.

[***Answer:*** 23.2 bar N_2; 6.21 bar O_2; 1.0×10^{-12} bar N_2O]

Self-Test 10.13B Nitrogen, hydrogen, and ammonia gases have reached equilibrium in a container of volume 1.00 L at 298 K. Equilibrium partial pressures are 0.080 atm N_2, 0.050 atm H_2, and 2.60 atm NH_3. For $N_2(g) + 3\,H_2(g) \rightleftharpoons 2\,NH_3(g)$, $K = 6.8 \times 10^5$. Calculate the new equilibrium partial pressures if half the NH_3 is removed from the container and equilibrium is reestablished.

When the equilibrium composition is perturbed by adding or removing a reactant or product, reaction tends to occur in the direction that restores the value of Q to that of K.

10.10 Compressing a Reaction Mixture

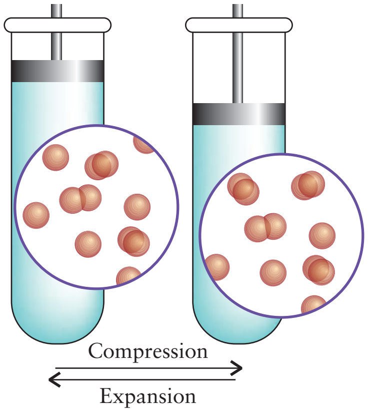


FIGURE 10.13 Le Chatelier's principle predicts that, when a reaction at equilibrium is compressed, the number of molecules in the gas phase will tend to decrease. This diagram illustrates the effect of compression and expansion on the dissociation equilibrium of a diatomic molecule. Note the increase in the relative concentration of diatomic molecules as the system is compressed and the decrease when the system expands.

A gas-phase equilibrium may respond to compression—a reduction in volume—of the reaction vessel. According to Le Chatelier's principle, the composition will tend to change in a way that minimizes the resulting increase in pressure. For instance, in the dissociation of gaseous I_2 to form I atoms, $I_2(g) \rightleftharpoons 2\,I(g)$, 1 mol of gaseous reactant molecules produces 2 mol of gaseous product molecules. The forward reaction increases the number of particles in the container and hence the total pressure of the system and the reverse reaction decreases it. It follows that, when the mixture is compressed, the equilibrium composition will tend to shift in favor of the reactant, I_2, because that response minimizes the increase in pressure (Fig. 10.13). Expansion of the system

would result in the opposite response, a tendency for I_2 to dissociate to free atoms. In the formation of ammonia, 2 mol of gas molecules are produced from 4 mol of gas molecules. Therefore, Haber realized that, to increase the yield of ammonia, he needed to carry out the synthesis with highly compressed gases. The actual industrial process uses pressures of 250 atm and more (Fig. 10.14).

FIGURE 10.14 One of the high-pressure vessels used for the catalytic synthesis of ammonia. The vessel must be able to withstand internal pressures of greater than 250 atm.

EXAMPLE 10.11 Predicting the effect of compression on an equilibrium

Predict the effect of compression on the equilibrium composition of the reaction mixtures in which the equilibria (a) $2\ NO_2(g) \rightleftharpoons N_2O_4(g)$ and (b) $H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$ have been established.

PLAN Reaction will take place in the direction that reduces the increase in pressure and fewer gas molecules generate a lower pressure. Therefore, compare the number of reactant gas molecules with the number of product gas molecules.

SOLVE (a) In the forward reaction, two NO_2 molecules combine to form one N_2O_4 molecule. Hence, compression favors the formation of N_2O_4. (b) Because neither direction corresponds to a reduction of gas-phase molecules, compressing the mixture should have no effect on the composition of the equilibrium mixture. (In practice, there will be a small effect due to the nonideality of the gases.)

Self-Test 10.14A Predict the effect of compression on the equilibrium composition of the reaction $CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3\ H_2(g)$.

[***Answer:*** Reactants favored]

Self-Test 10.14B Predict the effect of compression on the equilibrium composition of the reaction $CO_2(g) + H_2O(l) \rightleftharpoons H_2CO_3(aq)$.

We can justify the effect of compression on an equilibrium mixture mathematically by showing that compressing a system will change Q, and the reaction tends to adjust in the direction that restores the value of Q to that of K.

HOW DO WE DO THAT?

Suppose we want to discover the effect of compression on the equilibrium in Example 10.11a. We write the equilibrium constant in its complete form (to be careful with units) as

$$2\ NO_2(g) \rightleftharpoons N_2O_4(g) \qquad K = \frac{P_{N_2O_4}/P^\circ}{(P_{NO_2}/P^\circ)^2}$$

Next, we express K in terms of the volume of the system:

From $P_J = n_J RT/V$,

$$K = \frac{n_{N_2O_4}RT/VP^\circ}{(n_{NO_2}RT/VP^\circ)^2} = \frac{n_{N_2O_4}P^\circ V}{(n_{NO_2})^2 RT}$$

As it should be, this K remains unitless. Now, because P°/RT is a constant at constant temperature, for K to remain constant when the volume (V) of the system is reduced, the ratio $n_{N_2O_4}/(n_{NO_2})^2$ must increase. That is, the amount of NO_2 must decrease and the amount of N_2O_4 must increase. Therefore, as we have seen before, as the volume of the system is decreased, the equilibrium shifts to a smaller total number of gas molecules. Conversely, if the system were expanded, the equilibrium would shift in the direction of a larger total number of gas molecules.

Suppose that we were to increase the total pressure inside a reaction vessel by pumping in argon or some other inert gas at constant volume. The reacting gases continue to occupy the same volume, and so their individual molar concentrations and partial pressures remain unchanged despite the presence of an inert gas. In this case, therefore, provided that the gases can be regarded as ideal, the equilibrium composition is unaffected despite the fact that the total pressure has increased.

Compression of a reaction mixture at equilibrium tends to drive the reaction in the direction that reduces the number of gas-phase molecules; increasing the pressure by introducing an inert gas has no effect on the equilibrium composition.

10.11 Temperature and Equilibrium

The equilibrium constant is unchanged when concentrations or pressures change. However, we can see from Table 10.2 that the equilibrium constant does change with temperature. For an exothermic reaction, the formation of products is found experimentally to be favored by lowering the temperature. Conversely, for an endothermic reaction, the products are favored by an *increase* in temperature.

Le Chatelier's principle is consistent with these observations. We can imagine the heat generated in an exothermic reaction as helping to offset lowering the temperature. Similarly, we can imagine the heat absorbed in an endothermic reaction as helping to offset an increase in temperature. In other words, *raising the temperature of a reaction mixture at equilibrium will shift the reaction in the endothermic direction*. An example is the decomposition of carbonates. A reaction such as

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

is strongly endothermic in the forward direction, and an appreciable partial pressure of carbon dioxide is present at equilibrium only if the temperature is high. For instance, at 800°C, the partial pressure is 0.22 atm at equilibrium. If the heating takes place in an open container, this partial pressure is never reached, because equilibrium is never reached. The gas drifts away, and the calcium carbonate decomposes completely, leaving a solid residue of CaO. However, if the surroundings are already so rich in carbon dioxide that its partial pressure exceeds 0.22 atm, then virtually no decomposition occurs: for every CO_2 molecule that is formed, one is converted back into carbonate. This dynamic process is probably what happens on the hot surface of Venus (Fig. 10.15), where the partial pressure of carbon dioxide is about 87 atm. This high pressure has led to speculation that the planet's surface is rich in carbonates, despite its high temperature (about 500°C).

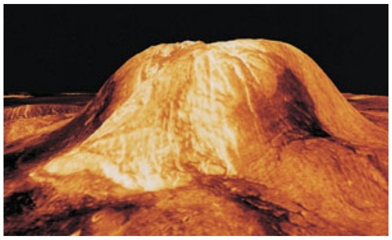

FIGURE 10.15 A radar image of the surface of Venus. Although the rocks are very hot, the partial pressure of carbon dioxide in the atmosphere is so great that carbonates may be abundant.

EXAMPLE 10.12 Predicting the effect of temperature on an equilibrium

One stage in the manufacture of sulfuric acid is the formation of sulfur trioxide by the reaction of SO_2 with O_2 in the presence of a vanadium(V) oxide catalyst. Predict how the equilibrium composition for the sulfur trioxide synthesis will tend to change when the temperature is raised.

Anticipate Raising the temperature of an equilibrium mixture will tend to shift its composition in the endothermic direction of the reaction. Combustion reactions are all exothermic, so we should expect the equilibrium of this reaction (which can be viewed as the combustion of sulfur dioxide) to shift in favor of reactants.

PLAN We need to verify that the reaction is exothermic. To find the standard reaction enthalpy, use the standard enthalpies of formation given in Appendix 2A.

SOLVE The chemical equation is

$$2\,SO_2(g) + O_2(g) \xrightleftharpoons{V_2O_5} 2\,SO_3(g)$$

The standard reaction enthalpy of the forward reaction is

$$\begin{aligned}\Delta H° &= (2\text{ mol}) \times \Delta H_f°(SO_3, g) - (2\text{ mol}) \times \Delta H_f°(SO_2, g)\\ &= 2(-395.72\text{ kJ}) - 2(-296.83\text{ kJ}) = -197.78\text{ kJ}\end{aligned}$$

Evaluate Because the formation of SO_3 is exothermic, the reverse reaction is endothermic. Hence, raising the temperature of the equilibrium mixture favors the decomposition of SO_3 to SO_2 and O_2; as a consequence, the pressures of SO_2 and O_2 will increase and that of SO_3 will decrease, as we anticipated.

Self-Test 10.15A Predict the effect of raising the temperature on the equilibrium composition of the reaction $N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$. See Appendix 2A for data.

[***Answer:*** The pressure of NO_2 will increase.]

Self-Test 10.15B Predict the effect of lowering the temperature on the equilibrium composition of the $2\ CO(g) + O_2(g) \rightleftharpoons 2\ CO_2(g)$. See Appendix 2A for data.

The effect of temperature on the equilibrium composition arises from the dependence of the equilibrium constant on the temperature. The relation between the equilibrium constant and the standard Gibbs free energy of reaction in Eq. 8 applies to any temperature. Therefore, we should be able to use it to relate the equilibrium constant at one temperature to its value at another temperature.

HOW DO WE DO THAT?

To find the quantitative relation between the equilibrium constants for the same reaction at two temperatures T_1 and T_2, we note that Eq. 8 allows us to write the relation between standard Gibbs free energies of reaction and the equilibrium constants K_1 and K_2 at the two temperatures:

$$\Delta G_{r,1}° = -RT_1 \ln K_1 \qquad \Delta G_{r,2}° = -RT_2 \ln K_2$$

These two expressions rearrange to

$$\ln K_1 = -\frac{\Delta G_{r,1}°}{RT_1} \qquad \ln K_2 = -\frac{\Delta G_{r,2}°}{RT_2}$$

Subtraction of the second from the first gives

$$\ln K_1 - \ln K_2 = -\frac{1}{R}\left\{\frac{\Delta G_{r,1}°}{T_1} - \frac{\Delta G_{r,2}°}{T_2}\right\}$$

At this point, we introduce the definition of $\Delta G_r°$ in terms of $\Delta H_r°$ and $\Delta S_r°$:

$$\Delta G_{r,1}° = \Delta H_{r,1}° - T_1\Delta S_{r,1}° \qquad \Delta G_{r,2}° = \Delta H_{r,2}° - T_2\Delta S_{r,2}°$$

which gives

$$\ln K_1 - \ln K_2 = -\frac{1}{R}\left\{\frac{\Delta H_{r,1}° - T_1\Delta S_{r,1}°}{T_1} - \frac{\Delta H_{r,2}° - T_2\Delta S_{r,2}°}{T_2}\right\}$$
$$= -\frac{1}{R}\left\{\frac{\Delta H_{r,1}°}{T_1} - \frac{\Delta H_{r,2}°}{T_2} - \Delta S_{r,1}° + \Delta S_{r,2}°\right\}$$

It is usually reasonable to assume that $\Delta H_r°$ and $\Delta S_r°$ are both approximately independent of temperature over the range of temperatures of interest. When we make that approximation, the reaction entropies cancel, and we are left with

$$\ln K_1 - \ln K_2 = -\frac{\Delta H_r°}{R}\left\{\frac{1}{T_1} - \frac{1}{T_2}\right\}$$

A note on good practice: Notice that we have used the "molar" convention for the thermodynamic functions, as this convention is required by Eq. 8.

The expression that we have just derived is a quantitative version of Le Chatelier's principle for the effect of temperature. It is normally rearranged (by multiplying through by -1 and then using $\ln a - \ln b = \ln(a/b)$) into the **van 't Hoff equation:**

$$\ln\frac{K_2}{K_1} = \frac{\Delta H_r°}{R}\left\{\frac{1}{T_1} - \frac{1}{T_2}\right\} \qquad (13)^*$$

This equation is sometimes called the van 't Hoff isochore, to distinguish it from van 't Hoff's osmotic pressure equation (Section 9.17). An isochore is the plot of an equation for a constant-volume process.

In this expression, K_1 is the equilibrium constant when the temperature is T_1 and K_2 is the equilibrium constant when the temperature is T_2.

What does this equation tell us? If the reaction is endothermic, then $\Delta H_r°$ is positive. If $T_2 > T_1$, then $1/T_2 < 1/T_1$ and the term in braces is also positive. Therefore, $\ln(K_2/K_1)$ is positive, which implies that $K_2/K_1 > 1$ and therefore that $K_2 > K_1$. In other words, an increase in temperature favors the formation of product if the reaction is endothermic. We predict the opposite effect for an exothermic reaction because $\Delta H_r°$ is then negative. Therefore, the van 't Hoff equation accounts for Le Chatelier's principle for the effect of temperature on an equilibrium.

One word of warning: when using the van 't Hoff equation for reactions involving gases, the equilibrium constants must be K, not K_c. If we want a new value for K_c for a gas-phase reaction, we convert from K_c into K at the initial temperature (by using Eq. 12), use the van 't Hoff equation to calculate the value of K at the new temperature, and then convert that K into the new K_c by using Eq. 12 at the new temperature.

EXAMPLE 10.13 Predicting the value of an equilibrium constant at a different temperature

The equilibrium constant K for the synthesis of ammonia (reaction C) is 6.8×10^5 at 298 K. Predict its value at 400. K.

Anticipate The synthesis of ammonia is exothermic, and so we expect the equilibrium constant to be smaller at the higher temperature.

PLAN To use the van 't Hoff equation, we need the standard reaction enthalpy, which can be calculated from the standard enthalpies of formation in Appendix 2A. Equation 13 requires us to use the "molar" convention.

What should we assume? That the gases are ideal and that the reaction enthalpy is constant over the temperature range of interest.

SOLVE The standard reaction enthalpy for the forward reaction in C is

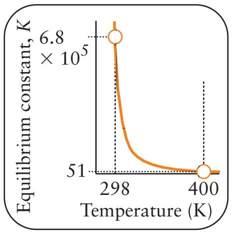
$$\begin{aligned}\Delta H_r° &= 2\Delta H_f°(NH_3, g) = 2(-46.11\ kJ\cdot mol^{-1})\\ &= -92.22\ kJ\cdot mol^{-1} \text{ or } -92.22 \times 10^3\ J\cdot mol^{-1}\end{aligned}$$

From $\ln(K_2/K_1) = (\Delta H_r°/R)\{(1/T_1) - (1/T_2)\}$,

$$\ln\frac{K_2}{K_1} = \frac{\overbrace{-9.222 \times 10^4\ J\cdot mol^{-1}}^{-92.22\ kJ\cdot mol^{-1}}}{8.3145\ J\cdot K^{-1}\cdot mol^{-1}} \times \left(\frac{1}{298\ K} - \frac{1}{400.\ K}\right) = -9.49$$

Take antilogarithms (e^x).

$$\begin{aligned}K_2 &= K_1 e^{-9.49}\\ &= (6.8 \times 10^5) \times e^{-9.49}\\ &= 51\end{aligned}$$



Evaluate The equilibrium constant at 400. K is smaller, as expected, and is close to the experimental value of 41 in Table 10.2. It is not exactly the same because $\Delta H_r°$ may change slightly over the temperature range in question.

Self-Test 10.16A The equilibrium constant K for $2\ SO_3(g) \rightleftharpoons 2\ SO_2(g) + O_2(g)$ is 2.5×10^{-25} at 298 K. Predict its value at 500. K.

[***Answer:*** 2.5×10^{-11}]

Self-Test 10.16B The equilibrium constant K for $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$ is 78.3 at 523 K. Predict its value at 800. K.

Raising the temperature of an exothermic reaction favors the formation of reactants; raising the temperature of an endothermic reaction favors the formation of products. The van 't Hoff equation expresses the effect quantitatively.

10.12 Catalysts and Haber's Achievement

A **catalyst** is a substance that increases the rate of a chemical reaction without being consumed itself. We shall see a lot more of catalysts later, when we consider reaction rates in Chapter 14. However, it is important to be aware at this stage that a catalyst has no effect on the equilibrium composition of a reaction mixture. A catalyst can speed up the rate at which a reaction reaches equilibrium, but it does not affect the composition at equilibrium. It acts by providing a faster route to the same destination.

A catalyst speeds up both the forward and the reverse reactions to the same extent. Therefore, the dynamic equilibrium is unaffected. The thermodynamic justification of this observation is based on the fact that the equilibrium constant depends only on the temperature and the value of $\Delta G_r°$. A standard Gibbs free energy of reaction depends only on the identities of the reactants and products and is independent of the rate of the reaction or the presence of any substances that do not appear in the overall chemical equation for the reaction. The fact that a catalyst is present to provide a different route between reactants and products has no effect on the value of $\Delta G_r°$ and therefore no effect on the value of K.

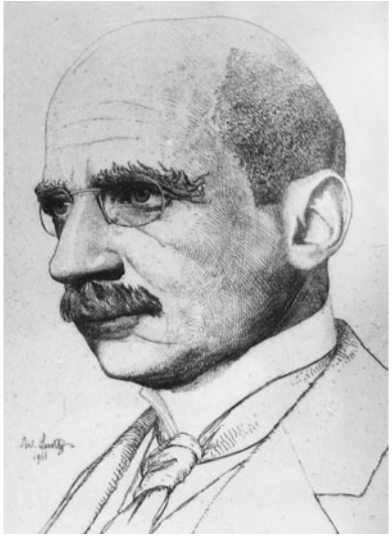


FIGURE 10.16 Fritz Haber (1868–1934).

We have seen how Haber's understanding of chemical equilibrium enabled him to increase the yield of ammonia (Fig. 10.16). He realized that he had to compress the gases and remove the ammonia as it was formed. As we have seen, compression shifts the equilibrium composition in favor of ammonia, which increases the yield of product. Removing the ammonia also encourages more to be formed. In addition, Haber realized that he should run the reaction at as low a temperature as possible: low temperature favors the formation of product because the reaction is exothermic. However, nitrogen and hydrogen combine too slowly at low temperatures, and so Haber solved this problem by developing an appropriate catalyst (he used osmium and later uranium). The process was brought to an industrial scale by the chemical engineer Carl Bosch, who identified a cheaper catalyst (iron) and overcame the enormous problems of working at high pressure, which makes even hydrogen corrosive. Their process is still in use throughout the world. In the United States alone, it accounts for almost the entire annual production of about 1.6×10^{10} kg of ammonia (Fig. 10.17).

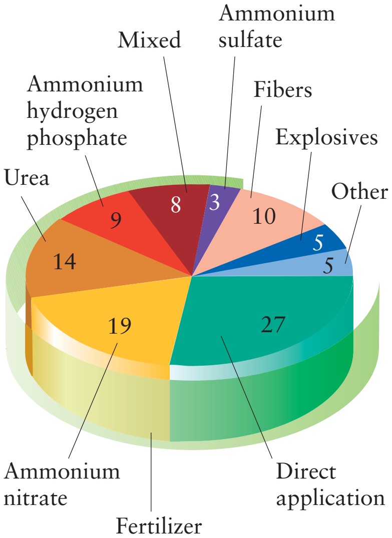

FIGURE 10.17 The Haber process is still used to produce almost all the ammonia manufactured in the world. This pie chart shows how the ammonia is used. The figures are percentages. Note that 80%—as shown by the green band—is used as fertilizer, either directly or after conversion into another compound.

A catalyst does not affect the equilibrium composition of a reaction mixture.

10.13 The Impact on Biology: Homeostasis

Because a living being is not a closed system, true equilibrium in living systems can be reached only for very fast reactions such as those between acids and bases. In general, however, our bodies maintain certain relatively constant characteristics such as temperature and levels of certain chemicals in the blood. A beneficial environment in the body is maintained through the process of **homeostasis,** the maintenance of constant internal conditions. Homeostasis is not a true equilibrium, because there are usually slight variations above and below the desired point. However, it responds to changes in conditions in the same way as a system in chemical equilibrium and so is governed by Le Chatelier's principle.

An important homeostatic biological process that involves chemical equilibria is the transport of oxygen. Most of the oxygen in the blood is carried by hemoglobin (Hb).

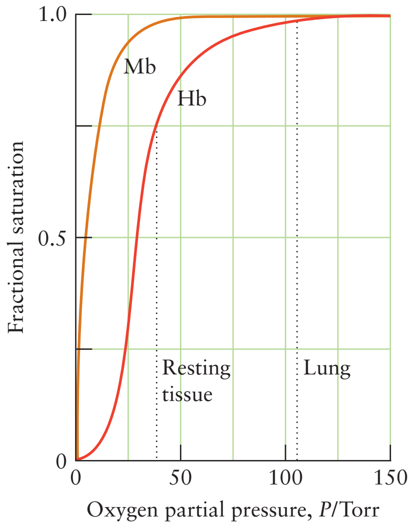

FIGURE 10.18 The variation of the extent of saturation of myoglobin (Mb) and hemoglobin (Hb) with the partial pressure of oxygen. The different shapes of the curves account for the different biological functions of the two proteins.

When blood flows through lung tissues, about 98% of the hemoglobin molecules pick up oxygen molecules and a small amount of additional oxygen simply dissolves in the blood plasma (the solution in which blood cells are suspended). However, when blood enters the small blood vessels called capillaries in muscle tissue far from the lungs, the hemoglobin molecules are surrounded by tissues that are depleted in oxygen. The equilibrium

$$\mathrm{Hb(aq)} + \mathrm{O_2(aq)} \rightleftharpoons \mathrm{HbO_2(aq)}$$

is shifted toward reactants as some of the hemoglobin molecules release their oxygen molecules to re-establish the equilibrium compositions. When a person is exercising heavily, muscles use an additional mechanism to encourage the hemoglobin molecules to release oxygen in the muscle tissue. Hydrogen ions from acids can cause the oxygen molecules in hemoglobin to be released; so, when lactic acid is produced by working muscle tissue, additional oxygen molecules are released from the hemoglobin.

Figure 10.18 shows how the O_2 uptake by hemoglobin and myoglobin (Mb), the oxygen storage protein, varies with partial pressure of oxygen. The shape of the Hb saturation curve means that Hb can load O_2 almost as fully in the lungs as Mb and unload it more completely than Mb in different regions of the organism. In the lungs, where $P_{O_2} \approx 105$ Torr, 98% of the molecules have taken up O_2, resulting in almost complete saturation. In resting muscular tissue, the concentration of O_2 corresponds to a partial pressure of about 40 Torr, at which value 75% of the Hb molecules are saturated with oxygen. This figure implies that sufficient oxygen is still available should a sudden surge of activity take place. If the local partial pressure falls to 20 Torr, the fraction of Hb molecules saturated falls to about 10%. Note that the steepest part of the curve falls in the range of typical tissue oxygen partial pressure. Myoglobin, on the other hand, begins to release O_2 only when P_{O_2} has fallen below about 20 Torr, and so it acts as a reserve to be drawn on only when the Hb oxygen has been used up.

Overloading the body's coping mechanisms can lead to failure to maintain homeostasis. The result can be sudden and even fatal illness. Mountain climbers encounter low oxygen conditions at high altitudes and, if they climb vigorously, their lungs may not be able to provide sufficient oxygen to maintain homeostasis. For this reason, mountain climbers spend some time in high-altitude base camps before climbing, so that their bodies can adjust by producing more hemoglobin molecules.

Homeostasis, a mechanism similar to chemical equilibrium, allows living organisms to control biological processes at a constant level.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Distinguish homogeneous and heterogeneous equilibria and write equilibrium constants for both types of reaction from a balanced equation (Example 10.1 and Self-Tests 10.2 and 10.5).

❑ 2 Relate the Gibbs free energy of reaction to the composition of the reaction mixture (Example 10.2).

❑ 3 Calculate an equilibrium constant from a standard Gibbs free energy (Example 10.3).

❑ 4 Calculate an equilibrium concentration (Example 10.4).

❑ 5 Predict the direction of a reaction, given K and the concentrations of reactants and products (Example 10.5).

❑ 6 Convert between K and K_c (Example 10.6).

❑ 7 Calculate the effect on K of reversing a reaction or multiplying the chemical equation by a factor (Section 10.7).

❑ 8 Use an equilibrium table to carry out equilibrium calculations (Toolbox 10.1 and Examples 10.7, 10.8, and 10.10).

❑ 9 Use Le Chatelier's principle to predict how the equilibrium composition of a reaction mixture is affected by adding or removing reagents, compressing or expanding the mixture, or changing the temperature (Examples 10.9, 10.11, and 10.12).

❑ 10 Predict the value of K at a different temperature (Example 10.13).

EXERCISES

The Equilibrium Constant

10.1 State whether the following statements are true or false. If false, explain why.
(a) A reaction stops when equilibrium is reached.
(b) An equilibrium reaction is not affected by increasing the concentrations of products.
(c) If one starts with a higher pressure of reactant, the equilibrium constant will be larger.
(d) If one starts with higher concentrations of reactants, the equilibrium concentrations of the products will be larger.

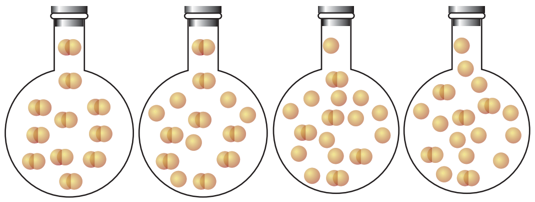
10.2 Determine whether the following statements are true or false. If false, explain why.

(a) In an equilibrium reaction, the reverse reaction begins only when all reactants have been converted to products.
(b) The equilibrium concentrations will be the same whether one starts with pure reactants or pure products.
(c) The rates of the forward and reverse reactions are the same at equilibrium.
(d) If the Gibbs free energy is greater than the standard Gibbs free energy of reaction, the reaction proceeds forward to equilibrium.

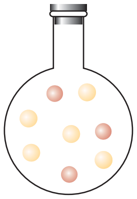
10.3 Depict the progress of the reaction graphically (as in Fig. 10.1) for the decomposition of PCl_5 to give PCl_3 and Cl_2, using the values given in Example 10.8.

10.4 Depict the progress of the reaction graphically (as in Fig. 10.1) for the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$, using the conditions described in Example 10.10, starting from the point where additional Cl_2 is added and continuing until equilibrium is restored.

10.5 The following flasks show the dissociation of a diatomic molecule, X_2, over time. (a) Which flask represents the point in time at which the reaction has reached equilibrium? (b) What percentage of the X_2 molecules have decomposed at equilibrium? (c) Assuming that the initial pressure of X_2 was 0.10 bar, calculate the value of K for the decomposition.



10.6 The flask below contains atoms of A (red) and B (yellow). They react as follows: $2\ A(g) + B(g) \rightleftharpoons A_2B(g)$, $K = 0.25$. Draw a picture of the flask after it has reached equilibrium.



10.7 Balance the following equations using the smallest whole-number coefficients, then write the equilibrium expression K_c for each reaction:
(a) $CH_4(g) + O_2(g) \rightleftharpoons CO_2(g) + H_2O(g)$
(b) $I_2(g) + F_2(g) \rightleftharpoons IF_5(g)$
(c) $NO_2(g) + F_2(g) \rightleftharpoons FNO_2(g)$

10.8 Balance the following equations using the smallest whole-number coefficients, then write the equilibrium expression K_c for each reaction:
(a) $CH_4(g) + Cl_2(g) \rightleftharpoons CHCl_3(g) + HCl(g)$
(b) $NH_3(g) + ClF_3(g) \rightleftharpoons HF(g) + N_2(g) + Cl_2(g)$
(c) $N_2(g) + O_2(g) \rightleftharpoons N_2O_3(g)$

10.9 A 0.10-mol sample of pure ozone, O_3, is placed in a sealed 1.0-L container and the reaction $2\ O_3(g) \rightleftharpoons 3\ O_2(g)$ is allowed to reach equilibrium. A 0.50-mol sample of pure ozone is placed in a second 1.0-L container at the same temperature and allowed to reach equilibrium. Without doing any calculations, predict which of the following will be different in the two containers at equilibrium. Which will be the same? (a) Amount of O_2; (b) concentration of O_2; (c) the ratio $[O_2]/[O_3]$; (d) the ratio $[O_2]^3/[O_3]^2$; (e) the ratio $[O_3]^2/[O_2]^3$. Explain each of your answers.

10.10 A 0.10-mol sample of $H_2(g)$ and a 0.10-mol sample of $Br_2(g)$ are placed into a 2.0-L container. The reaction $H_2(g) + Br_2(g) \rightleftharpoons 2\ HBr(g)$ is then allowed to come to equilibrium. A 0.20-mol sample of HBr is placed into a second 2.0-L sealed container at the same temperature and allowed to reach equilibrium with H_2 and Br_2. Which of the following will be different in the two containers at equilibrium? Which will be the same? (a) Amount of Br_2; (b) concentration of H_2; (c) the ratio $[HBr]/[H_2][Br_2]$; (d) the ratio $[HBr]/[Br_2]$; (e) the ratio $[HBr]^2/[H_2][Br_2]$; (f) the total pressure in the container. Explain each of your answers.

10.11 Use the following data, which were collected at 460.°C and are equilibrium partial pressures, to determine K for the reaction $H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$:

P_{H_2} (bar)	P_{I_2} (bar)	P_{HI} (bar)
6.47×10^{-3}	0.594×10^{-3}	0.0137
3.84×10^{-3}	1.52×10^{-3}	0.0169
1.43×10^{-3}	1.43×10^{-3}	0.0100

10.12 Determine K from the following equilibrium data collected at 24°C for the reaction $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$:

P_{NH_3} (bar)	P_{H_2S} (bar)
0.307	0.307
0.364	0.258
0.539	0.17

10.13 Write the reaction quotient Q for
(a) $2\ BCl_3(g) + 2\ Hg(l) \longrightarrow B_2Cl_4(s) + Hg_2Cl_2(s)$
(b) $P_4S_{10}(s) + 16\ H_2O(l) \longrightarrow 4\ H_3PO_4(aq) + 10\ H_2S(aq)$
(c) $Br_2(g) + 3\ F_2(g) \longrightarrow 2\ BrF_3(g)$

10.14 Write the reaction quotient Q_c for
(a) $NCl_3(g) + 3\ H_2O(l) \longrightarrow NH_3(g) + 3\ HOCl(aq)$
(b) $P_4(s) + 3\ KOH(aq) + 3\ H_2O(l) \longrightarrow PH_3(aq) + 3\ KH_2PO_2(aq)$
(c) $CO_3^{2-}(aq) + 2\ H_3O^+(aq) \longrightarrow CO_2(g) + 3\ H_2O(l)$

10.15 (a) Calculate the reaction Gibbs free energy of $I_2(g) \longrightarrow 2\ I(g)$ at 1200. K ($K = 6.8$) when the partial pressures of I_2 and I are 0.13 bar and 0.98 bar, respectively. (b) What is the spontaneous direction of the reaction? Explain briefly.

10.16 Calculate the reaction Gibbs free energy of $PCl_3(g) + Cl_2(g) \longrightarrow PCl_5(g)$ at 230.°C when the partial pressures of PCl_3, Cl_2, and PCl_5 are 0.13 bar, 0.51 bar, and 1.42 bar, respectively. What is the spontaneous direction of change, given that $K = 49$ at 230.°C?

10.17 (a) Calculate the reaction Gibbs free energy of $N_2(g) + 3\ H_2(g) \longrightarrow 2\ NH_3(g)$ when the partial pressures of N_2, H_2, and NH_3 are 4.2 bar, 1.8 bar, and 21 bar, respectively, and the temperature is 400. K. For this reaction, $K = 41$ at 400. K.
(b) Indicate whether this reaction mixture is likely to form reactants, is likely to form products, or is at equilibrium.

10.18 (a) Calculate the reaction Gibbs free energy of $H_2(g) + I_2(g) \longrightarrow 2\ HI(g)$ at 700. K when the partial pressures of H_2, I_2, and HI are 0.35 bar, 0.18 bar, and 2.85 bar, respectively. For this reaction, $K = 54$ at 700. K. (b) Indicate whether this reaction mixture is likely to form reactants, is likely to form products, or is at equilibrium.

10.19 Calculate the equilibrium constant at 25°C for each of the following reactions, using data in Appendix 2A:
(a) the combustion of hydrogen: $2\ H_2(g) + O_2(g) \rightleftharpoons 2\ H_2O(g)$
(b) the oxidation of carbon monoxide: $2\ CO(g) + O_2(g) \rightleftharpoons 2\ CO_2(g)$
(c) the decomposition of limestone: $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$

10.20 Calculate the equilibrium constant at 25°C for each of the following reactions, by using data in Appendix 2A:
(a) the synthesis of trichloromethane (chloroform) from natural gas (methane). $\Delta G_r°(CH_3Cl, g) = 48.5\ kJ \cdot mol^{-1}$
$CH_4(g) + Cl_2(g) \rightleftharpoons CH_3Cl(g) + HCl(g)$
(b) the hydrogenation of acetylene to ethane:
$C_2H_2(g) + 2\ H_2(g) \rightleftharpoons C_2H_6(g)$
(c) the final step in the industrial production of nitric acid:
$3\ NO_2(g) + H_2O(l) \rightleftharpoons 2\ HNO_3(aq) + NO(g)$
(d) the reaction of hydrazine and oxygen in a rocket:
$N_2H_4(l) + O_2(g) \rightleftharpoons N_2(g) + 2\ H_2O(l)$

10.21 Calculate the standard Gibbs free energy of each of the following reactions:
(a) $I_2(g) \rightleftharpoons 2\ I(g)$, $K = 6.8$ at 1200. K
(b) $Ag_2CrO_4(s) \rightleftharpoons 2\ Ag^+(aq) + CrO_4^{2-}(aq)$, $K = 1.1 \times 10^{-12}$ at 298 K

10.22 Calculate the standard Gibbs free energy for each of the following reactions:
(a) $H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$, $K = 54$ at 700. K
(b) $CCl_3COOH(aq) + H_2O(l) \rightleftharpoons CCl_3CO_2^-(aq) + H_3O^+(aq)$, $K = 0.30$ at 298 K

10.23 If $Q = 1.0$ for the reaction $N_2(g) + O_2(g) \longrightarrow 2\ NO(g)$ at 25°C, will the reaction have a tendency to form products or reactants or will it be at equilibrium?

10.24 If $Q = 1.0 \times 10^{40}$ for the reaction $C(s) + O(g) \longrightarrow CO(g)$ at 25°C, will the reaction have a tendency to form products or reactants or will it be at equilibrium?

10.25 Use the information in Table 10.2 to determine the value of K at 300 K for the reaction $2\ BrCl(g) + H_2(g) \rightleftharpoons Br_2(g) + 2\ HCl(g)$.

10.26 Use the information in Table 10.2 to determine the value of K at 500 K for the reaction $2\ NH_3(g) + 3\ Br_2(g) \rightleftharpoons N_2(g) + 6\ HBr(g)$.

10.27 In a gas-phase equilibrium mixture of H_2, I_2, and HI at 500. K, $[HI] = 2.21 \times 10^{-3}\ mol \cdot L^{-1}$ and $[I_2] = 1.46 \times 10^{-3}\ mol \cdot L^{-1}$. Given the value of the equilibrium constant in Table 10.2, calculate the concentration of H_2.

10.28 In a gas-phase equilibrium mixture of H_2, Cl_2, and HCl at 1000. K, $[HCl] = 1.45\ mmol \cdot L^{-1}$ and $[Cl_2] = 2.45\ mmol \cdot L^{-1}$. Use the information in Table 10.2 to calculate the concentration of H_2.

10.29 In a gas-phase equilibrium mixture of PCl_5, PCl_3, and Cl_2 at 500. K, $P_{PCl_5} = 1.18$ bar, $P_{Cl_2} = 5.43$ bar. What is the partial pressure of PCl_3, given that $K = 25$ for the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$?

10.30 In a gas-phase equilibrium mixture of $SbCl_5$, $SbCl_3$, and Cl_2 at 500. K, $P_{SbCl_5} = 0.072$ bar and $P_{SbCl_3} = 5.02$ mbar. Calculate the equilibrium partial pressure of Cl_2, given that $K = 3.5 \times 10^{-4}$ for the reaction $SbCl_5(g) \rightleftharpoons SbCl_3(g) + Cl_2(g)$.

10.31 For the reaction $H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$, $K = 160.$ at 500. K. An analysis of a reaction mixture at 500. K showed that it had the composition $P_{H_2} = 0.20$ bar, $P_{I_2} = 0.10$ bar, and $P_{HI} = 0.10$ bar. (a) Calculate the reaction quotient. (b) Is the reaction mixture at equilibrium? (c) If not, is there a tendency to form more reactants or more products?

10.32 Analysis of a reaction mixture showed that it had the composition $0.624\ mol \cdot L^{-1}\ N_2$, $0.315\ mol \cdot L^{-1}\ H_2$, and $0.222\ mol \cdot L^{-1}\ NH_3$ at 800. K, at which temperature $K_c = 0.278$ for $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$. (a) Calculate the reaction quotient Q_c. (b) Is the reaction mixture at equilibrium? (c) If not, is there a tendency to form more reactants or more products?

10.33 A 0.500-L reaction vessel at 700. K contains 1.20 mmol $SO_2(g)$, 0.50 mmol $O_2(g)$, and 0.10 mmol $SO_3(g)$. At 700. K, $K_c = 1.7 \times 10^6$ for the equilibrium $2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$. (a) Calculate the reaction quotient Q_c. (b) Will more $SO_3(g)$ tend to form?

10.34 Given that $K_c = 62$ for the reaction $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$ at 500. K, calculate whether more ammonia will tend to form when a mixture of composition $2.23\ mmol \cdot L^{-1}\ N_2$, $1.24\ mmol \cdot L^{-1}\ H_2$, and $0.112\ mmol \cdot L^{-1}\ NH_3$ is present in a container at 500. K.

10.35 Determine K_c for each of the following equilibria from the value of K:
(a) $2\ NOCl(g) \rightleftharpoons 2\ NO(g) + Cl_2(g)$, $K = 1.8 \times 10^{-2}$ at 500. K
(b) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$, $K = 167$ at 1073 K

10.36 Determine K_c for each of the following equilibria from the value of K:
(a) $2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$, $K = 3.4$ at 1000. K
(b) $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$, $K = 9.4 \times 10^{-2}$ at 24°C

10.37 For the reaction $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$ at 400. K, $K = 41$. Find the value of K for each of the following reactions at the same temperature:
(a) $2\ NH_3(g) \rightleftharpoons N_2(g) + 3\ H_2(g)$
(b) $\frac{1}{2}\ N_2(g) + \frac{3}{2}\ H_2(g) \rightleftharpoons NH_3(g)$
(c) $2\ N_2(g) + 6\ H_2(g) \rightleftharpoons 4\ NH_3(g)$

10.38 The equilibrium constant for the reaction $2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$ has the value $K = 2.5 \times 10^{10}$ at 500. K. Find the value of K for each of the following reactions at the same temperature.
(a) $SO_2(g) + \frac{1}{2}\ O_2(g) \rightleftharpoons SO_3(g)$
(b) $SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}\ O_2(g)$
(c) $3\ SO_2(g) + \frac{3}{2}\ O_2(g) \rightleftharpoons 3\ SO_3(g)$

10.39 When 0.0172 mol HI is heated to 500. K in a 2.00-L sealed container, the resulting equilibrium mixture contains 1.90 g of HI. Calculate K for the decomposition reaction $2\ HI(g) \rightleftharpoons H_2(g) + I_2(g)$.

10.40 When 1.00 g of gaseous I_2 is heated to 1000. K in a 1.00-L sealed container, the resulting equilibrium mixture contains 0.830 g of I_2. Calculate K_c for the dissociation equilibrium $I_2(g) \rightleftharpoons 2\ I(g)$.

10.41 A 25.0-g sample of ammonium carbamate, $NH_4(NH_2CO_2)$, was placed in an evacuated 0.250-L flask and kept at 25°C. At equilibrium, 17.4 mg of CO_2 was present. What is the value of K_c for the decomposition of ammonium carbamate into ammonia and carbon dioxide? The reaction is $NH_4(NH_2CO_2)(s) \rightleftharpoons 2\ NH_3(g) + CO_2(g)$.

10.42 Carbon monoxide and water vapor, each at 200. Torr, were introduced into a 250.-mL container. When the mixture reached equilibrium at 700.°C, the partial pressure of $CO_2(g)$ was 88 Torr. Calculate the value of K for the equilibrium $CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$.

10.43 Consider the reaction $2\ NO(g) \rightleftharpoons N_2(g) + O_2(g)$. If the initial partial pressure of NO(g) is 1.0 bar, and x is the equilibrium concentration of $N_2(g)$, what is the correct equilibrium relation? (a) $K = x^2/(1.0 - x)$; (b) $K = x^2$; (c) $K = x^2/(1.0 - 2x)^2$; (d) $K = 4x^3/(1.0 - 2x)^2$; (e) $K = 2x/(1.0 - x)^2$.

10.44 Consider the reaction $2\ NO_2(g) \rightleftharpoons 2\ NO(g) + O_2(g)$. If the initial partial pressure of $NO_2(g)$ is 3.0 bar, and x is the equilibrium concentration of $O_2(g)$, what is the correct equilibrium relation? (a) $K = x^3$; (b) $K = 2x^2/(3.0 - 2x)^2$; (c) $K = 4x^3/(3.0 - 2x)^2$; (d) $K = x^2/(3.0 - x)$; (e) $K = 2x/(3.0 - x)^2$.

10.45 (a) A sample of 2.0 mmol $Cl_2(g)$ was sealed into a 2.0-L reaction vessel and heated to 1000. K to study its dissociation into Cl atoms. Use the information in Table 10.2 to calculate the equilibrium composition of the mixture. (b) If 2.0 mmol F_2 was placed into the reaction vessel instead of the chlorine, what would be its equilibrium composition at 1000. K? (c) Use your results from parts (a) and (b) to determine which is thermodynamically more stable relative to its atoms at 1000. K, Cl_2 or F_2.

10.46 (a) A sample of 5.0 mmol $Cl_2(g)$ was sealed into a 2.0-L reaction vessel and heated to 1200. K, and the dissociation equilibrium was established. What is the equilibrium composition of the mixture? Use the information in Table 10.2. (b) If 5.0 mol Br_2 is placed into the reaction vessel instead of the chlorine, what would be the equilibrium composition at 1200. K? (c) Use your results from parts (a) and (b) to determine which is thermodynamically more stable relative to its atoms at 1200. K, Cl_2, or Br_2.

10.47 For the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$, $K_c = 1.1 \times 10^{-2}$ at 400. K. (a) Given that 1.0 g of PCl_5 is placed in a 250.-mL reaction vessel, determine the molar concentrations in the mixture at equilibrium. (b) What percentage of the PCl_5 has decomposed at equilibrium at 400. K?

10.48 For the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$, $K_c = 0.61$ at 500. K. (a) Calculate the equilibrium molar concentrations of the components in the mixture when 3.6 g of PCl_5 is placed in a 300.-mL reaction vessel and allowed to come to equilibrium. (b) What percentage of the PCl_5 has decomposed at equilibrium at 500. K?

10.49 When solid NH_4HS and 0.400 mol $NH_3(g)$ were placed in a 2.0-L vessel at 24°C, the equilibrium $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$, for which $K_c = 1.6 \times 10^{-4}$, was reached. What are the equilibrium concentrations of NH_3 and H_2S?

10.50 When solid NH_4HS and 0.200 mol $NH_3(g)$ were placed into a 2.0-L vessel at 24°C, the equilibrium $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$, for which $K_c = 1.6 \times 10^{-4}$, was reached. What are the equilibrium concentrations of NH_3 and H_2S?

10.51 The equilibrium constant K_c for the reaction $N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$ at 1200°C is 1.00×10^{-5}. Calculate the equilibrium molar concentrations of NO, N_2, and O_2 in a 1.00-L reaction vessel that initially held 0.114 mol N_2 and 0.114 mol O_2.

10.52 The equilibrium constant K_c for the reaction $N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$ at 1200°C is 1.00×10^{-5}. Calculate the equilibrium molar concentrations of NO, N_2, and O_2 in a 10.00-L reaction vessel that initially held 0.0140 mol N_2 and 0.214 mol O_2.

10.53 A reaction mixture that consisted of 0.400 mol H_2 and 1.60 mol I_2 was introduced into a 3.00-L flask and heated. At equilibrium, 60.0% of the hydrogen gas had reacted. What is the equilibrium constant K for the reaction $H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$ at this temperature?

10.54 A reaction mixture that consisted of 0.20 mol N_2 and 0.20 mol H_2 was introduced into a 25.0-L reactor and heated. At equilibrium, 5.0% of the nitrogen gas had reacted. What is the value of the equilibrium constant K_c for the reaction $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$ at this temperature?

10.55 The equilibrium constant K_c for the reaction $2\ CO(g) + O_2(g) \rightleftharpoons 2\ CO_2(g)$ is 0.66 at 2000.°C. If 0.28 g of CO and 0.032 g of $O_2(g)$ are placed in a 2.0-L reaction vessel and heated to 2000.°C, what will the equilibrium composition of the system be? (You may wish to use graphing software or a calculator to solve the cubic equation.)

10.56 In the Haber process for ammonia synthesis, $K = 0.036$ for $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$ at 500. K. If a 2.0-L reactor is charged with 0.025 bar of N_2 and 0.015 bar of H_2, what will the equilibrium partial pressures in the mixture be?

10.57 At 500. K, the equilibrium constant for the reaction $Cl_2(g) + Br_2(g) \rightleftharpoons 2\ BrCl(g)$ is $K_c = 0.031$. If the equilibrium composition is 0.495 mol·L^{-1} Cl_2 and 0.145 mol·L^{-1} BrCl, what is the equilibrium concentration of Br_2?

10.58 The equilibrium constant for the reaction $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$ is $K = 3.5 \times 10^4$ at 760.°C. At equilibrium, the partial pressure of PCl_5 was 1.3×10^2 bar and that of PCl_3 was 9.56 bar. What was the equilibrium partial pressure of Cl_2?

10.59 A reaction mixture consisting of 2.00 mol CO and 3.00 mol H_2 is placed in a 10.0-L reaction vessel and heated to 1200. K. At equilibrium, 0.478 mol CH_4 was present in the system. Determine the value of K_c for the reaction $CO(g) + 3\ H_2(g) \rightleftharpoons CH_4(g) + H_2O(g)$ at 1200. K.

10.60 A mixture consisting of 1.000 mol $H_2O(g)$ and 1.000 mol CO(g) is placed in a 10.00-L reaction vessel at 800. K. At equilibrium, 0.665 mol $CO_2(g)$ is present as a result of the reaction $CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$. What are (a) the equilibrium concentrations for all substances and (b) the value of K_c at 800. K?

10.61 A reaction mixture is prepared by mixing 0.100 mol SO_2, 0.200 mol NO_2, 0.100 mol NO, and 0.150 mol SO_3 in a 5.00-L reaction vessel. The reaction $SO_2(g) + NO_2(g) \rightleftharpoons NO(g) + SO_3(g)$ is allowed to reach equilibrium at 460.°C, when $K_c = 85.0$. What is the equilibrium concentration of each substance?

10.62 A 0.100-mol sample of H_2S is placed in a 10.0-L reaction vessel and heated to 1132°C. At equilibrium, 0.0285 mol H_2 is present. Calculate the value of K_c for the reaction $2\ H_2S(g) \rightleftharpoons 2\ H_2(g) + S_2(g)$ at 1132°C.

10.63 The equilibrium constant $K_c = 0.56$ for the reaction $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$ at 250.°C. On analysis, 1.50 mol PCl_5, 3.00 mol PCl_3, and 0.500 mol Cl_2 were found to be present in a 0.500-L reaction vessel at 250.°C. (a) Is the reaction at equilibrium? (b) If not, in which direction does it tend to proceed? (c) What is the equilibrium composition of the reaction system?

10.64 An 0.865-mol sample of PCl_5 is placed in a 500.-mL reaction vessel. What is the concentration of each substance when the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$ has reached equilibrium at 250°C (when $K_c = 1.80$)?

10.65 At 25°C, $K = 3.2 \times 10^{-34}$ for the reaction $2\ HCl(g) \rightleftharpoons H_2(g) + Cl_2(g)$. If a 1.0-L reaction vessel is filled with HCl at 0.22 bar, what are the equilibrium partial pressures of HCl, H_2, and Cl_2?

10.66 If 4.00 L of HCl(g) at 1.00 bar and 273 K and 26.0 g of I_2(s) are transferred to a 12.00-L reaction vessel and heated to 25°C, what will the equilibrium concentrations of HCl, HI, and Cl_2 be? $K_c = 1.6 \times 10^{-34}$ at 25°C for 2 HCl(g) + I_2(s) $\rightleftharpoons$ 2 HI(g) + Cl_2(g).

10.67 A 3.00-L reaction vessel is filled with 0.342 mol CO, 0.215 mol H_2, and 0.125 mol CH_3OH. Equilibrium is reached in the presence of a zinc oxide-chromium(III) oxide catalyst and, at 300.°C, $K_c = 1.1 \times 10^{-2}$ for the reaction CO(g) + 2 H_2(g) $\rightleftharpoons$ CH_3OH(g). (a) As the reaction approaches equilibrium, will the concentration of CH_3OH increase, decrease, or remain unchanged? (b) What is the equilibrium composition of the mixture?

10.68 For the reaction 2 NH_3(g) $\rightleftharpoons$ N_2(g) + 3 H_2(g), $K_c = 0.395$ at 350.°C. A 25.6-g sample of NH_3 is placed in a 5.00-L reaction vessel and heated to 350.°C. What are the equilibrium concentrations of NH_3, N_2, and H_2?

10.69 The reaction 2 HCl(g) $\rightleftharpoons$ H_2(g) + Cl_2(g) has $K = 3.2 \times 10^{-34}$ at 298 K. The initial partial pressures are H_2, 1.0 bar; HCl, 2.0 bar; and Cl_2, 3.0 bar. At equilibrium there is 1.0 mol H_2(g). What is the volume of the container? (*Don't be surprised at the large size of the volume.*)

10.70 Suppose that, in the same reaction as in Exercise 10.69, the total pressure at equilibrium is found to be 3.0 bar and the Cl:H atom ratio is 1:3. What are the partial pressures of the three gases?

The Response of Equilibria to Changes in Conditions

10.71 Consider the equilibrium CO(g) + H_2O(g) $\rightleftharpoons$ CO_2(g) + H_2(g). (a) If the partial pressure of CO_2 is increased, what happens to the partial pressure of H_2? (b) If the partial pressure of CO is decreased, what happens to the partial pressure of CO_2? (c) If the concentration of CO is increased, what happens to the concentration of H_2? (d) If the concentration of H_2O is decreased, what happens to the equilibrium constant for the reaction?

10.72 Consider the equilibrium CH_4(g) + 2 O_2(g) $\rightleftharpoons$ CO_2(g) + 2 H_2O(g). (a) If the partial pressure of CO_2 is increased, what happens to the partial pressure of CH_4? (b) If the partial pressure of CH_4 is decreased, what happens to the partial pressure of CO_2? (c) If the concentration of CH_4 is increased, what happens to the equilibrium constant for the reaction? (d) If the concentration of H_2O is decreased, what happens to the concentration of CO_2?

10.73 The four gases NH_3, O_2, NO, and H_2O are mixed in a reaction vessel and allowed to reach equilibrium in the reaction 4 NH_3(g) + 5 O_2(g) $\rightleftharpoons$ 4 NO(g) + 6 H_2O(g). Certain changes (see the following table) are then made to this mixture. Considering each change separately, state the effect (increase, decrease, or no change) that the change has on the original equilibrium values of the quantity in the second column (or *K*, if that is specified). The temperature and volume are constant.

Change	Quantity
(a) add NO	amount of H_2O
(b) add NO	amount of O_2
(c) remove H_2O	amount of NO
(d) remove O_2	amount of NH_3
(e) add NH_3	*K*
(f) remove NO	amount of NH_3
(g) add NH_3	amount of O_2

10.74 The four substances HCl, I_2, HI, and Cl_2 are mixed in a reaction vessel and allowed to reach equilibrium in the reaction 2 HCl(g) + I_2(s) $\rightleftharpoons$ 2 HI(g) + Cl_2(g). Certain changes (which are specified in the first column in the following table) are then made to this mixture. Considering each change separately, state the effect (increase, decrease, or no change) that the change has on the original equilibrium value of the quantity in the second column (or *K*, if that is specified). The temperature and volume are constant.

Change	Quantity
(a) add HCl	amount of HI
(b) add I_2	amount of Cl_2
(c) remove HI	amount of Cl_2
(d) remove Cl_2	amount of HCl
(e) add HCl	*K*
(f) remove HCl	amount of I_2
(g) add I_2	*K*

10.75 State whether reactants or products will be favored by an increase in the total pressure (resulting from compression) on each of the following equilibria. If there is no change, explain why that is so.
(a) 2 O_3(g) $\rightleftharpoons$ 3 O_2(g)
(b) H_2O(g) + C(s) $\rightleftharpoons$ H_2(g) + CO(g)
(c) 4 NH_3(g) + 5 O_2(g) $\rightleftharpoons$ 4 NO(g) + 6 H_2O(g)
(d) 2 HD(g) $\rightleftharpoons$ H_2(g) + D_2(g)
(e) Cl_2(g) $\rightleftharpoons$ 2 Cl(g)

10.76 State what happens to the concentration of the indicated substance when the total pressure on each of the following equilibria is increased (by compression):
(a) NO_2(g) in 2 $Pb(NO_3)_2$(s) $\rightleftharpoons$ 2 PbO(s) + 4 NO_2(g) + O_2(g)
(b) NO(g) in 3 NO_2(g) + H_2O(l) $\rightleftharpoons$ 2 HNO_3(aq) + NO(g)
(c) HI(g) in 2 HCl(g) + I_2(s) $\rightleftharpoons$ 2 HI(g) + Cl_2(g)
(d) SO_2(g) in 2 SO_2(g) + O_2(g) $\rightleftharpoons$ 2 SO_3(g)
(e) NO_2(g) in 2 NO(g) + O_2(g) $\rightleftharpoons$ 2 NO_2(g)

10.77 Consider the equilibrium 3 NH_3(g) + 5 O_2(g) $\rightleftharpoons$ 4 NO(g) + 6 H_2O(g). (a) What happens to the partial pressure of NH_3 when the partial pressure of NO is increased? (b) Does the partial pressure of O_2 decrease when the partial pressure of NH_3 is decreased?

10.78 Consider the equilibrium 2 SO_2(g) + O_2(g) $\rightleftharpoons$ 2 SO_3(g). (a) What happens to the partial pressure of SO_3 when the partial pressure of SO_2 is decreased? (b) If the partial pressure of SO_2 is increased, what happens to the partial pressure of O_2?

10.79 Predict whether each of the following equilibria will shift toward products or reactants with a temperature increase:
(a) N_2O_4(g) $\rightleftharpoons$ 2 NO_2(g), $\Delta H° = +57$ kJ
(b) X_2(g) $\rightleftharpoons$ 2 X(g), where X is a halogen
(c) Ni(s) + 4 CO(g) $\rightleftharpoons$ $Ni(CO)_4$(g), $\Delta H° = -161$ kJ
(d) CO_2(g) + 2 NH_3(g) $\rightleftharpoons$ $CO(NH_2)_2$(s) + H_2O(g), $\Delta H° = -90$ kJ

10.80 Predict whether each of the following equilibria will shift toward products or reactants with a temperature increase:
(a) CH_4(g) + H_2O(g) $\rightleftharpoons$ CO(g) + 3 H_2(g), $\Delta H° = +206$ kJ
(b) CO(g) + H_2O(g) $\rightleftharpoons$ CO_2(g) + H_2(g), $\Delta H° = -41$ kJ
(c) 2 SO_2(g) + O_2(g) $\rightleftharpoons$ 2 SO_3(g), $\Delta H° = -198$ kJ

10.81 A reactor for the production of ammonia by the Haber process is found to be at equilibrium with $P_{N_2} = 3.11$ bar, $P_{H_2} = 1.64$ bar, and $P_{NH_3} = 23.72$ bar. If the partial pressure of N_2 is increased by 1.57 bar, what will be the partial pressure of each gas once equilibrium is re-established?

10.82 In a laboratory studying the extraction of iron metal from iron ore, the following reaction was carried out at 1270 K in a

reaction vessel of volume 10.0 L: $FeO(s) + CO(g) \rightleftharpoons Fe(s) + CO_2(g)$. At equilibrium the partial pressure of CO was 4.24 bar and that of CO_2 was 1.71 bar. The pressure of the CO_2 was reduced to 0.62 bar by reacting some of it with NaOH and the system was allowed to reach equilibrium again. What will be the partial pressure of each gas once equilibrium is re-established?

10.83 A reaction used in the production of gaseous fuels from coal, which is mainly carbon, is $C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$. (a) Evaluate K At 900 K, given that the standard Gibbs free energies of formation of CO(g) and $H_2O(g)$ at 900 K are $-191.28\ kJ{\cdot}mol^{-1}$ and $-198.08\ kJ{\cdot}mol^{-1}$, respectively. (b) A 5.20-kg sample of graphite and 125 g of water were placed into a 10.0-L container and heated to 900 K. What are the equilibrium concentrations?

10.84 The volume of the container used for the reaction in Exercise 10.83 is expanded to 20.0 L and equilibrium was re-established. (a) Without doing a calculation, predict whether the equilibrium concentration of H_2 will have increased or decreased and explain how you decided. (b) Calculate the new equilibrium concentrations and evaluate your prediction. (c) To maximize the production of H_2, should the reaction be run at low or high pressures? At a low or high temperature? Justify your answers.

10.85 A gaseous mixture consisting of 2.23 mmol N_2 and 6.69 mmol H_2 in a 500.-mL container was heated to 600. K and allowed to reach equilibrium. Will more ammonia be formed if that equilibrium mixture is then heated to 700. K? For $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$, $K = 1.7 \times 10^{-3}$ at 600. K and 7.8×10^{-5} at 700. K.

10.86 A gaseous mixture consisting of 1.1 mmol SO_2 and 2.2 mmol O_2 in a 250-mL container was heated to 500. K and allowed to reach equilibrium. Will more sulfur trioxide be formed if that equilibrium mixture is cooled to 298 K? For the reaction $2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$, $K = 2.5 \times 10^{10}$ at 500. K and 4.0×10^{24} at 298 K.

10.87 At 500.°C, $K_c = 0.061$ for $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$. If analysis shows that the composition is $3.00\ mol{\cdot}L^{-1}\ N_2$, $2.00\ mol{\cdot}L^{-1}\ H_2$, and $0.500\ mol{\cdot}L^{-1}\ NH_3$, is the reaction at equilibrium? If not, in which direction does the reaction tend to proceed to reach equilibrium?

10.88 At 2500. K, the equilibrium constant is $K_c = 20.$ for the reaction $Cl_2(g) + F_2(g) \rightleftharpoons 2\ ClF(g)$. An analysis of a reaction vessel at 2500. K revealed the presence of $0.18\ mol{\cdot}L^{-1}\ Cl_2$, $0.31\ mol{\cdot}L^{-1}\ F_2$, and $0.92\ mol{\cdot}L^{-1}$ ClF. Will ClF tend to form or to decompose as the reaction proceeds toward equilibrium?

10.89 Calculate the equilibrium constant at 25°C and at 150.°C for each of the following reactions, using data available in Appendix 2A:
(a) $NH_4Cl(s) \rightleftharpoons NH_3(g) + HCl(g)$
(b) $H_2(g) + D_2O(l) \rightleftharpoons D_2(g) + H_2O(l)$

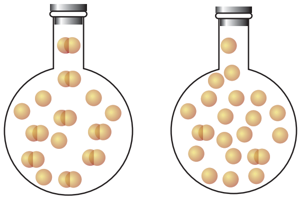
10.90 Calculate the equilibrium constant at 25°C and at 100.°C for each of the following reactions, using data available in Appendix 2A:
(a) $HgO(s) \rightleftharpoons Hg(l) + O_2(g)$
(b) propene (C_3H_6, g) $\rightleftharpoons$ cyclopropane (C_3H_6, g)

10.91 By combining the relation for K_c in terms of K with the van 't Hoff equation, find the analog of the van 't Hoff equation for K_c.

10.92 The vaporization of a liquid can be treated as a special case of an equilibrium. How does the vapor pressure of a liquid vary with temperature? *Hint*: Devise a version of the van't Hoff equation that applies to vapor pressure by first writing the equilibrium constant K for vaporization.

Integrated Exercises

10.93 Dissociation of a diatomic molecule, $X_2(g) \rightleftharpoons 2\ X(g)$ occurs at 500 K. Picture 1 shows the equilibrium state of the dissociation and picture 2 shows the equilibrium state in the same container after a change has occurred. Which of the following changes will produce the change shown? (a) Increasing the temperature. (b) Adding X atoms. (c) Decreasing the volume. (d) Adding a catalyst. Explain your selections.



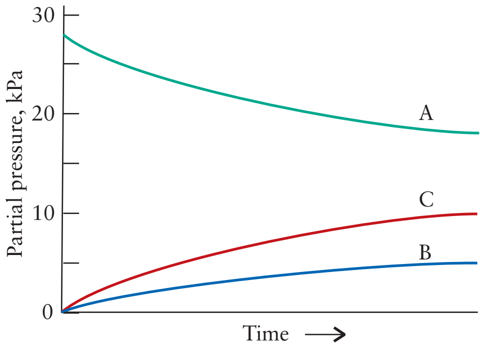
1 2

10.94 At 25°C, $K = 47.9$ for $N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$. (a) If 0.020 mol of N_2O_4 and 0.010 mol of NO_2 are placed in a 2.00-L reaction vessel and the reaction is allowed to reach equilibrium, what are the equilibrium concentrations of N_2O_4 and NO_2? (b) An additional 0.010 mol of NO_2 is added to the flask. How will this change affect the concentration of N_2O_4? (c) Justify your conclusion by calculating the new equilibrium concentrations of NO_2 and N_2O_4.

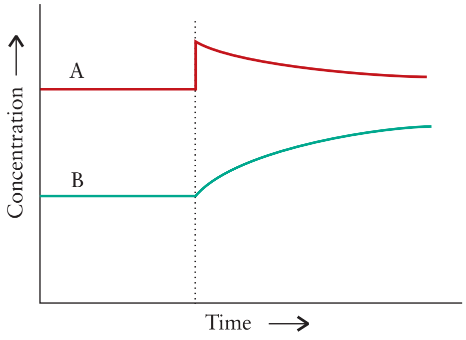
10.95 The overall photosynthesis reaction is $6\ CO_2(g) + 6\ H_2O(l) \longrightarrow C_6H_{12}O_6(aq) + 6\ O_2(g)$, and $\Delta H° = +2802$ kJ. Suppose that the reaction is at equilibrium. State the effect that each of the following changes will have on the equilibrium composition (tends to shift toward the formation of reactants, tends to shift toward the formation of products, or has no effect). (a) The partial pressure of O_2 is increased. (b) The system is compressed. (c) The amount of CO_2 is increased. (d) The temperature is increased. (e) Some of the $C_6H_{12}O_6$ is removed. (f) Water is added. (g) The partial pressure of CO_2 is decreased.

10.96 A certain enzyme-catalyzed reaction in a biochemical cycle has an equilibrium constant that is 10 times the equilibrium constant of the next step in the cycle. If the standard Gibbs free energy of the first reaction is $-200.\ kJ{\cdot}mol^{-1}$, what is the standard Gibbs free energy of the second reaction?

10.97 The following plot shows how the partial pressures of reactant and products vary with time for the decomposition of compound A into compounds B and C. All three compounds are gases. Use this plot to do the following: (a) Write a balanced chemical equation for the reaction. (b) Calculate the equilibrium constant for the reaction. (c) Calculate the value of K_c for the reaction at 25°C.



10.98 The following plot shows a system composed of compounds A and B in a rigid, constant-volume flask. The system was initially at equilibrium, then a change occurred. (a) Describe the change that occurred and how it affected the system. (b) Write the chemical equation for the reaction that occurred. (c) Calculate the value of K for the reaction.



10.99 At 1565 K, the equilibrium constants for the reactions (1) $2\ H_2O(g) \rightleftharpoons 2\ H_2(g) + O_2(g)$ and (2) $2\ CO_2(g) \rightleftharpoons 2\ CO(g) + O_2(g)$ are 1.6×10^{-11} and 1.3×10^{-10}, respectively. (a) What is the equilibrium constant for the reaction (3) $CO_2(g) + H_2(g) \rightleftharpoons H_2O(g) + CO(g)$ at that temperature? (b) Show that the manner in which equilibrium constants are calculated is consistent with the manner in which the $\Delta G_r°$ values are calculated when combining two or more equations by determining $\Delta G_r°$ for reactions (1) and (2) and using those values to calculate $\Delta G_r°$ and K_3 for reaction (3).

10.100 1.50 mol NH_3 decomposed in the reaction $2\ NH_3(g) \rightleftharpoons N_2(g) + 3\ H_2(g)$ in a 1.0-L flask at a certain temperature. At equilibrium, 0.20 mol NH_3 remains. (a) Calculate K for the reaction. (b) Use the information in Table 10.2 to estimate the temperature at which the reaction occurred.

10.101 0.020 mol NO_2 was introduced into a 1.00-L flask and the reaction $2\ NO_2(g) \rightleftharpoons N_2O_4(g)$ was allowed to come to equilibrium at 298 K. (a) Using information in Table 10.2 calculate the equilibrium concentrations of the two gases. (b) The volume of the flask is reduced to half its original volume. Calculate the new equilibrium concentrations of the gases.

10.102 0.100 mol SO_3 was introduced into a 2.00-L flask and the reaction $2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$ was allowed to come to equilibrium at 700 K. (a) Using information in Table 10.2 calculate the equilibrium concentrations of the three gases. (b) The volume of the flask is increased to 6.00-L. Calculate the new equilibrium concentrations of the gases.

10.103 Let α be the fraction of PCl_5 molecules that have decomposed to PCl_3 and Cl_2 in the reaction $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$ in a constant-volume container; then the amount of PCl_5 at equilibrium is $n(1 - \alpha)$, where n is the amount present initially. Derive an equation for K in terms of α and the total pressure P, and solve it for α in terms of P. Calculate the fraction decomposed at 556 K, at which temperature $K = 4.96$, and the total pressure is (a) 0.50 bar; (b) 1.00 bar.

10.104 The three compounds methylpropene, *cis*-2-butene, and *trans*-2-butene are isomers with formula C_4H_8, with $\Delta G_f° = +58.07$, $+65.86$, and $+62.97\ kJ{\cdot}mol^{-1}$, respectively. In the presence of a suitable metal catalyst, these three compounds can be interconverted to give an equilibrium gaseous mixture. What will be the percentage of each isomer present at 25°C once equilibrium is established?

10.105 (a) What is the standard Gibbs free energy of the reaction $CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$ when $K = 1.00$? (b) From data available in Appendix 2A, estimate the temperature at which $K = 1.00$. (c) At this temperature, a cylinder is filled with CO(g) at 10.00 bar, $H_2O(g)$ at 10.00 bar, $H_2(g)$ at 5.00 bar, and $CO_2(g)$ at 5.00 bar. What will be the partial pressure of each of these gases when the system reaches equilibrium? (d) If the cylinder were filled instead with CO(g) at 6.00 bar, $H_2O(g)$ at 4.00 bar, $H_2(g)$ at 5.00 bar, and $CO_2(g)$ at 10.00 bar, what would the partial pressures be at equilibrium?

10.106 Consider the equilibrium $A(g) \rightleftharpoons 2\ B(g) + 3\ C(g)$ at 25°C. When A is loaded into a cylinder at 10.0 atm and the system is allowed to come to equilibrium, the final pressure is found to be 15.76 atm. What is $\Delta G_r°$ for this reaction?

10.107 (a) Calculate the Gibbs free energies of formation of the halogen atoms X(g) at 1000. K from data available in Table 10.2. (b) Show how these data correlate with the X—X bond strength by plotting the Gibbs free energy of formation of the atoms against the bond dissociation energy and atomic number. Rationalize any trends you observe.

10.108 The gas phosphine, PH_3, decomposes by the reaction $2\ PH_3(g) \longrightarrow 2\ P(s) + 3\ H_2(g)$. In an experiment, pure phosphine was placed in a rigid, sealed 1.00-L flask at 0.64 bar and 298 K. After equilibrium was attained, the total pressure in the flask was found to be 0.93 bar. (a) Calculate the equilibrium partial pressures of H_2 and PH_3. (b) Calculate the mass (in grams) of P produced once equilibrium was reached. (c) Calculate K for this reaction.

10.109 (a) Calculate K at 25°C for the reaction $Br_2(g) \rightleftharpoons 2\ Br(g)$ from the thermodynamic data provided in Appendix 2A. (b) What is the vapor pressure of liquid bromine? (c) What is the partial pressure of Br(g) above the liquid in a bottle of bromine at 25°C? (d) A student wishes to add 0.0100 mol Br_2 to a reaction and will do so by filling an evacuated flask with Br_2 vapor from a reservoir that contains only bromine liquid in equilibrium with its vapor. The flask will be sealed and then transferred to the reaction vessel. What volume container should the student use to deliver 0.010 mol $Br_2(g)$ at 25°C?

10.110 A reaction vessel is filled with $Cl_2(g)$ at 1.00 bar and $Br_2(g)$ at 1.00 bar, which are allowed to react at 1000. K to form BrCl(g) according to the equation $Br_2(g) + Cl_2(g) \rightleftharpoons 2\ BrCl(g)$, $K = 0.2$. Construct a plot of the Gibbs free energy of this system as a function of partial pressure of BrCl as the reaction approaches equilibrium.

10.111 The Claus process, which is used to remove sulfur found as sulfur dioxide in petroleum, is based on the reaction $2\ H_2S(g) + SO_2(g) \rightleftharpoons 3\ S(s) + 2\ H_2O(g)$. (a) Use data from Appendix 2A to determine the equilibrium constant of this reaction at 25°C. (b) Certain changes (see the following table) are then made to this mixture. Considering each change separately, state the effect (increase, decrease, or no change) that the change has on the original equilibrium values of the quantity in the second column

(or K, if that is specified). The temperature and volume are constant unless otherwise specified.

Change	Quantity
(a) add S	amount of H_2O
(b) add H_2S	amount of SO_2
(c) remove H_2O	amount of SO_2
(d) remove SO_2	amount of S
(e) add SO_2	K
(f) decrease volume	amount of SO_2
(g) increase temperature	amount of SO_2

10.112 Using data from Table 10.2 and standard graphing software, determine the enthalpy and entropy of the equilibrium $N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$ and estimate the N—N bond enthalpy in N_2O_4. How does this value compare with the mean N—N bond enthalpy in Table 7.8?

10.113 The distribution of Na^+ ions across a typical biological membrane is 10. $mmol{\cdot}L^{-1}$ inside the cell and 140 $mmol{\cdot}L^{-1}$ outside the cell. At equilibrium the concentrations would be equal, but in a living cell the ions are not at equilibrium. What is the Gibbs free energy difference for Na^+ ions across the membrane at 37°C (normal body temperature)? The concentration differential must be maintained by coupling to reactions that have at least that difference of Gibbs free energy.

10.114 ATP is a compound that provides energy for biochemical reactions in the body when it undergoes hydrolysis. For the hydrolysis of ATP at 37°C (normal body temperature) $\Delta H_r° = -20.\ kJ{\cdot}mol^{-1}$ and $\Delta S_r° = +34\ J{\cdot}K^{-1}{\cdot}mol^{-1}$. Assuming that these quantities are independent of temperature, calculate the temperature at which the equilibrium constant for the hydrolysis of ATP becomes greater than 1.

10.115 The reaction $N_2O_4 \rightleftharpoons 2\ NO_2$ is allowed to reach equilibrium in chloroform solution at 25°C. The equilibrium concentrations are 0.405 $mol{\cdot}L^{-1}$ N_2O_4 and 2.13 $mol{\cdot}L^{-1}$ NO_2. (a) Calculate K for the reaction. (b) An additional 1.00 mol NO_2 is added to 1.00 L of the solution and the system is allowed to reach equilibrium again at the same temperature. Use Le Chatelier's principle to predict the direction of change (increase, decrease, or no change) for N_2O_4, NO_2, and K_c after the addition of NO_2. (c) Calculate the final equilibrium concentrations after the addition of NO_2 and confirm that your predictions in part (b) were valid. If they do not agree, check your procedure and repeat it if necessary.

10.116 In order to generate the starting material for a polymer that is used in water bottles, hydrogen is removed from the ethane in natural gas to produce ethene in the catalyzed reaction $C_2H_6(g) \rightleftharpoons H_2(g) + C_2H_4(g)$. Use the information in Appendix 2A to calculate the equilibrium constant for the reaction at 298 K. (a) If the reaction is begun by adding the catalyst to a flask containing C_2H_6 at 10.0 bar, what will be the partial pressure of the C_2H_4 at equilibrium? (b) Identify three steps the manufacturer can take to increase the yield of product.

10.117 Determine the vapor pressure of heavy water, D_2O, and of normal water at 25°C by using data in Appendix 2A. How do these values compare with each other? Using your knowledge of intermolecular forces, explain the reason for the difference observed.

10.118 A chemist needs to prepare the compound PH_3BCl_3 by using the reaction $PH_3(g) + BCl_3(g) \longrightarrow PH_3BCl_3(s)$ for which $K = 19.2$ at 60.°C. (a) Write the expression for K. (b) What is the value of K_c for this reaction? (c) Some solid PH_3BCl_3 was added to a closed 500.-mL vessel at 60.°C that already contains 0.0128 mol PH_3. What is the equilibrium concentration of PH_3? (d) At 70.°C, $K = 26.2$. Is the reaction endothermic or exothermic? Explain your reasoning. (e) What is the new value of K_c? (f) Can the reactants in the preceding reaction be classified as acids or bases? Explain your answer.

10.119 It is possible to choose a different standard state (after all, molecules don't know what their standard state is) for the pressure or concentration of chemical species. The standard state corresponding to data presented in Appendix 2A is for 1 bar or 1 M, as appropriate. Calculate $\Delta G_f°$ for each of the following species if the standard state condition were changed to that listed (the temperature remains at 298 K):
(a) HI(g), standard state corresponds to 1 atm
(b) CO(g), standard state corresponds to 1 atm
(c) HCN(g), standard state corresponds to 1 Torr
(d) $CH_4(g)$, standard state corresponds to 1 Pa

10.120 Cyclohexane (C) and methylcyclopentane (M) are isomers with the chemical formula C_6H_{12}. The equilibrium constant for the rearrangement $C \rightleftharpoons M$ in solution is 0.140 at 25°C. (a) A solution of 0.0200 $mol{\cdot}L^{-1}$ cyclohexane and 0.100 $mol{\cdot}L^{-1}$ methylcyclopentane is prepared. Is the system at equilibrium? If not, will it will form more reactants or more products? (b) What are the concentrations of cyclohexane and methylcyclohexane at equilibrium? (c) If the temperature is raised to 50.°C, the concentration of cyclohexane becomes 0.100 $mol{\cdot}L^{-1}$ when equilibrium is re-established. Calculate the new equilibrium constant. (d) Is the reaction exothermic or endothermic at 25°C? Explain your conclusion.

10.121 Use the Living Graph "Variation of Equilibrium Constant" on the Web site for this book to construct a plot from 250 K to 350 K for reactions with standard reaction Gibbs free energies of $+11\ kJ{\cdot}mol^{-1}$ to $+15\ kJ{\cdot}mol^{-1}$ in increments of $1\ kJ{\cdot}mol^{-1}$. Which equilibrium constant is most sensitive to changes in temperature?

10.122 (a) Use graphing software, such as that found on the Web site for this book, and data at 1000. K and 1200. K from Table 10.2, to plot the van 't Hoff equations for the dissociation of the diatomic halogens into the atoms, $X_2(g) \rightleftharpoons 2\ X(g)$. (b) From the graphs, determine the enthalpies and entropies of dissociation. (c) Use these data to calculate the molar entropies of the gaseous halogen atoms X(g).

10.123 The two air pollutants SO_3 and NO can react in the atmosphere as follows: $SO_3(g) + NO(g) \longrightarrow SO_2(g) + NO_2(g)$. (a) Predict the effect of the following changes to the amount of NO_2 when the reaction has come to equilibrium in a stainless steel bulb equipped with entrants for chemicals: (i) the amount of NO is increased; (ii) the SO_2 is removed by condensation; (iii) the pressure is tripled by pumping in helium. (b) Given that at a certain temperature $K = 6.0 \times 10^3$, calculate the amount (in moles) of NO that must be added to a 1.00-L vessel containing 0.245 mol $SO_3(g)$ to form 0.240 mol $SO_2(g)$ at equilibrium.

Chemistry Connections

10.124 Reactions between gases in the atmosphere are not at equilibrium, but for a thorough understanding of them we need to

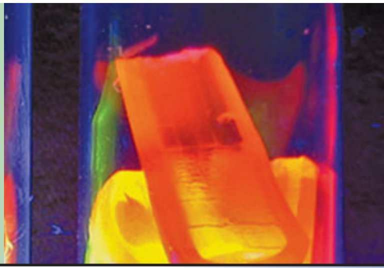
study both the rates at which they take place and their behavior under equilibrium conditions.
(a) The equilibrium for the depletion of ozone in the stratosphere is summarized by the equation $2\ O_3(g) \rightleftharpoons 3\ O_2(g)$. From values in Appendix 2A, determine the standard Gibbs free energy and the standard entropy for the reaction.
(b) What is the equilibrium constant of the reaction in part (a) at 25°C? What is the significance of your answer with regard to ozone depletion?
(c) A reaction that destroys ozone in the stratosphere is $O_3(g) + O(g) \rightleftharpoons 2\ O_2(g)$. Calculate the value of the equilibrium constant for this reaction at 25°C given that at that temperature the reaction is catalyzed (accelerated) by NO_2 molecules in a two-step process:

$$NO_2(g) + O(g) \rightleftharpoons NO(g) + O_2(g) \qquad K = 7 \times 10^{103}$$

$$NO(g) + O_3(g) \rightleftharpoons NO_2(g) + O_2(g) \qquad K = 5.8 \times 10^{-34}$$

(d) Use your answer to part (c) to find the standard Gibbs free energy of formation of O atoms.
(e) The temperature dependence of the equilibrium constant of the reaction $N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$, which makes an important contribution to the concentration of atmospheric nitrogen oxides, can be expressed as $\ln K = 2.5 - (21\ 700\ \text{K})/T$. What is the standard enthalpy of the forward reaction at 298 K? Will this reaction proceed further at the very low temperatures of the stratosphere or at the very high temperatures in an internal combustion engine?
(f) An equimolar mixture of N_2 and O_2 was heated to a certain temperature until the reaction in part (e) came to equilibrium. The equilibrium reaction mixture was found to contain an equal number of moles of each reactant and product. At what temperature was the reaction carried out?
(g) An equimolar mixture of N_2 and O_2 with a total pressure of 4.00 bar was allowed to come to equilibrium in the reaction in part (e) at 1200. K. What will be the partial pressure of each reactant and product at equilibrium?

ACIDS AND BASES



Chapter **11**

THE NATURE OF ACIDS AND BASES
11.1 Brønsted–Lowry Acids and Bases
11.2 Lewis Acids and Bases
11.3 Acidic, Basic, and Amphoteric Oxides
11.4 Proton Exchange Between Water Molecules
11.5 The pH Scale
11.6 The pOH of Solutions
WEAK ACIDS AND BASES
11.7 Acidity and Basicity Constants
11.8 The Conjugate Seesaw
11.9 Molecular Structure and Acid Strength
11.10 The Strengths of Oxoacids and Carboxylic Acids
THE pH OF SOLUTIONS OF WEAK ACIDS AND BASES
11.11 Solutions of Weak Acids
11.12 Solutions of Weak Bases
11.13 The pH of Salt Solutions
POLYPROTIC ACIDS AND BASES
11.14 The pH of a Polyprotic Acid Solution
11.15 Solutions of Salts of Polyprotic Acids
11.16 The Concentrations of Solute Species
11.17 Composition and pH
AUTOPROTOLYSIS AND pH
11.18 Very Dilute Solutions of Strong Acids and Bases
11.19 Very Dilute Solutions of Weak Acids

What Are the Key Ideas? Brønsted acids are proton donors; Brønsted bases are proton acceptors. The composition of a solution of an acid or base immediately adjusts to satisfy the values of the equilibrium constants for all the proton transfer reactions taking place.

Why Do We Need to Know This Material? Chapter 10 developed the concepts of chemical equilibria in gaseous systems; this chapter extends those ideas to aqueous systems, which are important throughout chemistry and biology. Equilibria between acids, bases, and water in plant and animal cells are vital for the survival of individual organisms. To sustain human societies and protect our ecosystems, we also need these ideas to understand the acidity of rain, natural waters such as lakes and rivers, and municipal water supplies.

What Do We Need to Know Already? This chapter builds on the introduction to acids and bases in Section J. It also extends the principles of thermodynamics (Chapters 7 and 8) and chemical equilibrium (Chapter 10) to aqueous systems. To a smaller extent, it uses the concepts of hydrogen bonding (Section 5.5), bond polarity (Section 2.12), and bond strength (Sections 2.14 and 2.15).

Two of the most important classes of compounds in the whole of chemistry are the acids and bases. They are involved in huge numbers of reactions, in laboratory synthetic and analytical procedures, in industry, and in living organisms. It is not much of an exaggeration to say that most of the processes that go on inside our bodies are the reactions of acids and bases: one could take the view that life is one long titration.

In this chapter, we see what acids and bases are and why they vary in strength. We shall use thermodynamics, particularly equilibrium constants, to describe the strengths of acids and bases quantitatively and thereby develop our insight into their behavior. We then use our knowledge of equilibria involving acids and bases to examine systems in which more than one equilibrium is taking place simultaneously, as occurs in many natural systems of ecological and biological importance.

THE NATURE OF ACIDS AND BASES

When chemists see a pattern in the reactions of certain substances, they formulate a definition of a class of substance that captures the pattern. Then, by identifying a substance as belonging to that class, they immediately know a great deal about its behavior. Classification of this kind opens the door to understanding rather than just memorizing the properties of individual substances. The reactions of the substances we call "acids" and "bases" are an excellent illustration of this approach. The pattern in these reactions was first identified in aqueous solutions, and led to the Arrhenius definitions of acids and bases (Section J). However, chemists discovered that similar reactions take place in nonaqueous solutions and even in the absence of solvent. The original definitions had to be replaced by more general definitions that encompassed this new knowledge.

11.1 Brønsted–Lowry Acids and Bases

In 1923, the Danish chemist Johannes Brønsted proposed that

An **acid** is a proton donor.
A **base** is a proton acceptor.

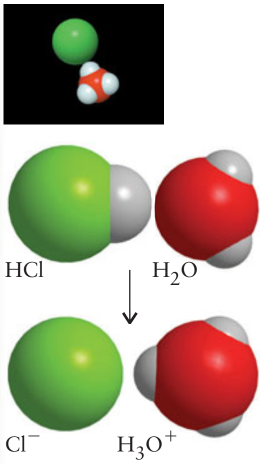


FIGURE 11.1 When an HCl molecule dissolves in water, a hydrogen bond forms between the H atom of HCl (the acid) and the O atom of a neighboring H_2O molecule (the base). The nucleus of the hydrogen atom is pulled out of the HCl molecule to become part of a hydronium ion.

Animation 11.1

The term *proton* in these definitions refers to the hydrogen ion, H^+. An acid is a species containing an **acidic hydrogen atom,** which is a hydrogen atom that can be transferred as its nucleus, a proton, to another species acting as a base. The same definitions were proposed independently by the English chemist Thomas Lowry, and the theory based on them is called the **Brønsted–Lowry theory** of acids and bases. A proton donor is commonly referred to as a **Brønsted acid** and a proton acceptor as a **Brønsted base.** Whenever we refer to an "acid" or a "base" in this chapter, we shall mean a Brønsted acid and a Brønsted base.

A substance can act as an acid only if a base is present to accept its acidic protons. An acid does not simply release its acidic proton: the proton is *transferred* to the base through direct contact. For example, HCl is a Brønsted acid. In the gas phase, an HCl molecule remains intact. However, when HCl dissolves in water, each HCl molecule immediately transfers an H^+ ion to a neighboring H_2O molecule, which here is acting as a base (Fig. 11.1). This process is a **proton transfer reaction,** a reaction in which a proton is transferred from one species to another. We say that the HCl molecule becomes **deprotonated:**

$$HCl(aq) + H_2O(l) \longrightarrow H_3O^+(aq) + Cl^-(aq)$$

Because at equilibrium virtually all the HCl molecules have donated their protons to water, HCl is classified as a *strong acid*. The proton transfer reaction essentially goes to completion. The H_3O^+ ion is called the *hydronium ion*. It is strongly hydrated in solution, and there is some evidence that a better representation of the species is $H_9O_4^+$ (or even larger clusters of water molecules attached to a proton). A hydrogen ion in water is sometimes represented as $H^+(aq)$, but we must remember that H^+ does not exist by itself in water and that H_3O^+ is a better representation because it indicates that a Brønsted base (H_2O) has accepted a proton.

Another example of an acid is hydrogen cyanide, HCN, which transfers its proton to water when it dissolves to form the solution known as hydrocyanic acid, HCN(aq). However, only a small fraction of the HCN molecules donate their protons, and so, as described in Section J, we classify HCN as a *weak acid* in water. We write the proton transfer reaction as an equilibrium:

$$HCN(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CN^-(aq)$$

Like all chemical equilibria, this equilibrium is dynamic and we should think of protons as ceaselessly exchanging between HCN and H_2O molecules, with a constant but low concentration of CN^- and H_3O^+ ions. The proton transfer reaction of a strong acid, such as HCl, in water is also dynamic, but the equilibrium lies so strongly in favor of products that we represent it just by its forward reaction with a single arrow.

In Section J we saw that an Arrhenius acid is a compound that produces hydronium ions in water and an Arrhenius base is a compound that produces hydroxide ions in water. The Brønsted definition is more general because it includes the possibility that an ion is an acid (an option not allowed by the Arrhenius definition). For instance, a hydrogen carbonate ion, HCO_3^-, one of the species present in natural waters, can act as an acid and donate a proton to an H_2O molecule (Fig. 11.2):

$$HCO_3^-(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CO_3^{2-}(aq)$$

FIGURE 11.2 Stalactites hang from the roof of a cave and stalagmites grow from the floor. Both are made of insoluble calcium carbonate formed from the soluble hydrogen carbonate ions in groundwater.

This reaction proceeds to completion if the CO_3^{2-} ions are removed by precipitation with Ca^{2+} ions to form a precipitate of calcium carbonate. In the absence of ions that remove the CO_3^{2-} ions, though, the equilibrium remains strongly in favor of the reactants because a positively charged proton can be removed from the negatively charged HCO_3^- ion only with difficulty.

In the Brønsted–Lowry theory, the strength of an acid depends on the extent to which it donates protons to the solvent. We can therefore summarize the distinction between strong and weak acids as follows:

A **strong acid** is fully deprotonated in solution.
A **weak acid** is only partly deprotonated in solution.

The strength of an acid depends on the solvent and an acid that is strong in water may be weak in another solvent or vice versa (see Section 11.8). However, because almost all reactions in living tissues and most reactions in laboratories take place in water, unless otherwise specified, the solvent used in this chapter is water.

A Brønsted base possesses a lone pair of electrons to which a proton can bond. For example, an oxide ion is a Brønsted base. When CaO dissolves in water, the strong electric field of the small, highly charged O^{2-} ion pulls a proton out of a neighboring H_2O molecule (Fig. 11.3). In the process, a coordinate covalent bond forms between the proton and a lone pair of electrons on the oxide ion. By accepting a proton, the oxide ion has become **protonated.** Every oxide ion present accepts a proton from water, and so O^{2-} is an example of a *strong base* in water, a species that is fully protonated. That is, the following reaction goes essentially to completion:

A coordinate covalent bond is a bond in which both bonding electrons come from the same atom (Section 2.11).

$$O^{2-}(aq) + H_2O(l) \longrightarrow 2\ OH^-(aq)$$

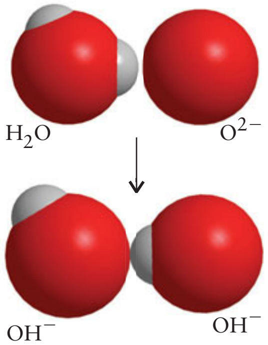

FIGURE 11.3 When an oxide ion is present in water, it exerts such a strong attraction on the nucleus of a hydrogen atom in a neighboring water molecule that the hydrogen ion is pulled out of the molecule as a proton. As a result, the oxide ion forms two hydroxide ions.

Another example of a Brønsted base is ammonia. When an NH_3 molecule is present in water, the lone pair of electrons on the N atom accepts a proton from H_2O:

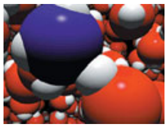
$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

The fact that the NH_3 molecule is electrically neutral means that it has much less proton-pulling power than the oxide ion. As a result, only a very small proportion of the NH_3 molecules are converted into NH_4^+ ions (Fig. 11.4). Ammonia is therefore an example of a *weak base*. All amines, organic derivatives of ammonia, such as methylamine, CH_3NH_2, are weak bases in water. Because the proton transfer equilibrium in an aqueous solution of ammonia is dynamic, we should imagine the protons as ceaselessly exchanging between NH_3 and H_2O molecules with a constant, low concentration of NH_4^+ and OH^- ions. The proton transfer to the strong base O^{2-} is also dynamic, but the equilibrium lies so strongly in favor of products that, as for a strong acid, we represent it just by its forward reaction with a single arrow.

We can summarize the distinction between strong and weak bases as follows:

A **strong base** is completely protonated in solution.
A **weak base** is only partially protonated in solution.

As for acids, the strength of a base depends on the solvent; a base that is strong in water may be weak in another solvent and vice versa. The common strong bases in aqueous solution are listed in Table J.1.



A note on good practice: The oxides and hydroxides of the alkali and alkaline earth metals are not Brønsted bases: the oxide and hydroxide *ions* they contain are the bases (the cations are spectator ions). However, for convenience, and using the Arrhenius definitions, chemists often refer to the compounds themselves as bases.

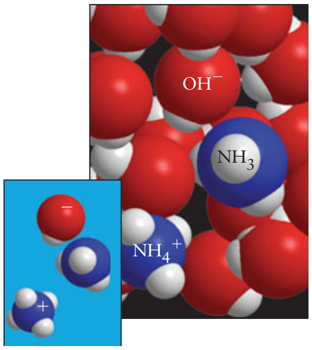


FIGURE 11.4 In this molecular portrayal of the structure of a solution of ammonia in water at equilibrium, we see that NH_3 molecules are still present because only a small percentage of them have been protonated by transfer of hydrogen ions from water. In a typical solution, only about 1 in 100 NH_3 molecules is protonated. The inset at the left shows only the solute species.

Animation 11.4

The species produced by proton transfer in aqueous solution may also donate a proton to or accept a proton from water and thus be classified as an acid or a base. For example, the CN^- ion produced when HCN is deprotonated can accept a proton from a neighboring H_2O molecule and form HCN again. Therefore, according to the Brønsted definition, CN^- is a base: it is called the "conjugate base" of the acid HCN. In general, a **conjugate base** of an acid is the species left when the acid donates a proton:

$$\text{Acid} \xrightarrow{\text{donates } H^+} \text{conjugate base}$$

Because HCN is the acid that forms when a proton is transferred to a cyanide ion, HCN is the "conjugate acid" of the base CN^-. In general, a **conjugate acid** of a base is the species formed when the base accepts a proton:

$$\text{Base} \xrightarrow{\text{accepts } H^+} \text{conjugate acid}$$

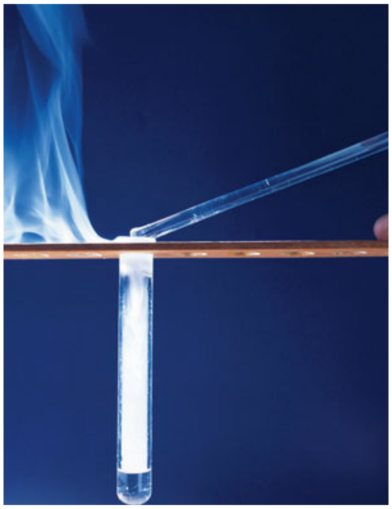

FIGURE 11.5 The white powder is ammonium chloride formed by gaseous ammonia and hydrogen chloride gas escaping from concentrated hydrochloric acid.

EXAMPLE 11.1 **Writing the formulas of conjugate acids and bases**

Write the formulas of (a) the conjugate base of HCO_3^- and (b) the conjugate acid of O^{2-}.

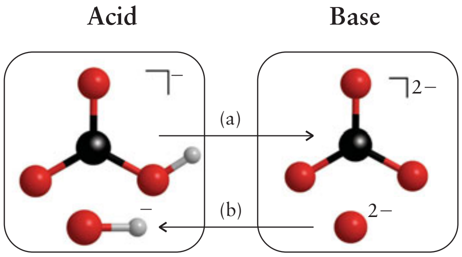
PLAN To proceed systematically, remove an H^+ ion to form a conjugate base and add an H^+ ion to form a conjugate acid.

SOLVE

The conjugate base of an acid has one less H^+ ion than the acid; the conjugate acid of a base has one more H^+ ion than that of the base.

(a) The conjugate base of HCO_3^- is CO_3^{2-}.

(b) The conjugate acid of O^{2-} is OH^-.



Self-Test 11.1A What is (a) the conjugate acid of OH^-; (b) the conjugate base of HPO_4^{2-}?

[*Answer:* (a) H_2O; (b) PO_4^{3-}]

Self-Test 11.1B What is (a) the conjugate acid of H_2O; (b) the conjugate base of NH_3?

The Brønsted definitions of acids and bases also apply to species in nonaqueous solvents and even to gas-phase reactions where there is no solvent. For example, when acetic acid is dissolved in liquid ammonia, proton transfer takes place and the following equilibrium is reached:

$$CH_3COOH(am) + NH_3(l) \rightleftharpoons CH_3CO_2^-(am) + NH_4^+(am)$$

(The label "am" indicates a species dissolved in liquid ammonia.) An example of proton transfer in the gas phase is the reaction of hydrogen chloride and ammonia gases. They produce the fine powder of ammonium chloride often seen coating surfaces in chemical laboratories (Fig. 11.5):

$$HCl(g) + NH_3(g) \longrightarrow NH_4Cl(s)$$

A Brønsted acid is a proton donor and a Brønsted base is a proton acceptor. The conjugate base of an acid is the base formed when the acid has donated a proton. The conjugate acid of a base is the acid that forms when the base has accepted a proton. A strong acid is fully deprotonated in solution; a weak acid is only partially deprotonated in solution. A strong base is completely protonated in solution; a weak base is only partially protonated in solution.

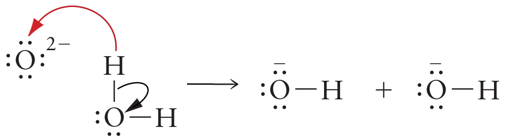
11.2 Lewis Acids and Bases

The Brønsted–Lowry theory focuses on the transfer of a proton from one species to another. However, the concepts of acids and bases have a much wider significance than the transfer of protons. Even more substances can be classified as acids or bases under the definitions developed by G. N. Lewis:

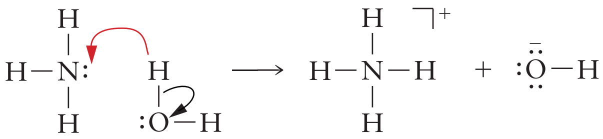
A **Lewis acid** is an electron pair acceptor.
A **Lewis base** is an electron pair donor.

When a Lewis base donates an electron pair to a Lewis acid, the two species share the pair and become joined by a coordinate covalent bond. A proton (H^+) is an electron pair acceptor. It is therefore a Lewis acid because it can attach to ("accept") a lone pair of electrons on a Lewis base. In other words, a Brønsted acid is a *supplier* of one particular Lewis acid, a proton.

The Lewis theory is more general than the Brønsted–Lowry theory. For instance, metal atoms and ions can act as Lewis acids, as in the formation of $Ni(CO)_4$ from nickel atoms (the Lewis acid) and carbon monoxide (the Lewis base), but they are not Brønsted acids. Likewise, a Brønsted base is a special kind of Lewis base, one that can use a lone pair of electrons to form a coordinate covalent bond to a proton. For instance, an oxide ion is a Lewis base. It forms a coordinate covalent bond to a proton, a Lewis acid, by supplying both the electrons for the bond:



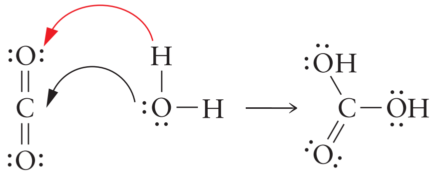
The black curved arrows show the direction in which the electrons can be thought to move; the red curved arrow shows the proton transfer. Similarly, when the Lewis base ammonia, NH_3, dissolves in water, some of the molecules accept protons from water molecules:



The Lewis definition of a base is broader than the Brønsted definition. That is, although every Brønsted base is a Lewis base, not every Lewis base is a Brønsted base. For instance, carbon monoxide is an important Lewis base in its reactions with metals, but it is not a Brønsted base because it does not accept protons.

A note on good practice: The entities that are regarded as acids and bases are different in each theory. In the Lewis theory, the proton is an acid; in the Brønsted theory, the species that *supplies* the proton is the acid. In both the Lewis and Brønsted theories, the species that accepts a proton is a base; in the Arrhenius theory, the compound that *supplies* the proton acceptor is the base (Fig. 11.6).

Many nonmetal oxides are Lewis acids that react with water to give Brønsted acids. An example is the reaction of CO_2 with water:



In this reaction, the C atom of CO_2, the Lewis acid, accepts an electron pair from the O atom of a water molecule, the Lewis base, and a proton migrates from an H_2O oxygen atom to a CO_2 oxygen atom. The product, an H_2CO_3 molecule, is a Brønsted acid.

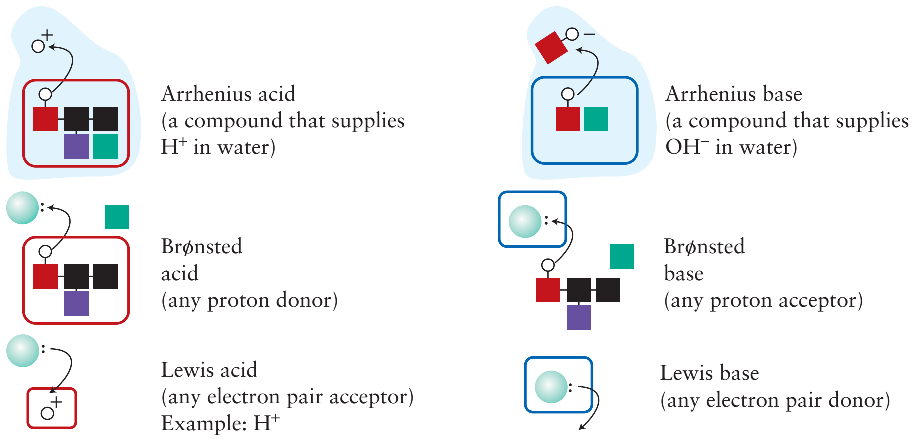


FIGURE 11.6 The left-hand column illustrates the action of acids in the Arrhenius, Brønsted, and Lewis definitions. The right-hand column shows the action of the corresponding bases. In each case the rounded rectangles enclose the acid or base and the small white circles represent hydrogen ions. The green square represents an accompanying ion. The Arrhenius definition includes any accompanying ion, whereas the Brønsted definition may apply either to a compound or, as here, to an ion. Notice that only the Arrhenius definition requires the presence of water (the blue background).

Although the Lewis definitions are natural extensions of the Brønsted definitions, they are too broad for most of our present purposes. Because proton transfer plays a very special role in chemistry we shall focus on it in the rest of the chapter. However, in Chapter 16 we shall see that the Lewis definitions do have a very important role to play and they will then move to center stage.

Self-Test 11.2A Identify (a) the Brønsted acids and bases in both reactants and products in the proton transfer equilibrium $HNO_2(aq) + HPO_4^{2-}(aq) \rightleftharpoons NO_2^-(aq) + H_2PO_4^-(aq)$. (b) Which species (not necessarily shown explicitly) are Lewis acids and which are Lewis bases?

[***Answer:*** (a) Brønsted acids, HNO_2, $H_2PO_4^-$; Brønsted bases, HPO_4^{2-} and NO_2^-; (b) Lewis acid, H^+; Lewis bases, HPO_4^{2-} and NO_2^-]

Self-Test 11.2B Identify (a) the Brønsted acids and bases in both reactants and products in the proton transfer equilibrium $HCO_3^-(aq) + NH_4^+(aq) \rightleftharpoons H_2CO_3(aq) + NH_3(aq)$. (b) Which species (not necessarily shown explicitly) are Lewis acids and which are Lewis bases?

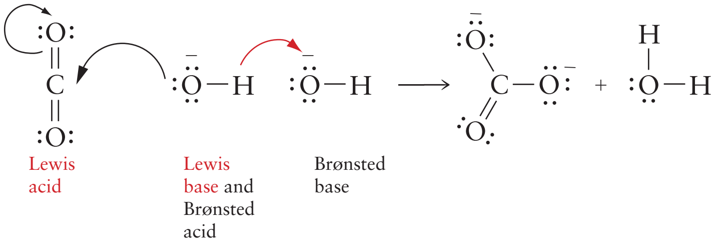
A Lewis acid is an electron pair acceptor; a Lewis base is an electron pair donor. A proton is a Lewis acid that attaches to a lone pair provided by a Lewis base.

11.3 Acidic, Basic, and Amphoteric Oxides

An **acidic oxide** is an oxide that reacts with water to form a solution of a Brønsted acid: an example is CO_2, which forms H_2CO_3, as we saw in Section 11.2. Acidic oxides are *molecular* compounds, such as CO_2, which are Lewis acids that react with bases. Carbon dioxide, for instance, reacts with the OH^- present in aqueous sodium hydroxide:

$$2\,NaOH(aq) + CO_2(g) \longrightarrow Na_2CO_3(aq) + H_2O(l)$$

We can glimpse the underlying complexity of this apparently simple reaction by noting that it involves the attack on CO_2 of OH^- acting as a Lewis base and proton transfer to another OH^- ion acting as a Brønsted base (although these processes are being shown together here, they do not take place in one step):



The white crust often seen on pellets of sodium hydroxide is a mixture of sodium carbonate formed in this way and of sodium hydrogen carbonate formed in a similar reaction:

$$NaOH(aq) + CO_2(g) \longrightarrow NaHCO_3(aq)$$

A **basic oxide** is an oxide that reacts with water to form a solution of hydroxide ions, as in the reaction

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq)$$

Basic oxides are *ionic* compounds that can react with acids to give a salt and water. For instance, magnesium oxide, a basic oxide, reacts with hydrochloric acid:

$$MgO(s) + 2\,HCl(aq) \longrightarrow MgCl_2(aq) + H_2O(l)$$

In this reaction, the base O^{2-} accepts two protons from the hydronium ions present in the hydrochloric acid solution.

Metals typically form basic oxides and nonmetals typically form acidic oxides, but what about the elements that lie on the diagonal frontier between the metals and nonmetals? Along this frontier, from beryllium to polonium, metallic character blends into nonmetallic character and the oxides of these elements have both acidic and basic

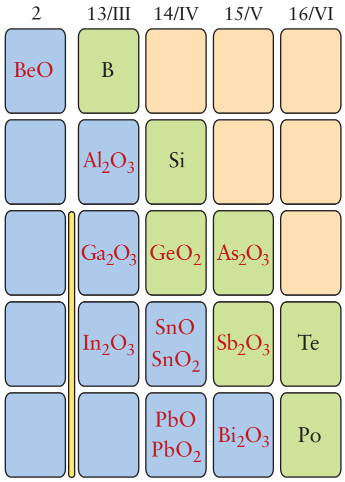


FIGURE 11.7 The elements in and close to the diagonal line of metalloids typically form amphoteric oxides (indicated by the red lettering).

3	4	5	6	7	8	9	10	11	12
Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn
3	4	4	4	4	4, 3	3	3	2	2

FIGURE 11.8 Certain elements of the d-block form amphoteric oxides, particularly in oxidation states intermediate in their range (as shown here for Period 4).

character (Fig. 11.7). Substances that react with both acids and bases are classified as **amphoteric,** from the Greek word for "both." For example, aluminum oxide, Al_2O_3, is amphoteric. It reacts with acids:

$$Al_2O_3(s) + 6\ HCl(aq) \longrightarrow 2\ AlCl_3(aq) + 3\ H_2O(l)$$

and with bases:

$$2\ NaOH(aq) + Al_2O_3(s) + 3\ H_2O(l) \longrightarrow 2\ Na[Al(OH)_4](aq)$$

The product of the second reaction is sodium aluminate, which contains the aluminate ion, $Al(OH)_4^-$. Other main-group elements that form amphoteric oxides are shown in Fig.11.7. The acidic, amphoteric, or basic character of the oxides of the d-block metals depends on their oxidation state (Fig. 11.8; also see Chapter 16).

Metals form basic oxides, nonmetals form acidic oxides; the elements on a diagonal line from beryllium to polonium and several d-block metals form amphoteric oxides.

11.4 Proton Exchange Between Water Molecules

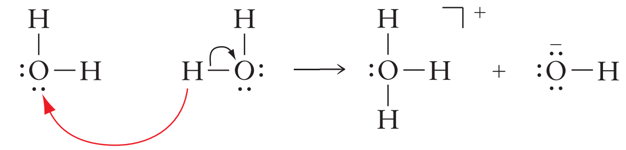
An important implication of the Brønsted definitions of acids and bases is that the same substance may be able to function as both an acid and a base. For example, we have seen that a water molecule accepts a proton from an acid molecule (such as HCl or HCN) to form an H_3O^+ ion. So water is a base. However, a water molecule can donate a proton to a base (such as O^{2-} or NH_3) and become an OH^- ion. So water is also an acid. We describe water as **amphiprotic,** meaning that an H_2O molecule can act both as a proton donor and as a proton acceptor.

A note on good practice: Distinguish between *amphoteric* and *amphiprotic*. Aluminum metal is amphoteric (it reacts with both acids and bases), but it has no hydrogen atoms to donate as protons, and is not amphiprotic.

Because water is amphiprotic—because it is both a Brønsted acid and a Brønsted base—proton transfer between water molecules occurs even in pure water, with one molecule acting as a proton donor and a neighboring molecule acting as a base:

$$2\ H_2O(l) \rightleftharpoons H_3O^+(aq) + OH^-(aq) \qquad \textbf{(A)}$$

In more detail, the forward reaction is



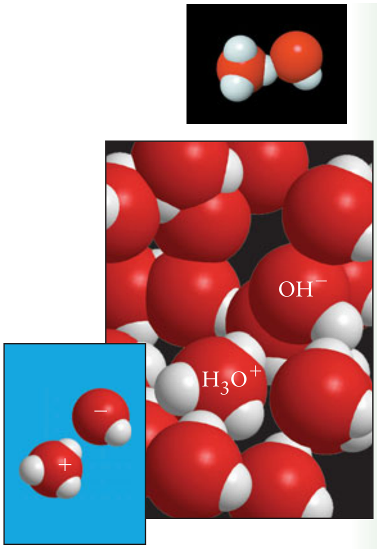


FIGURE 11.9 As a result of autoprotolysis, pure water consists of hydronium ions and hydroxide ions as well as water molecules. The concentration of ions that results from autoprotolysis is only about $10^{-7}\ mol{\cdot}L^{-1}$, and so only about 1 molecule in 200 million is ionized. The inset at the left shows only the ions.

Animation 11.9

The reaction is very fast in both directions, and so is always at equilibrium in water and in aqueous solutions. In every glass of water, protons from the hydrogen atoms are ceaselessly migrating between the molecules. This type of reaction, in which one molecule transfers a proton to another molecule of the same kind, is called **autoprotolysis** (Fig. 11.9).

The equilibrium constant for reaction A is

$$K = \frac{a_{H_3O^+}\, a_{OH^-}}{(a_{H_2O})^2}$$

K_w is also widely called the *autoionization constant* and sometimes the *ion product constant* of water.

In dilute aqueous solutions (the only ones we consider in this chapter), the solvent, water, is very nearly pure, and so its activity may be taken to be 1. The resulting expression is called the **autoprotolysis constant** of water and is written K_w:

$$K_w = a_{H_3O^+}\, a_{OH^-} \qquad \textbf{(1a)}$$

As we saw in Section 10.2, the activity of a solute J in a dilute solution is approximately equal to the molar concentration relative to the standard molar concentration, $[J]/c°$, with $c° = 1\ mol{\cdot}L^{-1}$, and so a practical form of this expression is

$$K_w = [H_3O^+][OH^-] \qquad \textbf{(1b)*}$$

where, as in Chapter 10, we have simplified the appearance of the expression by replacing $[J]/c°$ by [J], the value of the molarity in moles per liter with the units struck out.

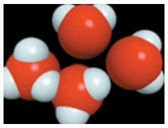
In pure water at 25°C, the molar concentrations of H_3O^+ and OH^- are equal (because the liquid is electrically neutral overall) and are known by experiment to be $1.0 \times 10^{-7}\ mol{\cdot}L^{-1}$. Therefore, at 25°C,

$$K_w = (1.0 \times 10^{-7}) \times (1.0 \times 10^{-7}) = 1.0 \times 10^{-14}$$

The concentrations of H_3O^+ and OH^- are very low in pure water, which explains why pure water is such a poor conductor of electricity. To imagine the very tiny extent of autoprotolysis, think of each letter in this book as a water molecule. We would need to search through more than 50 books to find one ionized water molecule. Unless otherwise stated, all the calculations in this chapter will be for 25°C.

Thinking point: The autoprotolysis reaction is endothermic; do you expect K_w to increase or decrease with increasing temperature?

It is important to remember that K_w is fundamentally no different from the equilibrium constants that were discussed in Chapter 10. *Because K_w is an equilibrium constant, the product of the concentrations of H_3O^+ and OH^- ions in any aqueous solution is always equal to K_w.* We can increase the concentration of H_3O^+ ions by adding acid, and the concentration of OH^- ions will immediately respond by decreasing to preserve the value of K_w. Alternatively, we can increase the concentration of OH^- ions by adding base, and the concentration of H_3O^+ ions will decrease correspondingly. The autoprotolysis equilibrium links the concentrations of H_3O^+ and OH^- ions rather like a seesaw: when one goes up, the other must go down (Fig. 11.10).



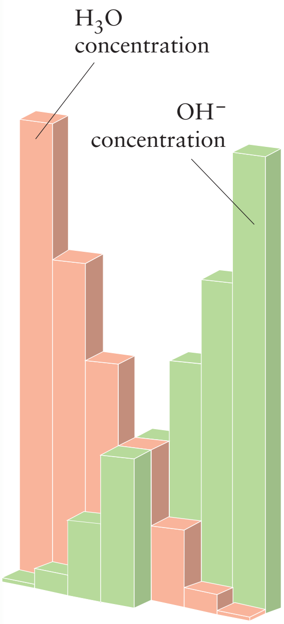


FIGURE 11.10 The product of the concentrations of hydronium and hydroxide ions in water (pure water and aqueous solutions) is a constant. If the concentration of one type of ion increases, the other must decrease to keep the product of the ion concentrations constant.

Animation 11.10

EXAMPLE 11.2 Calculating the concentrations of ions in a solution of a metal hydroxide

What are the concentrations of H_3O^+ and OH^- in 0.0030 M $Ba(OH)_2(aq)$ at 25°C?

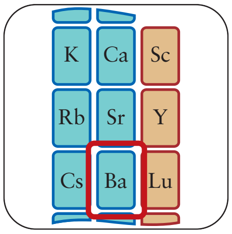
Anticipate Because the compound provides OH^- ions, they will be present in overwhelming concentration, but nevertheless there must be a tiny concentration of H_3O^+ ions to maintain the value of K_w.

PLAN Most hydroxides of Groups 1 and 2 can be treated as fully dissociated into ions in solution. Decide from the chemical formula how many OH^- ions are provided by each formula unit and calculate the concentrations of these ions in the solution. To find the concentration of H_3O^+ ions, use the water autoprotolysis constant $K_w = [H_3O^+][OH^-]$.

SOLVE

Decide whether the compound is fully dissociated in solution.

Because barium is an alkaline earth metal, $Ba(OH)_2$ dissociates almost completely in water to provide Ba^{2+} and OH^- ions.



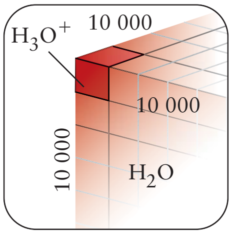
Find the mole ratio of hydroxide ion to barium hydroxide.

$$Ba(OH)_2(s) \longrightarrow Ba^{2+}(aq) + 2\ OH^-(aq) \qquad 1\ \text{mol}\ Ba(OH)_2 \simeq 2\ \text{mol}\ OH^-$$

Calculate the hydroxide ion concentration from the solute concentration.

$$[OH^-] = 2 \times 0.0030\ \text{mol·L}^{-1} = 0.0060\ \text{mol·L}^{-1}$$

Rearrange $K_w = [H_3O^+][OH^-]$ to find the concentration of H_3O^+ ions.



$$[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{0.0060} = 1.7 \times 10^{-12}$$

Evaluate The concentration of H_3O^+ ions is 1.7 pmol·L^{-1} (1 pmol = 10^{-12} mol), which is very small, as we expected; but it is not zero.

Self-Test 11.3A Estimate the concentrations of (a) H_3O^+ and (b) OH^- at 25°C in 6.0×10^{-5} M HI(aq).

[***Answer:*** (a) 60. μmol·L^{-1}; (b) 0.17 nmol·L^{-1}]

Self-Test 11.3B Estimate the concentrations of (a) H_3O^+ and (b) OH^- at 25°C in 2.2×10^{-3} M NaOH(aq).

In aqueous solutions, the concentrations of H_3O^+ and OH^- ions are related by the autoprotolysis equilibrium; if one concentration is increased, then the other must decrease to maintain the value of K_w.

11.5 The pH Scale

One difficulty with describing the concentrations of acids and bases quantitatively is that the concentration of H_3O^+ ions can vary over many orders of magnitude: in some solutions, it is higher than 1 mol·L^{-1} and, in others, it is lower than 10^{-14} mol$^-$L^{-1}. Chemists avoid the awkwardness of working with such a wide range of values by reporting the hydronium ion concentration in terms of the **pH** of the solution, the negative logarithm (to the base 10) of the hydronium ion activity:

The pH scale was introduced by the Danish chemist Søren Sørensen in 1909 in the course of his work on quality control in the brewing of beer and is now used throughout science, medicine, agriculture, and engineering.

$$pH = -\log a_{H_3O^+} \qquad \textbf{(2a)}$$

where (for solutions so dilute that they may be treated as ideal) $a_{H_3O^+} = [H_3O^+]/c°$. As in Chapter 10, we simplify the appearance of this expression by interpreting $[H_3O^+]$ as the molar concentration of H_3O^+ in moles per liter with the units struck out and write

The negative logarithm is used so that most pH values are positive numbers.

$$pH = -\log[H_3O^+] \qquad \textbf{(2b)*}$$

For example, the pH of pure water, in which the concentration of H_3O^+ ions is 1.0×10^{-7} mol·L^{-1} at 25°C, is

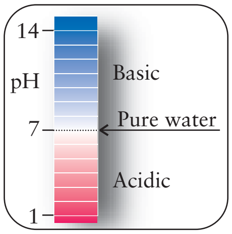
$$pH = -\log(1.0 \times 10^{-7}) = 7.00$$

Thinking point: Do you expect the pH of pure water to increase or decrease with increasing temperature?

A note on good practice: The number of digits following the decimal point in a pH value is equal to the number of significant figures in the corresponding molar concentration, because the digits preceding the decimal point simply report the power of 10 in the data (as in $\log 10^5 = 5$).

The negative sign in the definition of pH means that the higher the concentration of H_3O^+ ions, the lower the pH:

- The pH of a basic solution is greater than 7.
- The pH of pure water is 7.
- The pH of an acidic solution is less than 7.



Notice that, as the concentration of hydronium ions increases, the pH decreases. Because pH is a common logarithm (to the base 10), a change of one pH unit means that the concentration of H_3O^+ ions has changed by a factor of 10. For example, when the concentration of H_3O^+ increases by a factor of 10 from 10^{-5} mol·L^{-1} to 10^{-4} mol·L^{-1}, the pH decreases from 5 to 4. Most solutions used in chemistry have a pH ranging from 0 to 14, but values outside this range are possible.

Thinking point: Can a pH be negative? If so, what would that signify?

EXAMPLE 11.3 Calculating a pH from a concentration

What is the pH of (a) human blood, in which the concentration of H_3O^+ ions is 4.0×10^{-8} mol·L^{-1}; (b) 0.020 M HCl(aq); (c) 0.040 M KOH(aq)?

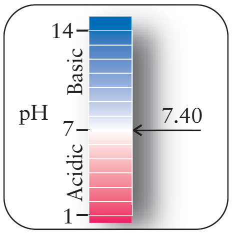
Anticipate The concentration of H_3O^+ ions in blood is lower than in pure water, so we should expect pH > 7; in HCl(aq), an acid, we should expect pH < 7, and in KOH(aq), a base, we should expect pH > 7.

PLAN The pH is calculated from Eq. 2b. For strong acids, the concentration of H_3O^+ is equal to the molarity of the acid. For strong bases, first find the concentration of OH^-, then convert that concentration into $[H_3O^+]$ by using $[H_3O^+][OH^-] = K_w$, as described in Example 11.2.

SOLVE

(a) From pH $= -\log [H_3O^+]$,

$$\text{pH} = -\log (4.0 \times 10^{-8})$$
$$= 7.40$$

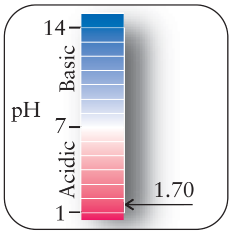


(b) HCl is a strong acid, so it is completely deprotonated in water.

$$[H_3O^+] = [HCl] = 0.020 \text{ mol·L}^{-1}$$

From pH $= -\log [H_3O^+]$,

$$\text{pH} = -\log 0.020$$
$$= 1.70$$



(c) Because KOH provides one OH^- ion per formula unit,

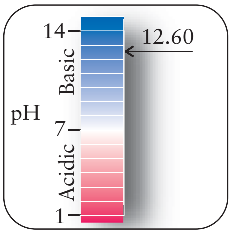
$$[OH^-] = [KOH] = 0.040 \text{ mol·L}^{-1}$$

Find $[H_3O^+]$ from $[H_3O^+][OH^-] = K_w$ in the form $[H_3O^+] = K_w/[OH^-]$.

$$[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{0.040} = 2.5 \times 10^{-13}$$

From $pH = -\log [H_3O^+]$,

$$pH = -\log (2.5 \times 10^{-13}) = 12.60$$



Evaluate The calculated pH values are in line with what we expected.

Self-Test 11.4A Calculate the pH of (a) household ammonia, in which the OH^- concentration is about 3×10^{-3} mol·L^{-1}; (b) 6.0×10^{-5} M $HClO_4$(aq).

[***Answer:*** (a) 11.5; (b) 4.22]

Self-Test 11.4B Calculate the pH of 0.077 M NaOH(aq).

The approximate value of the pH of an aqueous solution can be determined very quickly by using a strip of *universal indicator paper*, which turns different colors at different pH values. More precise measurements are made with a *pH meter* (Fig. 11.11). This instrument consists of a voltmeter connected to two electrodes that dip into the solution. The difference in electrical potential between the electrodes is proportional to the hydronium ion activity (as will be explained in Section 13.10); so, once the scale on the meter has been calibrated, the pH can be read directly.

To convert a pH into a concentration of H_3O^+ ions, we reverse the sign of the pH and then take its antilogarithm:

$$[H_3O^+] = 10^{-pH} \text{ mol·L}^{-1} \tag{3}$$

EXAMPLE 11.4 Calculating the hydronium ion concentration from the pH

What is the hydronium ion concentration in a solution with pH = 4.83?

Anticipate Because the pH is less than 7, the pH of pure water, the solution must be acidic and we should expect a concentration of H_3O^+ ions greater than 10^{-7} mol·L^{-1}.

PLAN To calculate the precise value from Eq. 3, we first change the sign of the pH and then take its antilogarithm.

(a) (b)

FIGURE 11.11 A pH meter is a voltmeter that measures the pH electrochemically. The two samples are (a) orange juice and (b) lemon juice. Notice that the lemon juice has a lower pH and hence a higher concentration of hydronium ions.

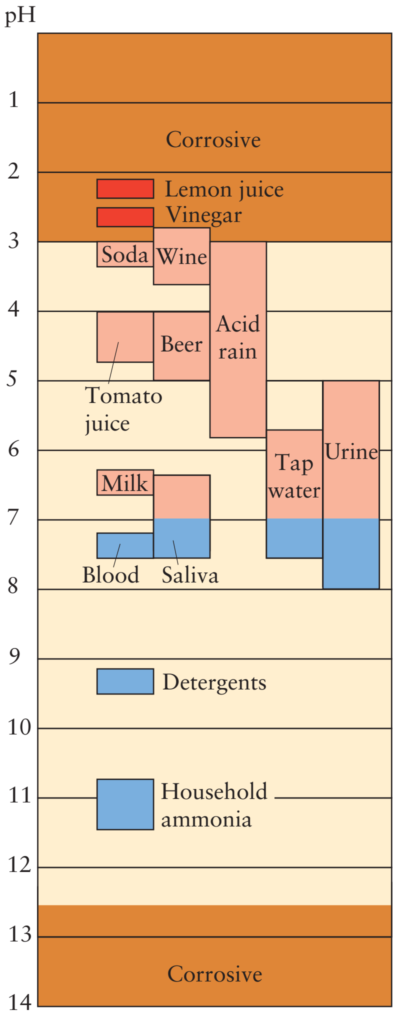


FIGURE 11.12 Typical pH values of some common aqueous solutions. The rust-colored regions indicate the pH ranges for liquids regarded as corrosive.

SOLVE

From $[H_3O^+] = 10^{-pH}$ mol·L^{-1},

$$[H_3O^+] = 10^{-4.83}\ \text{mol·L}^{-1} = 1.5 \times 10^{-5}\ \text{mol·L}^{-1}$$

Evaluate As expected, the concentration is higher than in pure water, by a factor of more than 100.

Self-Test 11.5A The pH of stomach fluids is about 1.7. What is the concentration of H_3O^+ ions in the stomach?

[***Answer:*** 2×10^{-2} mol·L^{-1}]

Self-Test 11.5B The pH of pancreatic fluids, which help to digest food once it has left the stomach, is about 8.2. What is the approximate concentration of H_3O^+ ions in pancreatic fluids?

Figure 11.12 shows the results of measuring the pH of a selection of liquids and beverages. Fresh lemon juice, as we have seen, has a pH of 2.5, corresponding to an H_3O^+ concentration of 3 mmol·L^{-1} (with 1 mmol = 10^{-3} mol). Natural (unpolluted) rain, with an acidity due largely to dissolved carbon dioxide, typically has a pH of about 5.7. In the United States, the Environmental Protection Agency (EPA) defines waste as "corrosive" if its pH is either lower than 3.0 (highly acidic) or higher than 12.5 (highly basic). Lemon juice, with a pH of about 2.5, would be regarded as corrosive; so would solutions of 1 M NaOH(aq), for which the pH is 14.

The pH scale is used to report H_3O^+ concentration: pH = −log $[H_3O^+]$; pH > 7 denotes a basic solution, pH < 7 an acidic solution; a neutral solution has pH = 7.

11.6 The pOH of Solutions

Many quantitative expressions relating to acids and bases are greatly simplified and therefore much easier to remember when we use logarithms. The quantity pX is a generalization of pH:

$$\text{pX} = -\log \text{X} \qquad (4)$$

For example, **pOH** is defined as

$$\text{pOH} = -\log a_{OH^-} \qquad (5a)$$

which, for the same reasons as those for pH, is normally simplified to

$$\text{pOH} = -\log[OH^-] \qquad (5b)^*$$

The pOH is convenient for reporting the concentration of OH^- ions in solution. For example, in pure water, where $[OH^-] = 1.0 \times 10^{-7}$ mol·L^{-1}, the pOH is 7.00. Similarly, by pK_w we mean

$$pK_w = -\log K_w = -\log(1.0 \times 10^{-14}) = 14.00 \text{ (at 25°C)}$$

The values of pH and pOH for a given solution are related. To find that relation, we start with the expression for the autoprotolysis constant of water written as $[H_3O^+][OH^-] = K_w$. Then we take logarithms of both sides:

$$\log [H_3O^+][OH^-] = \log K_w$$

Now we use $\log ab = \log a + \log b$ to obtain:

$$\log [H_3O^+] + \log [OH^-] = \log K_w$$

Multiplication of both sides of the equation by −1 gives

$$-\log [H_3O^+] - \log [OH^-] = -\log K_w$$

which is the same as

$$\mathrm{pH} + \mathrm{pOH} = \mathrm{p}K_{\mathrm{w}} \qquad \textbf{(6a)*}$$

Because $\mathrm{p}K_{\mathrm{w}} = 14.00$ at 25°C, at this temperature

$$\mathrm{pH} + \mathrm{pOH} = 14.00 \qquad \textbf{(6b)}$$

Equation 6 shows that the pH and pOH of a solution have complementary values: if one increases, the other decreases such that their sum remains constant (Fig. 11.13).

The pH and pOH of a solution are related by the expression pH + pOH = pK_w.

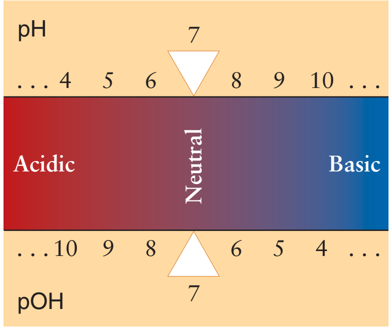

FIGURE 11.13 The numbers along the top of the rectangle are values of pH for a range of solutions. Directly below each pH value is the pOH value of the same solution. Notice that the sum of the pH and pOH values for a given solution is always 14. Most values of pH and pOH lie in the range from 1 to 14, but pH and pOH values can lie outside this range and even be negative.

WEAK ACIDS AND BASES

Solutions of different acids having the same concentration might not have the same pH. For instance, the pH of 0.10 M $CH_3COOH(aq)$ is close to 3; but that of 0.10 M HCl(aq) is close to 1. We have to conclude that the concentration of H_3O^+ ions in 0.10 M $CH_3COOH(aq)$ is *lower* than that in 0.10 M HCl(aq). Similarly, we find that the concentration of OH^- ions is lower in 0.10 M $NH_3(aq)$ than it is in 0.10 M NaOH(aq). The explanation must be that in water CH_3COOH is not fully deprotonated and NH_3 is not fully protonated. That is, acetic acid and ammonia are, respectively, a weak acid and a weak base. The incomplete deprotonation of CH_3COOH explains why solutions of HCl and CH_3COOH with the same molarity react with a metal at different rates (Fig. 11.14).

Most acids and bases that exist in nature are weak. For example, the natural acidity of river water is generally due to the presence of carbonic acid (H_2CO_3, from dissolved CO_2), hydrogen phosphate ions, HPO_4^{2-}, dihydrogen phosphate ions, $H_2PO_4^-$ (from fertilizer runoff), and carboxylic acids arising from the degradation of plant tissues. Similarly, most naturally occurring bases are weak. Some arise from the decomposition (in the absence of air) of compounds containing nitrogen. For example, the odor of dead fish is due to amines, which are weak bases.

Lemon juice, which contains citric acid, is often added to fish dishes to help eliminate the smell of some of these amines.

In this part of the chapter, we develop a quantitative measure of the strengths of weak acids and bases. We then use this information to explore how acid strength is related to molecular structure.

11.7 Acidity and Basicity Constants

When we visualize the molecular composition of a solution of a weak acid in water, we think of a solution that contains

- the acid molecules or ions;
- small concentrations of H_3O^+ ions and the conjugate base of the acid; and

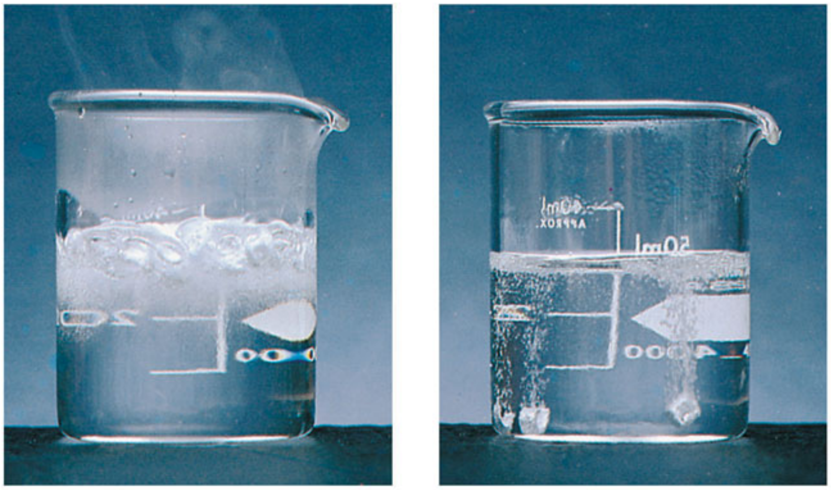

FIGURE 11.14 The same mass of magnesium metal has been added to solutions of HCl, a strong acid (left), and CH_3COOH, a weak acid (right). Although the acid solutions were prepared with the same concentrations, the rate of hydrogen evolution, which depends on the concentration of hydronium ions, is much greater in the strong acid.

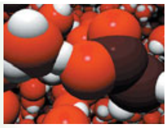

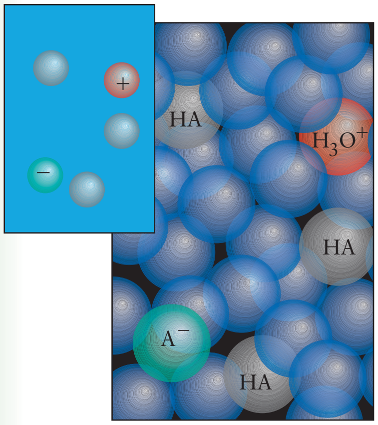

FIGURE 11.15 In a solution of a weak acid, only some of the acidic hydrogen atoms are present as hydronium ions (the red sphere), and the solution contains a high proportion of the original acid molecules (HA, gray spheres). The green sphere represents the conjugate base of the acid and the blue spheres are water molecules. The inset at the left shows only the solute species.

Animation 11.15

K_a is also widely called the acid ionization constant or acid dissociation constant.

- a very, very small concentration of OH^- ions that maintain the autoprotolysis equilibrium.

All these species are in ceaseless dynamic equilibrium. Similarly, for a solution of a weak base, we visualize

- the base molecules or ions;
- small concentrations of OH^- ions and the conjugate acid of the base; and
- a very, very small concentration of H_3O^+ ions that maintain the autoprotolysis equilibrium.

Because conjugate acids and bases are in equilibrium in solution, we can use the equilibrium constant for proton transfer between the solute and the solvent as an indicator of their strengths. For example, for acetic acid in water,

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq) \qquad \textbf{(B)}$$

the equilibrium constant is

$$K = \frac{a_{H_3O^+}\, a_{CH_3CO_2^-}}{a_{CH_3COOH}\, a_{H_2O}} \qquad (7)$$

Because the solutions that we are considering are dilute and the water is almost pure, the activity of H_2O can be set equal to 1. The resulting expression is called the **acidity constant,** K_a, of acetic acid. If we make the further approximation of replacing the activities of the solute species by the numerical values of their molar concentrations, we can write the acidity constant expression for acetic acid as

$$K_a = \frac{[H_3O^+][CH_3CO_2^-]}{[CH_3COOH]}$$

The experimental value of K_a for acetic acid at 25°C is 1.8×10^{-5}. This small value tells us that only a small proportion of CH_3COOH molecules donate their protons when dissolved in water. About 99 of 100 CH_3COOH molecules remain intact in 1 M $CH_3COOH(aq)$ (the actual value depends on the concentration of acid, as we shall see). This value is typical of weak acids in water (Fig. 11.15). In general, the acidity constant of an acid HA is

$$HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq) \qquad K_a = \frac{[H_3O^+][A^-]}{[HA]} \qquad \textbf{(8)*}$$

Table 11.1 lists the acidity constants of some other weak acids in aqueous solution.

We can also write an equilibrium constant for the proton transfer equilibrium of a base in water. For aqueous ammonia, for instance,

$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq) \qquad \textbf{(C)}$$

TABLE 11.1 Acidity Constants at 25°C*

Acid	K_a	pK_a	Acid	K_a	pK_a
trichloroacetic acid, CCl_3COOH	3.0×10^{-1}	0.52	formic acid, HCOOH	1.8×10^{-4}	3.75
benzene sulfonic acid, $C_6H_5SO_3H$	2.0×10^{-1}	0.70	benzoic acid, C_6H_5COOH	6.5×10^{-5}	4.19
iodic acid, HIO_3	1.7×10^{-1}	0.77	acetic acid, CH_3COOH	1.8×10^{-5}	4.75
sulfurous acid, H_2SO_3	1.5×10^{-2}	1.81	carbonic acid, H_2CO_3	4.3×10^{-7}	6.37
chlorous acid, $HClO_2$	1.0×10^{-2}	2.00	hypochlorous acid, HClO	3.0×10^{-8}	7.53

chloroacetic acid, $CH_2ClCOOH$	1.4×10^{-3}	2.85	boric acid, $B(OH)_3$†	7.2×10^{-10}	9.14
lactic acid, $CH_3CH(OH)COOH$	8.4×10^{-4}	3.08	hydrocyanic acid, HCN	4.9×10^{-10}	9.31
nitrous acid, HNO_2	4.3×10^{-4}	3.37	phenol, C_6H_5OH	1.3×10^{-10}	9.89
hydrofluoric acid, HF	3.5×10^{-4}	3.45	hypoiodous acid, HIO	2.3×10^{-11}	10.64

*The values for K_a listed here have been calculated from pK_a values with more significant figures than shown so as to minimize rounding errors. Values for polyprotic acids—those capable of donating more than one proton—refer to the first deprotonation.

†The proton transfer equilibrium is $B(OH)_3 + 2\,H_2O(l) \rightleftharpoons H_3O^+(aq) + B(OH)_4^-(aq)$.

the equilibrium constant is

$$K = \frac{a_{NH_4^+}a_{OH^-}}{a_{H_2O}a_{NH_3}}$$

In dilute solutions, the water is almost pure and its activity can be set equal to 1. With this approximation, we obtain the **basicity constant,** K_b. If we make the further approximation of replacing the activities of the solute species by the numerical values of their molar concentrations, we can write the basicity constant expression for ammonia as

K_b is also widely called the base ionization constant.

$$K_b = \frac{[NH_4^+][OH^-]}{[NH_3]}$$

The experimental value of K_b for ammonia in water at 25°C is 1.8×10^{-5}. This small value tells us that normally only a small proportion of the NH_3 molecules are present as NH_4^+. Equilibrium calculations show that only about 1 in 100 molecules are protonated in a typical solution (Fig. 11.16). In general, the basicity constant for a base B in water is

$$B(aq) + H_2O(l) \rightleftharpoons HB^+(aq) + OH^-(aq) \qquad K_b = \frac{[HB^+][OH^-]}{[B]} \qquad \textbf{(9)*}$$

The value of K_b tells us how far the reaction proceeds to the right. The smaller the value of K_b the weaker is the ability of the base to accept a proton. Table 11.2 lists the basicity constants of some weak bases in aqueous solution.

Acidity and basicity constants are commonly reported as their negative logarithms, by defining

$$pK_a = -\log K_a \qquad pK_b = -\log K_b \qquad \textbf{(10)*}$$

When thinking about the strengths of acids and bases we should note that:

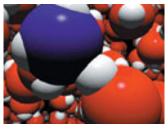
- The weaker the acid, the smaller the value of K_a and the greater the value of pK_a.

For example, the pK_a of trichloroacetic acid is 0.5, whereas that of acetic acid, a much weaker acid, is nearly 5. Similar remarks apply to bases:

- The weaker the base, the smaller the value of K_b and the greater the value of pK_b.

Values of pK_a and pK_b are included in Tables 11.1 and 11.2.

The proton-donating strength of an acid is measured by its acidity constant; the proton-accepting strength of a base is measured by its basicity constant. The smaller the constants, the weaker the respective strengths. The larger the value of pK, the weaker the acid or base.



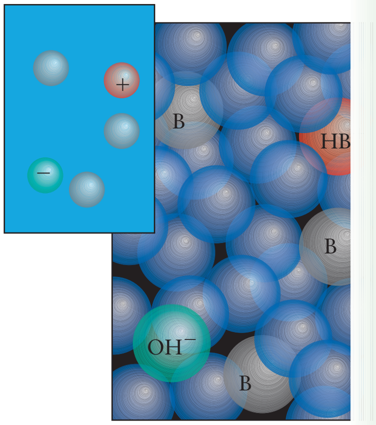


FIGURE 11.16 In a solution of a weak base, only a small proportion of the base molecules (B, represented here by gray spheres) have accepted protons from water molecules (the blue spheres) to form HB^+ ions (the red sphere) and OH^- ions (green sphere). The inset at the left shows only the solute species.

Animation 11.16

TABLE 11.2 Basicity Constants at 25°C*

Base	K_b	pK_b	Base	K_b	pK_b
urea, $CO(NH_2)_2$	1.3×10^{-14}	13.90	ammonia, NH_3	1.8×10^{-5}	4.75

*The values for K_b listed here have been calculated from pK_b values with more significant figures than shown so as to minimize rounding errors.

11.8 The Conjugate Seesaw

Hydrochloric acid is classified as a strong acid because it is fully deprotonated in water. It follows that its conjugate base, Cl^-, must be a very, very weak proton acceptor (weaker, in fact, than H_2O). Conversely, acetic acid is a weak acid. Its conjugate base, the acetate ion, $CH_3CO_2^-$, must be a relatively good proton acceptor, because it readily forms CH_3COOH molecules in water. Similarly, because methylamine, CH_3NH_2, is a stronger base than ammonia (see Table 11.2), the conjugate acid of methylamine—the methylammonium ion, $CH_3NH_3^+$—must be a weaker proton donor (and therefore a weaker acid) than NH_4^+. In general,

- the stronger the acid, the weaker its conjugate base; and
- the stronger the base, the weaker its conjugate acid.

To express the relative strengths of an acid and its conjugate base (a "conjugate acid–base pair"), we consider the special case of the ammonia proton transfer equilibrium, reaction C, for which the basicity constant was given earlier ($K_b = [NH_4^+][OH^-]/[NH_3]$). The proton transfer equilibrium of ammonia's conjugate acid, NH_4^+, in water is

$$NH_4^+(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + NH_3(aq) \qquad K_a = \frac{[H_3O^+][NH_3]}{[NH_4^+]}$$

Multiplication of the two equilibrium constants, K_a for NH_4^+ and K_b for NH_3, gives

$$K_a \times K_b = \frac{[H_3O^+][NH_3]}{[NH_4^+]} \times \frac{[NH_4^+][OH^-]}{[NH_3]} = [H_3O^+][OH^-]$$

We recognize K_w on the right; so we can write

$$K_a \times K_b = K_w \qquad \textbf{(11a)*}$$

We can express Eq. 11a in another way by taking logarithms of both sides of the equation:

$$\log K_a + \log K_b = \log K_w$$

Multiplication throughout by –1 turns this expression into

$$pK_a + pK_b = pK_w \qquad \textbf{(11b)*}$$

These expressions apply to any conjugate acid–base pair, with K_a the acidity constant of the acid and K_b the basicity constant of its conjugate base.

Self-Test 11.6A Write the chemical formula for the conjugate acid of the base pyridine, C_5H_5N, and calculate its pK_a.

[*Answer:* $C_5H_5NH^+$, 5.25]

Self-Test 11.6B Write the chemical formula for the conjugate base of the acid HIO_3 and calculate its pK_b.

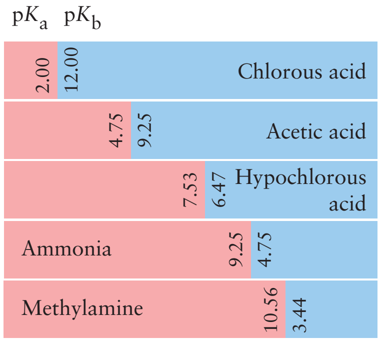

FIGURE 11.17 As shown here for five conjugate acid–base pairs, the sum of the pK_a of an acid (pink) and the pK_b of its conjugate base (blue) is constant and equal to pK_w, which is 14.00 at 25°C.

Equation 11—in either form—confirms the seesaw relation between the strengths of acids and of their conjugate bases. Equation 11a tells us that if an acid has a large K_a, then its conjugate base must have a small K_b. Similarly, if a base has a large K_b, then its conjugate acid must have a small K_a. Equation 11b tells us that if pK_a of an acid is large, then the pK_b of its conjugate base is small, and vice versa. This reciprocal relation is summarized in Fig. 11.17 and Table 11.3. For example, because pK_b for ammonia in water is 4.75, the pK_a of NH_4^+ is

$$pK_a = pK_w - pK_b = 14.00 - 4.75 = 9.25$$

This value shows that NH_4^+ is a weaker acid than boric acid ($pK_a = 9.14$) but stronger than hydrocyanic acid (HCN, $pK_a = 9.31$). Consequently, as we shall verify in Section 11.13, solutions of ammonium salts such as NH_4Cl are acidic.

TABLE 11.3 Conjugate Acid–Base Pairs Arranged by Strength

pK_a	Acid name	Acid formula	Base formula	Base name	pK_b
	Strong acid			*Very weak base*	
	hydroiodic acid	HI	I^-	iodide ion	
	perchloric acid	$HClO_4$	ClO_4^-	perchlorate ion	
	hydrobromic acid	HBr	Br^-	bromide ion	
	hydrochloric acid	HCl	Cl^-	chloride ion	
	sulfuric acid	H_2SO_4	HSO_4^-	hydrogen sulfate ion	
	chloric acid	$HClO_3$	ClO_3^-	chlorate ion	
	nitric acid	HNO_3	NO_3^-	nitrate ion	
	hydronium ion	H_3O^+	H_2O	*water*	
1.92	hydrogen sulfate ion	HSO_4^-	SO_4^{2-}	sulfate ion	12.08
3.37	nitrous acid	HNO_2	NO_2^-	nitrite ion	10.63
3.45	hydrofluoric acid	HF	F^-	fluoride ion	10.55
4.75	acetic acid	CH_3COOH	$CH_3CO_2^-$	acetate ion	9.25
6.37	carbonic acid	H_2CO_3	HCO_3^-	hydrogen carbonate ion	7.63
6.89	hydrosulfuric acid	H_2S	HS^-	hydrogen sulfide ion	7.11
9.25	ammonium ion	NH_4^+	NH_3	ammonia	4.75
9.31	hydrocyanic acid	HCN	CN^-	cyanide ion	4.69
10.25	hydrogen carbonate ion	HCO_3^-	CO_3^{2-}	carbonate ion	3.75
	methylammonium ion	$CH_3NH_3^+$	CH_3NH_2	methylamine	3.44
	water	H_2O	OH^-	*hydroxide ion*	
	ammonia	NH_3	NH_2^-	amide ion	
	hydrogen	H_2	H^-	hydride ion	
	methane	CH_4	CH_3^-	methide ion	
	hydroxide ion	OH^-	O^{2-}	oxide ion	
	Very weak acid			*Strong base*	

Although the proton transfer in a solution of a strong acid is actually an equilibrium, the proton-donating power of a strong acid, HA, is so much greater than that of H_3O^+ that proton transfer to water effectively goes to completion. As a result, the solution contains only H_3O^+ ions and A^- ions; there are virtually no HA molecules left. In other words, the only acid species present in an aqueous solution of a strong acid, other than the H_2O molecules, is the H_3O^+ ion. Because all strong acids in water behave as though they were solutions of the acid H_3O^+, we say that strong acids are **leveled** in water to the strength of the acid H_3O^+.

Sulfuric acid is a special case, because loss of its first acidic hydrogen leaves a conjugate base that is itself a weak acid, the HSO_4^- ion.

EXAMPLE 11.5 Deciding which of two species is the stronger acid or base

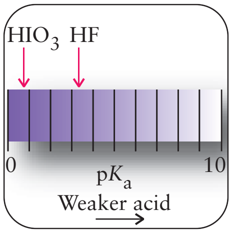
Decide which member of each of the following pairs is the stronger acid or base in water: (a) acid: HF or HIO_3; (b) base: NO_2^- or CN^-.

PLAN The greater the K_a of a weak acid, the stronger is the acid and the weaker is its conjugate base. Similarly, the greater the K_b of a weak base, the stronger is the base and the weaker is its conjugate acid.

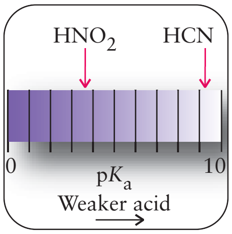
SOLVE

Compare the relevant K_a and K_b (or pK_a and pK_b) values in Tables 11.1 and 11.2.

(a) Because $K_a(HIO_3) > K_a(HF)$, or $pK_a(HIO_3) < pK_a(HF)$, HIO_3 is a stronger acid than HF.



(b) Because $K_a(HNO_2) > K_a(HCN)$, or $pK_a(HNO_2) < pK_a(HCN)$, HNO_2 is a stronger acid than HCN. Because the stronger acid has the weaker conjugate base, NO_2^- is a weaker base than CN^-. Hence, CN^- is the stronger base.



Self-Test 11.7A Use Tables 11.1 and 11.2 to decide which species in each of the following pairs is the stronger acid or base: (a) acid: HF or HIO; (b) base: $C_6H_5CO_2^-$ or $CH_2ClCO_2^-$; (c) base: $C_6H_5NH_2$ or $(CH_3)_3N$; (d) acid: $C_6H_5NH_3^+$ or $(CH_3)_3NH^+$.

[***Answer:*** Stronger acids: (a) HF; (d) $C_6H_5NH_3^+$. Stronger bases: (b) $C_6H_5CO_2^-$; (c) $(CH_3)_3N$.]

Self-Test 11.7B Use Tables 11.1 and 11.2 to decide which species in each of the following pairs is the stronger acid or base: (a) base: C_5H_5N or NH_2NH_2; (b) acid: $C_5H_5NH^+$ or $NH_2NH_3^+$; (c) acid: HIO_3 or $HClO_2$; (d) base: ClO_2^- or HSO_3^-.

The stronger the acid, the weaker its conjugate base; the stronger the base, the weaker its conjugate acid.

11.9 Molecular Structure and Acid Strength

Chemists commonly interpret trends in the properties of compounds by considering the structures of their molecules. However, there are two reasons why the relative strengths of acids and bases are difficult to predict. First, K_a and K_b are equilibrium constants, and so they are related to the Gibbs free energy of the proton transfer reaction. Their values therefore depend on considerations of entropy as well as energy. Second, the solvent plays a significant role in the proton transfer reactions, and so we cannot expect to relate acid strength solely to the acid molecule itself. However, although absolute values are difficult to predict, we can look for trends among series of compounds with similar structures and in the same solvent (normally water). Because acid strength in aqueous solutions depends on the breaking of the H—A bond and the formation of an $H—OH_2^+$ bond, we might suspect that one factor in determining strength is the ease with which these bonds can be broken and formed.

Here is an opportunity for you to come up with a theory.

Thinking point: Do you think that the entropy of the system will increase or decrease when an acid molecule is deprotonated in water?

First, we consider *binary acids*, acids composed of hydrogen and one other element, such as HCl and H_2S and, in general, HA. Because the enthalpy change for a process does not depend on the path, we can break down the enthalpy change for the transfer of a proton from HA to H_2O in solution into the following hypothetical sequence (Fig. 11.18):

Step	Reaction	Enthalpy change
removal of HA from solution:	$HA(aq) \longrightarrow HA(g)$	$-\Delta H_{solv}(HA)$
dissociation of HA:	$HA(g) \longrightarrow H(g) + A(g)$	$\Delta H_B(H—A)$
ionization of H:	$H(g) \longrightarrow H^+(g) + e^-(g)$	$I(H)$
electron attachment to A:	$A(g) + e^-(g) \longrightarrow A^-(g)$	$-E_a(A)$
hydration of H^+:	$H^+(g) + H_2O(l) \longrightarrow H_3O^+(aq)$	$\Delta H_{hyd}(H^+)$
hydration of A^-:	$A^-(g) \longrightarrow A^-(aq)$	$\Delta H_{hyd}(A^-)$

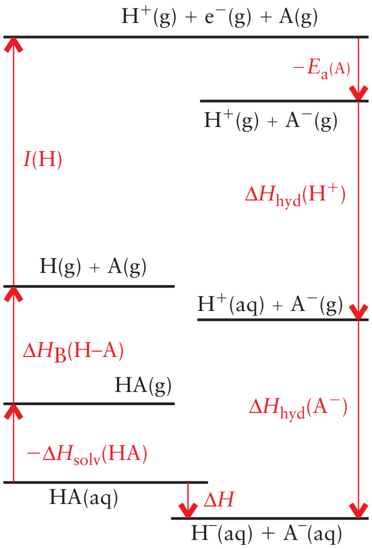


FIGURE 11.18 The thermodynamic cycle for the analysis of contributions to the strengths of binary acids.

The enthalpy change for the overall process $HA(aq) + H_2O(l) \longrightarrow H_3O^+(aq) + A^-(aq)$ is therefore

$$\Delta H = -\Delta H_{solv}(HA) + \Delta H_B(H—A) + I(H) - E_a(A) + \Delta H_{hyd}(H^+) + \Delta H_{hyd}(A^-)$$

TABLE 11.4 Contributions to the Enthalpy of Proton Transfer of Binary Acids (all values in kJ·mol^{-1})*

Acid	ΔH_{solv}(HA)	ΔH_B(H—A)	I(H)	E_a(A)	$\Delta H_{hyd}(H^+)$	$\Delta H_{hyd}(A^-)$	ΔH
HF	−49	565	1312	328	−1103	−510	−15
HCl	?−35	431	1312	349	−1103	−367	−41
HBr	?−35	366	1312	325	−1103	−336	−51
HI	?−35	299	1312	295	−1103	−291	−43
H_2O	−41	492	1312	178	−1103	−520	+44
NH_3	−34	453	1312	71	−1103	−500	+125

*We have grayed out contributions that are constant for all the acids. The colors are explained in the text. The values preceded with ? are estimates. The electron affinities are for the negative ions.

Table 11.4 lists the values for a number of binary acids, including H_2O (the value for its removal from solution, $-\Delta H_{solv}$, corresponds to its vaporization), and the resulting value of ΔH for proton transfer to water molecules. Notice that here NH_3 is included in its role as an acid that can lose H^+ to form NH_2^-. Our task is to try to identify the contributions that account for the trends in acid strength. We have to bear in mind, as remarked above, that we should really be considering Gibbs free energies, but the role of entropy is hard to estimate. Any discrepancies between what we identify and what we observe might be due to the neglect of entropy considerations. We therefore take the cautious view that as the enthalpy of proton transfer (the value of ΔH in the table) becomes more negative (proton transfer becoming more exothermic), the acid strength of HA increases.

First, consider trends across a period (the top row and bottom two rows of Table 11.4, which refer to N, O, and F in Period 2). We know that acid strength increases in the order $NH_3 < H_2O <$ HF, and we see that ΔH follows this trend:

	NH_3	H_2O	HF
ΔH (kJ·mol^{-1})	+125	+44	−15

The dominant contribution to the relative strengths of acids across a period appears to be the trend in electron affinities across the period (see the blue numbers in the table). One way to interpret the role of electron affinity is to note its role in the definition of electronegativity (Section 2.12) and bond polarity. First, we note that the stronger the hydrogen bond that HA forms with the O atom of an H_2O molecule, the more likely it is that the proton will be transferred. We know that the more polar the H—A bond, the greater the partial positive charge on the H atom—therefore the stronger the $H_2O\cdots$H—A hydrogen bond and the more readily HA loses its proton. Because the polarity of the H—A bond increases with the electron affinity and the electronegativity of A, we can understand that *the greater the electronegativity of A, the stronger the acid HA*. For instance, the electronegativity difference is 0.8 for the N—H bond and 1.8 for F—H (see Fig. 2.12); therefore, the F—H bond is markedly more polar than the N—H bond. This difference is consistent with the observation that HF, but not NH_3, is an acid in water.

Now consider the relative strengths of the binary acids within the same group. We know that in Group VII/17 the acid strengths are in the order HF < HCl < HBr < HI. The values of ΔH almost follow this trend:

	HF	HCl	HBr	HI
ΔH (kJ·mol^{-1})	−15	−41	−51	−43

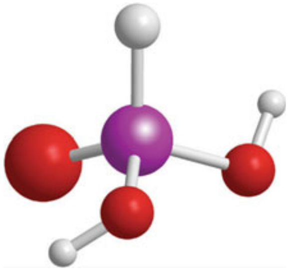
The enthalpy for proton transfer from HI to water is not consistent with the experimentally measured trend: that might be an entropy effect. The dominant contribution to the relative strengths of acids down a group appears to be the trend in bond enthalpies (see the red numbers in the table). The enthalpies of hydration of A^- admittedly change a lot, but they change in a way that is opposite to the observed trend in

strengths (hydration gets less exothermic on descending the group), so the trend in bond enthalpies must dominate even that trend.

> ***Acid strengths of binary acids across a period correlate with electron affinities; acid strengths down a group correlate with bond strength.***

11.10 The Strengths of Oxoacids and Carboxylic Acids

We can learn more about the effect of structure on acidity by considering the oxoacids. These acids form structurally related families, and so we can examine the effect of different central atoms with the same number of O atoms (as in $HClO_3$ and $HBrO_3$). Alternatively, we can look at the influence of different numbers of O atoms attached to the same central atom (as in $HClO_3$ and $HClO_4$). For the binary acids we examined contributions to the enthalpies of proton transfer, but there is little data available on electron affinities of polyatomic species, so instead we shall build on the correlations with bond polarity established in Section 11.9.



1 Phophorous acid, H_3PO_3

The high polarity of the O—H bond is one reason why the proton of an —OH group in an oxoacid molecule is acidic. For example, phosphorous acid, H_3PO_3, has the structure $(HO)_2PHO$ (**1**): it can donate the protons from its two —OH groups but not the proton attached directly to the phosphorus atom. The difference in behavior can be traced to the much lower electronegativity of phosphorus (2.2) relative to that of oxygen (3.4). In nearly all common inorganic oxoacids, however, all the hydrogen atoms are attached to oxygen atoms.

Let's consider a family of oxoacids in which the number of O atoms is constant, as in the hypohalous acids HClO, HBrO, and HIO. By referring to Table 11.5, we see that, *the greater the electronegativity of the halogen, the stronger the oxoacid*. A partial explanation of this trend is that electrons are withdrawn slightly from the O—H bond as the electronegativity of the halogen increases. As these bonding electrons move toward the central atom, the O—H bond becomes more polar, and so the molecule becomes a stronger acid. A halogen that has a high electronegativity also weakens the conjugate base by making the electrons in the molecule less accessible to an incoming proton.

Now let's consider a family of oxoacids in which the number of oxygen atoms varies, as in the chlorine oxoacids HClO, $HClO_2$, $HClO_3$, and $HClO_4$ or in the sulfur oxoacids H_2SO_3 and H_2SO_4. When we refer to Table 11.6, we see that *the greater the number of oxygen atoms attached to the central atom, the stronger the acid*. Because

TABLE 11.5 Correlation of Acid Strength and Electronegativity

Acid, HXO	Structure*	Electronegativity of atom X	pK_a	
hypochlorous acid, HClO	:Cl—O—H	3.2	7.53	hypobromous acid, HBrO	:Br—O—H	3.0	8.69	hypoiodous acid, HIO	:I—O—H	2.7	10.64	
*The red arrows indicate the direction of the shift of electron density away from the O—H bond.

TABLE 11.6 Correlation of Acid Strength and Oxidation Number

Acid	Structure*	Oxidation number of Cl atom	pK_a	
hypochlorous acid, HClO		+1	7.53	chlorous acid, $HClO_2$		+3	2.00	chloric acid, $HClO_3$		+5	strong	perchloric acid, $HClO_4$		+7	strong	
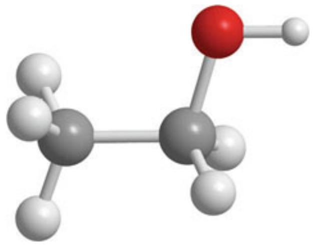
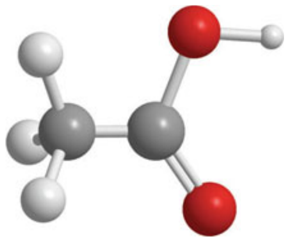
*The red arrows indicate the direction of the shift of electron density away from the O—H bond. The Lewis structures shown are the ones with the most favorable formal charges, but it is unlikely that the bond orders are as high as these structures suggest.

the oxidation number of the central atom increases as the number of O atoms increases, we can also conclude that, *the greater the oxidation number of the central atom, the stronger the acid*.

The effect of the number of O atoms on the strengths of organic acids is similar. For example, we have seen (Section D) that alcohols are organic compounds in which an —OH group is attached to a carbon atom, as in ethanol (**2**). Carboxylic acids, on the other hand, have two O atoms attached to the same carbon atom: one is a doubly bonded terminal O atom and the other is the O atom of an —OH group, as in acetic acid (**3**). Although carboxylic acids are weak acids, they are much stronger acids than alcohols, partly as a result of the electron–withdrawing power of the second O atom. In fact, alcohols have such weak proton–donating power that usually they are not regarded as oxoacids.

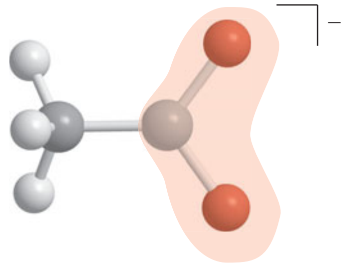


2 Ethanol, CH_3CH_2OH



3 Acetic acid, CH_3COOH

The strength of a carboxylic acid is also increased relative to that of an alcohol by electron delocalization in the conjugate base. The second O atom of the carboxyl group, —COOH, provides an additional electronegative atom over which the negative charge of the conjugate base can spread. This electron delocalization stabilizes the carboxylate anion, $—CO_2^-$ (**4**). Moreover, because the charge is spread over several atoms, it is less effective at attracting a proton. A carboxylate ion is therefore a much weaker base than the conjugate base of an alcohol (for example, the ethoxide ion, $CH_3CH_2O^-$).



4 Acetate ion, $CH_3CO_2^-$

A note on good practice: The formula of a carboxylic acid is written RCOOH, because the two O atoms are distinct (one is part of an OH group); the formula of a carboxylate ion, however, is written RCO_2^- because the two O atoms are equivalent.

The strengths of carboxylic acids also vary with the total electron withdrawing power of the atoms bonded to the carboxyl group. Because hydrogen is less electronegative than chlorine (2.2 and 3.2, respectively), the —CH_3 group bonded to —COOH in acetic acid is less electron withdrawing than the —CCl_3 group in trichloroacetic acid. Therefore, we expect CCl_3COOH to be a stronger acid than CH_3COOH. In agreement with this prediction, the pK_a of acetic acid is 4.75, whereas that of trichloroacetic acid is 0.52.

EXAMPLE 11.6 Predicting relative acid strength from molecular structure

Predict from their molecular structures which acid in each of the following pairs is the stronger: (a) H_2S and H_2Se; (b) H_2SO_4 and H_2SO_3; (c) H_2SO_4 and H_3PO_4.

PLAN Identify the relevant trends in the summary in Table 11.7.

SOLVE

(a) Sulfur and selenium are in the same group, and we expect the H—Se bond to be weaker than the H—S bond.

Thus, H_2Se can be expected to be the stronger acid.

(b) H_2SO_4 has the greater number of O atoms bonded to the S atom and the oxidation number of sulfur is +6, whereas in H_2SO_3 the sulfur has an oxidation number of only +4.

TABLE 11.7 Correlations of Molecular Structure and Acid Strength*

Acid type	Trend	
binary	The more polar the H—A bond, the stronger the acid. *This effect is dominant for acids of the same period.*		The weaker the H—A bond, the stronger the acid. *This effect is dominant for acids of the same group.*	oxoacid	The greater the number of O atoms attached to the central atom (the greater the oxidation number of the central atom), the stronger the acid.		For the same number of O atoms attached to the central atom, then the greater the electronegativity of the central atom, the stronger the acid.	carboxylic	The greater the electronegativities of the groups attached to the carboxyl group, the stronger the acid.	
*In each diagram, the vertical orange arrow indicates the corresponding increase in acid strength.

Thus, H_2SO_4 is expected to be the stronger acid, as we anticipated.

(c) Both acids have four O atoms bonded to the central atom, but the electronegativity of sulfur is greater than that of phosphorus.

Thus, H_2SO_4 is expected to be the stronger acid.

Self-Test 11.8A For each of the following pairs, predict which acid is stronger: (a) H_2S and HCl; (b) HNO_2 and HNO_3; (c) H_2SO_3 and $HClO_3$.

[***Answer:*** (a) HCl; (b) HNO_3; (c) $HClO_3$]

Self-Test 11.8B List the following carboxylic acids in order of increasing strength: $CHCl_2COOH$, CH_3COOH, and $CH_2ClCOOH$.

The greater the number of oxygen atoms and the more electronegative the atoms present in the molecules of an acid, the stronger the acid. These trends are summarized in Table 11.7.

THE pH OF SOLUTIONS OF WEAK ACIDS AND BASES

The rest of this chapter is a variation on a theme introduced in Chapter 10: the use of equilibrium constants to calculate the equilibrium composition of solutions of acids, bases, and salts. We shall see how to predict the pH of solutions of weak acids and bases and how to calculate the extent of deprotonation of a weak acid and the extent of protonation of a weak base. We shall also see how to calculate the pH of a solution of a salt in which the cation or anion of the salt may itself be a weak acid or base.

11.11 Solutions of Weak Acids

Our first task is to calculate the pH of a solution of a weak acid, such as acetic acid in water. The **initial concentration** of the acid is its concentration as prepared, as if no acid molecules had donated any protons. For a strong acid HA, the H_3O^+ concentration in solution is the same as the initial concentration of the strong acid, because all the HA molecules are deprotonated. However, to find the H_3O^+ concentration in a solution of a weak acid HA, we have to take into account the equilibrium between the acid HA, its conjugate base A^-, and water (Eq. 8). We can expect the pH to be somewhat greater than it would be for a strong acid. The technique, which is based on the use of an equilibrium table like those introduced in Chapter 10, is set out in Toolbox 11.1

The initial concentration is sometimes called either the *analytical concentration* or the *formal concentration (F).*

The calculation summarized in Toolbox 11.1 also allows us to predict the **percentage deprotonation,** the percentage of HA molecules that are deprotonated in the solution:

$$\text{Percentage deprotonated} = \frac{\text{concentration of A}^-}{\text{initial concentration of HA}} \times 100\% \qquad \textbf{(12a)*}$$

To express the percentage deprotonation in terms of the pH of the solution, we use the equality $[H_3O^+] = [A^-]$, which follows from the stoichiometric relation 1 mol $A^- \simeq$ 1 mol H_3O^+ for the deprotonation reaction in Eq. 8. Then

$$\text{Percentage deprotonated} = \frac{[H_3O^+]}{[HA]_{\text{initial}}} \times 100\% \qquad \textbf{(12b)*}$$

A small percentage of deprotonated molecules indicates that the acid HA is very weak.

TOOLBOX 11.1 HOW TO CALCULATE THE pH OF A SOLUTION OF A WEAK ACID

CONCEPTUAL BASIS

Because a proton transfer equilibrium is established as soon as a weak acid is dissolved in water, the concentrations of acid, hydronium ion, and conjugate base of the acid must satisfy the acidity constant of the acid. We can calculate any of these quantities by setting up an equilibrium table like that in Toolbox 10.1.

PROCEDURE

Step 1 Write the chemical equation and K_a for the proton transfer equilibrium. Set up a table with columns labeled by the acid (HA), H_3O^+, and the conjugate base of the acid (A^-). In the first row below the headings, show the initial concentration of each species.

For this step, assume that no acid molecules have been deprotonated.

Step 2 In the second row, write the changes in the concentration needed for the reaction to reach equilibrium.

We do not know the number of acid molecules that lose their protons, and so we assume that the concentration of the acid decreases by x mol·L^{-1} as a result of deprotonation. The reaction stoichiometry gives us the other changes in terms of x.

Step 3 In the third row write the equilibrium concentrations by adding the change in concentration (step 2) to the initial concentration for each substance (step 1).

	Acid, HA	H_3O^+	Conjugate base, A^-
Step 1 Initial concentration	$[HA]_{initial}$	0	0
Step 2 Change in concentration	$-x$	$+x$	$+x$
Step 3 Equilibrium concentration	$[HA]_{initial} - x$	x	x

Although a *change* in concentration may be positive (an increase) or negative (a decrease), the value of the concentration itself must always be positive.

Step 4 Use the value of K_a to calculate the value of x.

The calculation of x can often be simplified, as shown in Toolbox 10.1, by ignoring changes of less than 5% of the initial concentration of the acid. However, at the end of the calculation, we must check that x is consistent with the approximation, by calculating the percentage of acid deprotonated. If this percentage is greater than about 5%, then the exact expression for K_a must be solved for x. An exact calculation requires solving a quadratic equation, as explained in Toolbox 10.1. If the pH is greater than 6, the acid is so dilute or so weak that the autoprotolysis of water contributes significantly to the pH. In such cases, we must use the procedures described in Sections 11.18 and 11.19, which take that autoprotolysis into account. We can ignore the contribution of the autoprotolysis of water in an acidic solution only when the calculated H_3O^+ concentration is substantially (about 10 times) higher than 10^{-7} mol·L^{-1}, corresponding to a pH of 6 or less.

Although we calculate the pH to the number of significant figures appropriate to the data, the answers are often considerably less reliable than that. One reason for this poor reliability is that we are ignoring interactions between the ions in solution.

This procedure is illustrated in Examples 11.7 and 11.8.

EXAMPLE 11.7 Calculating the pH and percentage deprotonation of a weak acid

Calculate the pH and percentage deprotonation of CH_3COOH molecules in 0.080 M $CH_3COOH(aq)$, given that K_a for acetic acid is 1.8×10^{-5}.

Anticipate Because the solution is that of an acid, expect pH < 7. Because the acid is weak, expect only a small percentage deprotonation.

PLAN Following the procedure in Toolbox 11.1, we write the proton transfer equilibrium,

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$

$$K_a = \frac{[H_3O^+][CH_3CO_2^-]}{[CH_3COOH]}$$

and construct the equilibrium table, with concentrations in moles per liter.

What should we assume? There are two assumptions. (1) Deprotonation is so slight that the equilibrium concentration of the acid is approximately the same as its initial concentration. (2) The autoprotolysis of water does not contribute significantly to the pH.

SOLVE First, we set up the equilibrium table:

	Species		
	CH_3COOH	H_3O^+	$CH_3CO_2^-$
Step 1 Initial concentration	0.080	0	0
Step 2 Change in concentration	$-x$	$+x$	$+x$
Step 3 Equilibrium concentration	$0.080 - x$	x	x

Step 4 Substitute the equilibrium concentrations into K_a.

$$K_a = 1.8 \times 10^{-5} = \frac{x \times x}{0.080 - x}$$

Assume that $x \ll 0.080$.

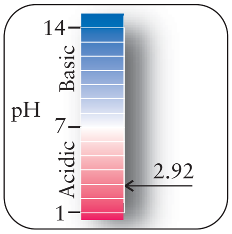
$$1.8 \times 10^{-5} \approx \frac{x^2}{0.080}$$

Solve for x (which must be positive).

$$x \approx \sqrt{0.080 \times (1.8 \times 10^{-5})} = 1.2 \times 10^{-3}$$

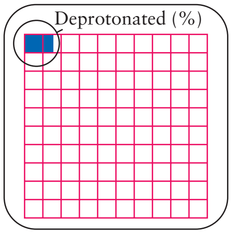
From $x = [H_3O^+]$ and $pH = -\log [H_3O^+]$;

$$pH \approx -\log(1.2 \times 10^{-3})$$
$$= 2.92$$



From percentage deprotonated $= ([H_3O^+]/[HA]_{initial}) \times 100\%$ with $[HA]_{initial} = 0.080$,

$$\text{Percentage deprotonated} = \frac{1.2 \times 10^{-3}}{0.080} \times 100\%$$
$$= 1.5\%$$



Evaluate As anticipated, the pH is less than 7 and the percentage deprotonated is small. The blue square in the grid in the final picture represents the percentage of the acid molecules that are deprotonated. We see that x is less than 5% of 0.10, and the approximation is valid. Because the pH < 6, the assumption that the autoprotolysis of water can be ignored is valid.

Self-Test 11.9A Calculate the pH and percentage deprotonation of 0.50 M aqueous lactic acid. See Table 11.1 for K_a. Be sure to check any approximation to see whether it is valid.

[***Answer:*** 1.69; 4.1%]

Self-Test 11.9B Calculate the pH and percentage deprotonation of 0.22 M aqueous chloroacetic acid. Be sure to check any approximation to see whether it is valid.

EXAMPLE 11.8 Calculating the K_a and pK_a of a weak acid from the pH

The pH of a 0.010 M aqueous solution of mandelic acid, $C_6H_5CH(OH)COOH$, an antiseptic, is 2.95. What are the K_a and pK_a of mandelic acid?

Anticipate Mandelic acid is a carboxylic acid, and so is a weak acid; therefore, expect $K_a \ll 1$.

PLAN Calculate the hydronium ion concentration from the pH and then calculate the value of K_a from the initial concentration of the acid and the hydronium ion concentration.

What should we assume? As in Example 11.7, we assume that the extent of deprotonation is so small that the equilibrium concentration of the acid is approximately the same as its initial concentration; we also assume that the autoprotolysis of water does not contribute significantly to the pH.

SOLVE

From $[H_3O^+] = 10^{-pH}$,

$$[H_3O^+] = 10^{-2.95}\ \text{mol·L}^{-1} = 0.0011\ \text{mol·L}^{-1}$$

Note relations between equilibrium concentrations.

$[H_3O^+] = [A^-]; \quad [HA] = [HA]_{initial} - [H_3O^+]$

Use K_a in the form $K_a = [H_3O^+][A^-]/[HA] = [H_3O^+]^2/([HA]_{initial} - [H_3O^+])$ and substitute the data.

$$K_a = \frac{(0.0011)^2}{0.010 - 0.0011} = 1.4 \times 10^{-4}$$

From $pK_a = -\log K_a$,

$$pK_a = -\log 1.4 \times 10^{-4} = 3.85$$

Evaluate As expected, $K_a \ll 1$.

Self-Test 11.10A The pH of a 0.20 M aqueous solution of crotonic acid, C_3H_5COOH, which is used in medicinal research and in the manufacture of synthetic vitamin A, is 2.69. What is the K_a of crotonic acid?

[***Answer:*** 2.1×10^{-5}]

Self-Test 11.10B The pH of a 0.50 M aqueous solution of the metabolic intermediate homogentisic acid is 2.35. What is the K_a of homogentisic acid, $C_7H_5(OH)_2COOH$?

To calculate the pH and percentage deprotonation of a solution of a weak acid, set up an equilibrium table and determine the H_3O^+ concentration by using the acidity constant.

11.12 Solutions of Weak Bases

In the treatment of weak acids, we found that the percentage deprotonated gave an indication of acid strength. Similarly, when we describe the strengths of weak bases, it is useful to know the **percentage protonated,** the percentage of base molecules that have been protonated:

$$\text{Percentage protonated} = \frac{\text{concentration of HB}^+}{\text{initial concentration of B}} \times 100\%$$

$$= \frac{[HB^+]}{[B]_{initial}} \times 100\% \qquad \textbf{(13)*}$$

Here $[B]_{initial}$ is the initial molar concentration of base, its concentration based on the assumption that no protonation has occurred (its "analytical" or "formal" concentration).

TOOLBOX 11.2 HOW TO CALCULATE THE pH OF A SOLUTION OF A WEAK BASE

CONCEPTUAL BASIS

Proton transfer equilibrium is established as soon as a weak base is dissolved in water, and so we can calculate the hydroxide ion concentration from the initial concentration of the base and the value of its basicity constant. Because the hydroxide ions are in equilibrium with the hydronium ions, we can use the pOH and pK_w to calculate the pH.

PROCEDURE

Step 1 Write the proton transfer equilibrium as in Eq. 9 and set up a table with columns labeled by the base B, its conjugate acid BH^+, and OH^-. In the first row, show the initial concentration of each species.

For the initial values, assume that no base molecules have been protonated.

Step 2 Write the changes in the concentrations that are needed for the reaction to reach equilibrium.

Assume that the concentration of the base decreases by x mol·L^{-1} as a result of protonation. The reaction stoichiometry gives us the other changes in terms of x.

Step 3 Write the equilibrium concentrations by adding the change in concentration (step 2) to the initial concentration for each substance (step 1).

	B	BH^+	OH^-
Step 1 Initial concentration	$[B]_{initial}$	0	0
Step 2 Change in concentration	$-x$	$+x$	$+x$
Step 3 Equilibrium concentration	$[B]_{initial} - x$	x	x

Although a change in concentration may be positive (an increase) or negative (a decrease), the concentration itself must always be positive.

Step 4 Use the value of K_b to calculate the value of x.

The calculation of x can often be simplified, as explained in Toolbox 11.1. We ignore contributions from the autoprotolysis of water to the hydroxide ion concentration if the concentration of hydroxide ions is greater than 10^{-6} mol·L^{-1}.

Step 5 Determine the pOH of the solution and then calculate the pH from the pOH by using Eq. 6b.

This procedure is illustrated in Example 11.9.

As in Toolbox 11.1, although we calculate the pH to the number of significant figures appropriate to the data, the answers are often considerably less reliable than that.

EXAMPLE 11.9 **Calculating the pH and percentage protonation of a weak base**

Calculate the pH and percentage protonation of a 0.20 M aqueous solution of methylamine, CH_3NH_2. The K_b for CH_3NH_2 is 3.6×10^{-4}.

Anticipate Because the amine is a weak base (like all amines), we should expect pH > 7 and only a small percentage protonation.

PLAN Proceed as in Toolbox 11.2.

What should we assume? As in Example 11.7, we make two assumptions. (1) The base is so weak that it undergoes little protonation, so the equilibrium concentration of the base is approximately the same as its initial concentration. (2) The autoprotolysis of water does not contribute significantly to the pH.

SOLVE First, write the proton transfer equilibrium and the corresponding equilibrium table, with all concentrations in moles per liter:

$$H_2O(l) + CH_3NH_2(aq) \rightleftharpoons CH_3NH_3^+(aq) + OH^-(aq) \qquad K_b = \frac{[CH_3NH_3^+][OH^-]}{[CH_3NH_2]}$$

	CH_3NH_2	$CH_3NH_3^+$	OH^-
Step 1 Initial concentration	0.20	0	0
Step 2 Change in concentration	$-x$	$+x$	$+x$
Step 3 Equilibrium concentration	$0.20 - x$	x	x

Step 4 Substitute the equilibrium concentrations into the expression for K_b.

$$K_b = 3.6 \times 10^{-4} = \frac{x \times x}{0.20 - x}$$

Assume that $x \ll 0.20$.

$$3.6 \times 10^{-4} \approx \frac{x^2}{0.20}$$

Solve for x.

$$x \approx \sqrt{0.20 \times (3.6 \times 10^{-4})} = 8.5 \times 10^{-3}$$

Check the assumption that $x \ll 0.20$

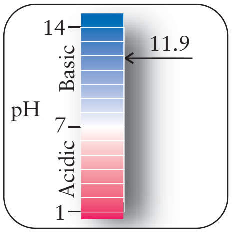
$8.5 \times 10^{-3} \ll 0.20$, so the approximation is valid

From pOH = $-\log[OH^-]$, with $[OH^-] = x$,

$$pOH \approx -\log(8.5 \times 10^{-3}) = 2.07$$

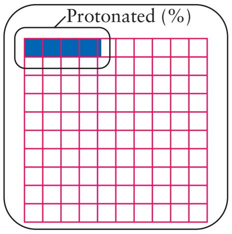
Step 5 From $pH = pK_w - pOH$,

$$pH \approx 14.00 - 2.07$$
$$= 11.93$$



From Eq. 13, with $[HB^+] = x$ and $[B]_{initial} = 0.20$,

$$\text{Percentage protonated} = \frac{8.5 \times 10^{-3}}{0.20} \times 100\%$$
$$= 4.2\%$$



Evaluate As anticipated, the pH is greater than 7 and the percentage protonated is small. That is, 4.2% of the methylamine is present as the protonated form, $CH_3NH_3^+$. Because the pH is greater than 8, the assumption that this equilibrium dominates the pH and that autoprotolysis can be ignored is valid.

Self-Test 11.11A Estimate the pH and percentage of base that has been protonated in 0.15 M NH_2OH(aq), aqueous hydroxylamine.

[***Answer:*** 9.61; 0.027%]

Self-Test 11.11B Estimate the pH and percentage of base that has been protonated in 0.012 M $C_{10}H_{14}N_2$(aq), nicotine.

To calculate the pH of a solution of a weak base, set up an equilibrium table to calculate pOH from the value of K_b and convert that pOH into pH by using pH + pOH = 14.00.

11.13 The pH of Salt Solutions

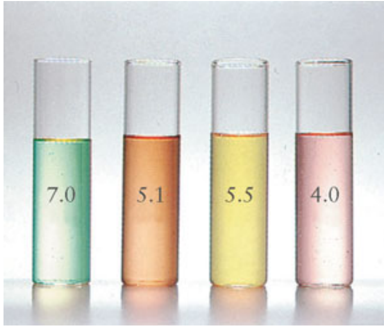


FIGURE 11.19 These four solutions show that hydrated cations can be significantly acidic. The flasks contain, from left to right, pure water, 0.1 M $Al_2(SO_4)_3$(aq), 0.1 M $Ti_2(SO_4)_3$(aq), and 0.1 M CH_3COOH(aq). All four tubes contain a few drops of universal indicator, which changes color from green in a neutral solution through yellow to red with increasing acidity. The superimposed numbers are the pH values of each solution.

We saw in Section J that a salt is produced by the neutralization of an acid by a base. However, if we measure the pH of a solution of a salt, we do not in general find the "neutral" value (pH = 7). For instance, if we neutralize 0.3 M CH_3COOH(aq) with 0.3 M NaOH(aq), the resulting solution of sodium acetate has pH = 9.0. How can this be? The Brønsted–Lowry theory provides the explanation. According to this theory, an ion may be an acid or a base. The acetate ion, for instance, is a base, and the ammonium ion is an acid. The pH of a solution of a salt depends on the relative acidity and basicity of its ions.

Table 11.8 lists some cations that are acidic in water. They fall into four general categories:

- All cations that are the conjugate acids of weak bases produce acidic solutions.

Conjugate acids of weak bases, such as NH_4^+, act as proton donors, and so we can expect them to form acidic solutions.

- Small, highly charged metal cations that can act as Lewis acids in water, such as Al^{3+} and Fe^{3+}, produce acidic solutions, even though the cations themselves have no hydrogen ions to donate (Fig. 11.19).

The protons come from the water molecules that hydrate these metal cations in solution (Fig. 11.20). The water molecules act as Lewis bases and share electrons with the metal cations. This partial loss of electrons weakens the O—H bonds and allows one or more hydrogen ions to be lost from the water molecules. Small, highly charged cations exert the greatest pull on the electrons and so form the most acidic solutions.

- Cations of Group 1 and 2 metals, as well as those of charge +1 from other groups, are such weak Lewis acids that the hydrated ions do not act as acids.

TABLE 11.8 Acidic Character and K_a Values of Common Cations in Water*

Character	Examples	K_a	pK_a
Acidic			
conjugate acids of weak bases	anilinium ion, $C_6H_5NH_3^+$	2.3×10^{-5}	4.64
	pyridinium ion, $C_5H_5NH^+$	5.6×10^{-6}	5.24
	ammonium ion, NH_4^+	5.6×10^{-10}	9.25
	methylammonium ion, $CH_3NH_3^+$	2.8×10^{-11}	10.56
small, highly charged metal cations	Fe^{3+} as $Fe(H_2O)_6^{3+}$	3.5×10^{-3}	2.46
	Cr^{3+} as $Cr(H_2O)_6^{3+}$	1.3×10^{-4}	3.89
	Al^{3+} as $Al(H_2O)_6^{3+}$	1.4×10^{-5}	4.85
	Cu^{2+} as $Cu(H_2O)_6^{2+}$	3.2×10^{-8}	7.49
	Ni^{2+} as $Ni(H_2O)_6^{2+}$	9.3×10^{-10}	9.03
	Fe^{2+} as $Fe(H_2O)_6^{2+}$	8×10^{-11}	10.1
Neutral			
Group 1 and 2 cations	Li^+, Na^+, K^+, Mg^{2+}, Ca^{2+}		
metal cations with charge +1	Ag^+		
Basic	none		

*As in Table 11.1, the experimental pK_a values have more significant figures than shown here, and the K_a values have been calculated from these better data.

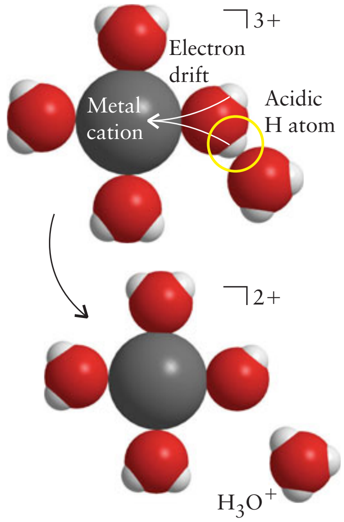

FIGURE 11.20 In water, Al^{3+} cations are hydrated by water molecules that can act as Brønsted acids. Although, for clarity, only four water molecules are shown here, a metal cation typically has six H_2O molecules attached to it. The acidity of the ion arises from the transfer of a hydrogen ion from one of the hydrating water molecules to a water molecule in the solution.

These metal cations are too large or have too low a charge to have an appreciable polarizing effect on the hydrating water molecules that surround them, and so the water molecules do not readily release their protons. These cations are sometimes called "neutral cations," because they have so little effect on the pH.

Notice that no cations are basic. Cations cannot readily accept protons, because the positive charge of the cation repels the positive charge of the incoming protons.

- Very few anions that contain hydrogen produce acidic solutions.

It is difficult for a positively charged proton to leave a negatively charged anion. The few anions that do act as acids include $H_2PO_4^-$ and HSO_4^-.

Table 11.9 summarizes the properties of common anions in solution.

- All anions that are the conjugate bases of weak acids produce basic solutions.

For example, formic acid, HCOOH, the acid in ant venom, is a weak acid, and so the formate ion acts as a base in water:

$$H_2O(l) + HCO_2^-(aq) \rightleftharpoons HCOOH(aq) + OH^-(aq)$$

Formate ions and the other ions listed in the last row of Table 11.9 act as bases in water.

- The anions of strong acids—which include Cl^-, Br^-, I^-, NO_3^-, and ClO_4^-—are such weak bases that they have no significant effect on the pH of a solution.

These anions are considered "neutral" in water.

TABLE 11.9 Acidic and Basic Character of Common Anions in Water

Character	Examples
Acidic	
very few	HSO_4^-, $H_2PO_4^-$
Neutral	
conjugate bases of strong acids	Cl^-, Br^-, I^-, NO_3^-, ClO_4^-
Basic	
conjugate bases of weak acids	F^-, O^{2-}, OH^-, S^{2-}, HS^-, CN^-, CO_3^{2-}, PO_4^{3-}, NO_2^-, $CH_3CO_2^-$, other carboxylate ions

To determine whether the solution of a salt will be acidic, basic, or neutral, we must consider both the cation and the anion. First we examine the anion to see whether it is the conjugate base of a weak acid. If the anion is neither acidic nor basic, we examine the cation to see whether it is an acidic metal ion or the conjugate acid of a weak base. If one ion is an acid and the other a base, as in NH_4F, then the pH is affected by the reactions of both ions with water and both equilibria must be considered, as in Section 11.19.

Self-Test 11.12A Use Tables 11.8 and 11.9 to decide whether aqueous solutions of the salts (a) $Ba(NO_2)_2$; (b) $CrCl_3$; (c) NH_4NO_3 are acidic, neutral, or basic.

[***Answer:*** (a) Basic; (b) acidic; (c) acidic]

Self-Test 11.12B Decide whether aqueous solutions of (a) Na_2CO_3; (b) $AlCl_3$; (c) KNO_3 are acidic, neutral, or basic.

To calculate the pH of a salt solution, we can use the equilibrium table procedure described in Toolboxes 11.1 and 11.2—an acidic cation is treated as a weak acid and a basic anion as a weak base. However, often we must first calculate the K_a or K_b for the acidic or basic ion. Examples 11.10 and 11.11 illustrate the procedure.

EXAMPLE 11.10 Calculating the pH of a salt solution with an acidic cation

Estimate the pH of 0.15 M $NH_4Cl(aq)$.

Anticipate Because NH_4^+ is a weak acid and Cl^- is neutral, we should expect pH < 7.

PLAN We treat the solution as that of a weak acid, using an equilibrium table as in Toolbox 11.1 to calculate the composition and hence the pH. First, write the chemical equation for proton transfer to water and the expression for K_a. Obtain the value of K_a from K_b for the conjugate base by using $K_a = K_w/K_b$ (Eq. 11a). The initial concentration of the acidic cation is equal to the concentration of the cation that the salt would produce if the salt were fully dissociated and the cation retained all its acidic protons.

What should we assume? We make two assumptions. (1) The extent of deprotonation is so small that the concentration of NH_4^+ is insignificantly changed. (2) The autoprotolysis of water does not affect the pH significantly.

SOLVE The equilibrium to consider is

$$NH_4^+(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + NH_3(aq) \qquad K_a = \frac{[H_3O^+][NH_3]}{[NH_4^+]}$$

In Table 11.2, we find $K_b = 1.8 \times 10^{-5}$ for NH_3. First, we construct the following equilibrium table, with all concentrations in moles per liter:

	Species		
	NH_4^+	H_3O^+	NH_3
Step 1 Initial concentration	0.15	0	0
Step 2 Change in concentration	$-x$	$+x$	$+x$
Step 3 Equilibrium concentration	$0.15 - x$	x	x

Step 4 From $K_a = K_w/K_b$,

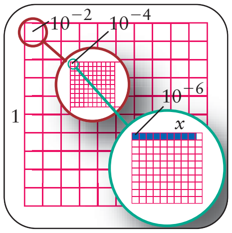
$$K_a = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

Substitute the equilibrium concentrations into the expression for K_a and assume that $x \ll 0.15$:

$$5.6 \times 10^{-10} = \frac{x \times x}{0.15 - x} \approx \frac{x^2}{0.15}$$

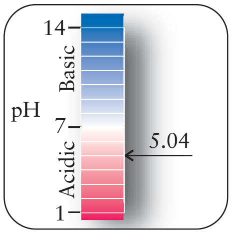
Solve for x.

$$x \approx \sqrt{0.15 \times (5.6 \times 10^{-10})}$$
$$= 9.2 \times 10^{-6}$$



From $pH = -\log [H_3O^+]$ with $[H_3O^+] = x$,

$$pH \approx -\log(9.2 \times 10^{-6})$$
$$= 5.04$$



Evaluate As we anticipated, the pH is less than 7. The approximation that x is less than 5% of 0.15 is valid (by a large margin). Moreover, the H_3O^+ concentration (9.2 μmol·L^{-1}) is substantially larger than that generated by the autoprotolysis of water (0.10 μmol·L^{-1}), and so ignoring the latter contribution is valid (but only just).

Self-Test 11.13A Estimate the pH of 0.10 M CH_3NH_3Cl(aq), aqueous methylammonium chloride; the cation is $CH_3NH_3^+$.

[***Answer:*** 5.78]

Self-Test 11.13B Estimate the pH of 0.10 M NH_4NO_3(aq).

EXAMPLE 11.11 Calculating the pH of a salt solution with a basic anion

Estimate the pH of 0.15 M $Ca(CH_3CO_2)_2$(aq).

Anticipate The $CH_3CO_2^-$ ion is the conjugate base of a weak acid; so the solution will be basic and we should expect pH > 7.

PLAN Use the procedure in Toolbox 11.2, taking the initial concentration of base from the concentration of added salt. Calculate K_b for the basic anion from K_a for its conjugate acid. Convert pOH into pH by using pH + pOH = 14.00.

What should we assume? As in Example 11.10, we need to make two assumptions. (1) Because the protonation of the weak base is so small, the concentration of acetate ions retains its initial value. (2) The autoprotolysis of water does not affect the pH significantly.

SOLVE The proton transfer equilibrium is

$$H_2O(l) + CH_3CO_2^-(aq) \rightleftharpoons CH_3COOH(aq) + OH^-(aq)$$

$$K_b = \frac{[CH_3COOH][OH^-]}{[CH_3CO_2^-]}$$

The initial concentration of $CH_3CO_2^-$ is 2×0.15 mol·L^{-1} = 0.30 mol·L^{-1}, because each formula unit of salt provides two $CH_3CO_2^-$ ions. Table 11.1 gives the K_a of CH_3COOH as 1.8×10^{-5}. First, we construct the equilibrium table:

	$CH_3CO_2^-$	CH_3COOH	OH^-
Step 1 Initial concentration	0.30	0	0
Step 2 Change in concentration	$-x$	$+x$	$+x$
Step 3 Equilibrium concentration	$0.30 - x$	x	x

Step 4 Find the K_b of the $CH_3CO_2^-$ ion from $K_b = K_w/K_a$.

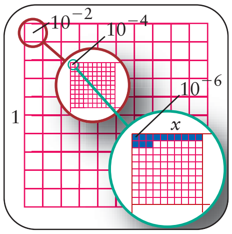
$$K_b = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

Substitute the equilibrium concentrations into the expression for K_b and assume that x is less than 5% of 0.30 (that is, $x < 0.015$).

$$5.6 \times 10^{-10} = \frac{x \times x}{0.30 - x} \approx \frac{x^2}{0.30}$$

Solve for x.

$$x \approx \sqrt{0.30 \times (5.6 \times 10^{-10})}$$
$$= 1.3 \times 10^{-5}$$



Check the assumption that $x < 0.015$.

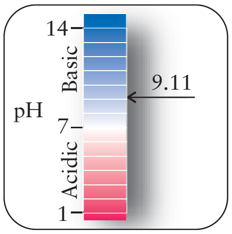
$$1.3 \times 10^{-5} < 0.015$$

From $pOH = -\log[OH^-]$ with $[OH^-] = x$,

$$pOH \approx -\log(1.3 \times 10^{-5}) = 4.89$$

From $pH = pK_w - pOH$,

$$pH \approx 14.00 - 4.89$$
$$= 9.11$$



Evaluate As expected, the pH is greater than 7. The OH^- concentration arising from the proton transfer equilibrium (13 $\mu mol \cdot L^{-1}$) is much larger than that arising from the autoprotolysis of water (0.10 $\mu mol \cdot L^{-1}$), and so it is valid to ignore autoprotolysis.

Self-Test 11.14A Estimate the pH of 0.10 M $KC_6H_5CO_2(aq)$, potassium benzoate; see Table 11.1 for data.

[***Answer:*** 8.59]

Self-Test 11.14B Estimate the pH of 0.020 M KF(aq); see Table 11.1 for data.

Salts that contain the conjugate acids of weak bases produce acidic aqueous solutions; so do salts that contain small, highly charged metal cations. Salts that contain the conjugate bases of weak acids produce basic aqueous solutions.

POLYPROTIC ACIDS AND BASES

A **polyprotic acid** is a compound that can donate more than one proton. Many common acids are polyprotic, including sulfuric acid, H_2SO_4, and carbonic acid, H_2CO_3, each of which can donate two protons, and phosphoric acid, H_3PO_4, which can donate three protons. Polyprotic acids play a critical role in biological systems, because many enzymes can be regarded as polyprotic acids that carry out their vital functions by donating one proton after another. A **polyprotic base** is a species that can accept more than one proton. Examples include the CO_3^{2-} and SO_3^{2-} anions, both of which can accept two protons, and the PO_4^{3-} anion, which can accept three protons.

A polyprotic acid is viewed as donating its protons in a succession of deprotonation steps. For example, a carbonic acid molecule can lose one proton to form HCO_3^-, and then that ion can donate the remaining proton to form CO_3^{2-}. We shall see how to take this succession of deprotonations into account when assessing the pH of the solution of a polyprotic acid or one of its salts. In addition, we shall see how the relative concentrations of the ions in solution, such as PO_4^{3-}, HPO_4^{2-}, and $H_2PO_4^-$, depend on the pH of the solution.

Thinking point: Do you think that successive deprotonations of a polyprotic acid will result in stronger or weaker acids?

11.14 The pH of a Polyprotic Acid Solution

Carbonic acid is an important natural component of the environment because it is formed whenever carbon dioxide dissolves in lake water or seawater. In fact, the oceans provide one of the critical mechanisms for maintaining a constant concentration of carbon dioxide in the atmosphere. Carbonic acid takes part in two successive proton transfer equilibria:

$$H_2CO_3(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq) \qquad K_{a1} = 4.3 \times 10^{-7}$$
$$HCO_3^-(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CO_3^{2-}(aq) \qquad K_{a2} = 5.6 \times 10^{-11}$$

The conjugate base of H_2CO_3 in the first equilibrium, HCO_3^-, acts as an acid in the second equilibrium. That ion produces in turn its own conjugate base, CO_3^{2-}.

Protons are donated successively by polyprotic acids, with the acidity constant decreasing significantly, usually by a factor of about 10^3 or more, with each proton lost (Table 11.10):

$$K_{a1} \gg K_{a2} \gg K_{a3} \gg \cdots$$

The decrease can be traced to the attraction between opposite charges: it is harder to separate a positively charged proton from a negatively charged ion (such as HCO_3^-) than from the original uncharged molecule (H_2CO_3). Sulfuric acid, for example, is a strong acid, but its conjugate base, the hydrogen sulfate ion, HSO_4^-, is a weak acid.

Sulfuric acid is the only common polyprotic acid for which the first deprotonation is complete. The second deprotonation adds to the H_3O^+ concentration slightly, and so the overall pH will be slightly lower than that due to the first deprotonation alone. For example, in 0.010 M $H_2SO_4(aq)$ the first deprotonation is complete:

$$H_2SO_4(aq) + H_2O(l) \longrightarrow H_3O^+(aq) + HSO_4^-(aq)$$

It results in an H_3O^+ concentration equal to the initial concentration of the acid, 0.010 $mol{\cdot}L^{-1}$. This value corresponds to pH = 2.0. However, the conjugate base, HSO_4^-, also contributes protons to the solution, and so the second proton transfer equilibrium needs to be taken into account:

$$HSO_4^-(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + SO_4^{2-}(aq) \qquad K_{a2} = 0.012$$

Therefore, to calculate the pH of a solution of sulfuric acid, we set up an equilibrium table in which the initial concentrations are those due to the first deprotonation: $[HSO_4^-] = 0.010\ mol{\cdot}L^{-1}$, $[H_3O^+] = 0.010\ mol{\cdot}L^{-1}$, and $[SO_4^{2-}] = 0$. Then we solve for the new value of the hydronium ion concentration:

$$K_{a2} = \frac{[H_3O^+][SO_4^{2-}]}{[HSO_4^-]} \qquad 0.012 = \frac{(0.010 + x) \times x}{0.010 - x}$$

In this way, we find $x = 4.3 \times 10^{-3}$, $[H_3O^+] = 0.014\ mol{\cdot}L^{-1}$, and pH = 1.9, which is slightly lower than the pH = 2.0 that we calculated on the basis of the first deprotonation alone.

TABLE 11.10 Acidity Constants of Polyprotic Acids

Acid	K_{a1}	pK_{a1}	K_{a2}	pK_{a2}	K_{a3}	pK_{a3}
sulfuric acid, H_2SO_4	strong		1.2×10^{-2}	1.92		
oxalic acid, $(COOH)_2$	5.9×10^{-2}	1.23	6.5×10^{-5}	4.19		
sulfurous acid, H_2SO_3	1.5×10^{-2}	1.81	1.2×10^{-7}	6.91		
phosphorous acid, H_3PO_3	1.0×10^{-2}	2.00	2.6×10^{-7}	6.59		
phosphoric acid, H_3PO_4	7.6×10^{-3}	2.12	6.2×10^{-8}	7.21	2.1×10^{-13}	12.68
tartaric acid, $C_2H_4O_2(COOH)_2$	6.0×10^{-4}	3.22	1.5×10^{-5}	4.82		
carbonic acid, H_2CO_3	4.3×10^{-7}	6.37	5.6×10^{-11}	10.25		
hydrosulfuric acid, H_2S	1.3×10^{-7}	6.89	7.1×10^{-15}	14.15		

Self-Test 11.15A Estimate the pH of 0.050 M $H_2SO_4(aq)$.

[*Answer:* 1.23]

Self-Test 11.15B Estimate the pH of 0.10 M $H_2SO_4(aq)$.

If values of K_{a1} and K_{a2} for a polyprotic acid are close together, then the calculations are more complicated, as both equilibria must be considered.

The parent acids of common polyprotic acids other than sulfuric are weak and the acidity constants of successive deprotonation steps are normally widely different. As a result, except for sulfuric acid, to calculate the pH of a polyprotic acid, we just use K_{a1} and take only the first deprotonation into account; that is, we treat the acid as a monoprotic weak acid (see Toolbox 11.1). Subsequent deprotonations do take place, but provided K_{a2} is less than about $K_{a1}/1000$, they do not affect the pH significantly and can be ignored.

Estimate the pH of a polyprotic acid for which all deprotonations are weak by using only the first deprotonation equilibrium and assuming that further deprotonation is insignificant. An exception is sulfuric acid, the only common polyprotic acid that is a strong acid in its first deprotonation.

11.15 Solutions of Salts of Polyprotic Acids

Exceptions are HSO_4^-, which is an extremely weak base, and HPO_3^{2-}, which does not act as an acid because its proton is not acidic (Section 11.10).

The conjugate base of a polyprotic acid is amphiprotic: it can act as either an acid or a base because it can either donate its remaining acidic hydrogen atom as a proton or accept a proton and revert to the original acid. For example, a hydrogen sulfide ion, HS^-, in water acts as both an acid and a base:

$$HS^-(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + S^{2-}(aq) \qquad K_{a2} = 7.1 \times 10^{-15} \qquad pK_{a2} = 14.15$$

$$HS^-(aq) + H_2O(l) \rightleftharpoons H_2S(aq) + OH^-(aq) \qquad K_{b1} = K_w/K_{a1} = 7.7 \times 10^{-8} \qquad pK_{b1} = 7.11$$

Because HS^- is amphiprotic, it is not immediately apparent whether an aqueous solution of NaHS will be acidic or basic. However, we can use the pK_a and pK_b values of the HS^- ion to conclude that:

- HS^- is such a weak acid that the basic character of S^{2-} will dominate, and $pH > 7$.
- HS^- is a weak base; again $pH > 7$.

The first conclusion arises from the large pK_{a2} of H_2S. The second conclusion arises from pK_{b1} having an intermediate value and therefore (by the relation in Eq. 11b) the pK_{a1} of H_2S also having an intermediate value. This reasoning suggests that the pH will be high if both pK_{a1} and pK_{a2} are relatively large. Indeed, if we make some reasonable assumptions we can use

$$pH = \tfrac{1}{2}(pK_{a1} + pK_{a2}) \qquad \textbf{(14)*}$$

This formula is reliable provided $S \gg K_w/K_{a2}$ and $S \gg K_{a1}$, where S is the initial (that is, analytical or formal) concentration of the salt. If these criteria are not satisfied, a much more complicated expression must be used: it and its derivation, including the derivation of this simplified version, can be found on the Web site for this text.

EXAMPLE 11.12 Estimating the pH of a solution of an amphiprotic salt

Estimate the pH of (a) 0.20 M $NaH_2PO_4(aq)$; (b) 0.20 M $Na_2HC_6H_5O_7(aq)$, a salt of citric acid, $H_3C_6H_5O_7$. For citric acid, $pK_{a2} = 5.95$, and $pK_{a3} = 6.39$.

PLAN Use Eq. 14 to determine the pH of the salts of the diprotic conjugate base (H_2A^-) of a triprotic acid (H_3A) and the monoprotic conjugate base (HA^-) of a diprotic acid (H_2A). However, when the solute is a salt of an anion that has lost two protons, such as $HC_6H_5O_7^{2-}$, we must adjust the expression to use the appropriate neighboring pK_as.

What should we assume? We need to verify that $S \gg K_w/K_{a2}$ and $S \gg K_{a1}$.

SOLVE (a) For H_3PO_4, $K_{a1} = 7.6 \times 10^{-3}$ and $K_{a2} = 6.2 \times 10^{-8}$, and so $pK_{a1} = 2.12$ and $pK_{a2} = 7.21$. Therefore, for the solution of $H_2PO_4^-$,

Check that $S \gg K_w/K_{a2}$ and $S \gg K_{a1}$.

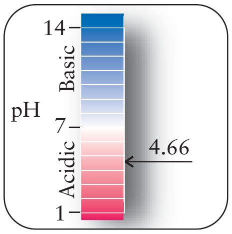
$$S = 0.20, \quad \frac{K_w}{K_{a2}} = \frac{1.0 \times 10^{-14}}{6.2 \times 10^{-8}} = 1.6 \times 10^{-7}, \quad \text{so } S \gg \frac{K_w}{K_{a2}}$$

$$S = 0.20, \quad K_{a1} = 7.6 \times 10^{-3}, \quad \text{so } S \gg K_{a1}$$

Therefore, the use of Eq. 14 is valid.

From $\text{pH} = \frac{1}{2}(\text{p}K_{a1} + \text{p}K_{a2})$,

$$\text{pH} = \tfrac{1}{2}(2.12 + 7.21)$$
$$= 4.66$$



(b) For citric acid, $\text{p}K_{a2} = 5.95$ and $\text{p}K_{a3} = 6.39$. Therefore, for the solution of $HC_6H_5O_7^{2-}$,

Check that $S \gg K_w/K_{a3}$ and $S \gg K_{a2}$.

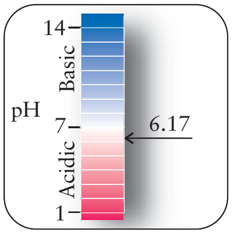
$$S = 0.20, \quad \frac{K_w}{K_{a3}} = \frac{1.0 \times 10^{-14}}{4.1 \times 10^{-7}} = 2.4 \times 10^{-8}, \quad \text{so } S \gg \frac{K_w}{K_{a3}}$$

$$S = 0.20, \quad K_{a2} = 1.1 \times 10^{-6}, \quad \text{so } S \gg K_{a2}$$

Therefore, the use of Eq. 14 is valid.

From $\text{pH} = \frac{1}{2}(\text{p}K_{a2} + \text{p}K_{a3})$,

$$\text{pH} = \tfrac{1}{2}(5.95 + 6.39)$$
$$= 6.17$$



Self-Test 11.16A Estimate the pH of 0.10 M $NaHCO_3(aq)$.

[***Answer:*** 8.31]

Self-Test 11.16B Estimate the pH of 0.50 M $KH_2PO_4(aq)$.

Suppose we need to estimate the pH of an aqueous solution of a fully deprotonated polyprotic acid molecule. An example is a solution of sodium sulfide, in which sulfide ions, S^{2-}, are present; another example is a solution of potassium phosphate, which contains PO_4^{3-} ions. In such a solution, the anion acts as a base: it accepts protons from water. For such a solution, we can use the techniques for calculating the pH of a basic anion illustrated in Example 11.11. The K_a to use in the calculation is for the deprotonation that produces the ion being studied. For S^{2-}, we would use K_{a2} for H_2S; and for PO_4^{3-}, we would use K_{a3} for H_3PO_4.

The pH of the aqueous solution of an amphiprotic salt can be estimated from the average of the pK$_a$s of the salt and its conjugate acid. The pH of a solution of a salt of the final conjugate base of a polyprotic acid is found from the reaction of the anion with water.

11.16 The Concentrations of Solute Species

Environmental chemists studying the pollution caused by fertilizers in runoff from fields or mineralogists studying the formation of sedimentary rocks as groundwater trickles through rock formations may need to know not only the pH but also the concentrations of each of the ions present in the solution. For example, they may need to

know the concentration of sulfite ion in a solution of sulfurous acid or the concentrations of phosphate and hydrogen phosphate ions in a solution of phosphoric acid. The calculations described in Toolbox 11.1 tell us the pH—the hydrogen ion concentration—but for a polyprotic acid they do not give the concentrations of all the solute species in solution, which for H_3PO_4 includes H_3PO_4, $H_2PO_4^-$, HPO_4^{2-}, and PO_4^{3-}. To calculate them, we need to take into account all the proton transfer equilibria taking place in the solution.

To simplify the calculations, we start by judging the relative concentration of each species in solution and identify terms that can be ignored. To make this judgment, we use the general rule that concentrations of species present in the greater amount are not significantly affected by concentrations of species present in the smaller amount, especially if the difference in concentrations is large.

TOOLBOX 11.3 HOW TO CALCULATE THE CONCENTRATIONS OF ALL SPECIES IN A POLYPROTIC ACID SOLUTION

CONCEPTUAL BASIS

We assume that the polyprotic acid is the solute species present in largest amount. We also assume that only the first deprotonation contributes significantly to $[H_3O^+]$ and that the autoprotolysis of water does not contribute significantly to $[H_3O^+]$ or $[OH^-]$.

PROCEDURE FOR A DIPROTIC ACID

Step 1 From the deprotonation equilibrium of the acid (H_2A), determine the concentrations of the conjugate base (HA^-) and H_3O^+, as illustrated in Example 11.7.

Step 2 Find the concentration of A^{2-} from the second deprotonation equilibrium (that of HA^-) by substituting the concentrations of H_3O^+ and HA^- from step 1 into the expression for K_{a2}.

Step 3 Find the concentration of OH^- by dividing K_w by the concentration of H_3O^+.

PROCEDURE FOR A TRIPROTIC ACID

Step 1 From the deprotonation equilibrium of the acid (H_3A), determine the concentrations of the conjugate base (H_2A^-) and H_3O^+.

Step 2 Find the concentration of HA^{2-} from the second deprotonation equilibrium (that of H_2A^-) by substituting the concentrations of H_3O^+ and H_2A^- from step 1 into the expression for K_{a2}.

Step 3 Find the concentration of A^{3-} from the deprotonation equilibrium of HA^{2-} by substituting the concentrations of H_3O^+ and HA^{2-} from step 2 into the expression for K_{a3}. The concentration of H_3O^+ is the same in all three calculations because only the first deprotonation makes a significant contribution to its value.

Step 4 Find the concentration of OH^- by dividing K_w by the concentration of H_3O^+.

This procedure is illustrated in Example 11.13.

EXAMPLE 11.13 Calculating the concentrations of all solute species in a polyprotic acid solution

Calculate the concentrations of all solute species in 0.10 M H_3PO_4(aq).

Anticipate Because successive deprotonations result in ever weaker acids, we expect the concentrations to lie in the order $H_3PO_4 > H_2PO_4^- > HPO_4^{2-} > PO_4^{3-}$, with very, very little of the completely deprotonated species.

PLAN Follow the procedure in Toolbox 11.3.

What should we assume? That only the first deprotonation affects the pH and that the autoprotolysis of water has no significant effect on the pH.

SOLVE

Step 1 The primary proton transfer equilibrium is

$$H_3PO_4(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + H_2PO_4^-(aq)$$

and the first acidity constant, from Table 11.10, is 7.6×10^{-3}. The equilibrium table, with the concentrations in moles per liter, is

	H_3PO_4	H_3O^+	$H_2PO_4^-$
Initial concentration	0.10	0	0
Change in concentration	$-x$	$+x$	$+x$
Equilibrium concentration	$0.10 - x$	x	x

From $K_{a1} = [H_3O^+][H_2A^-]/[H_3A]$, assuming that $x \ll 0.10$, decide if it is valid to approximate the expression.

$$K_{a1} = 7.6 \times 10^{-3} = \frac{x \times x}{0.10 - x} \approx \frac{x^2}{0.10}$$

solves to $x \approx 0.028$, which is 28% of 0.10, too large for the approximation.

Because the value of x is in fact larger than 5% of 0.10, we must use the full quadratic equation.

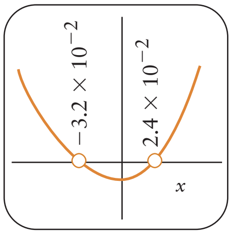
$$(7.6 \times 10^{-3}) \times (0.10 - x) = x^2$$

Rearrange the equation.

$$x^2 + (7.6 \times 10^{-3})x - 7.6 \times 10^{-4} = 0$$

Solve for x with the quadratic formula.

$$x = 2.4 \times 10^{-2} \text{ or } -3.2 \times 10^{-2}$$

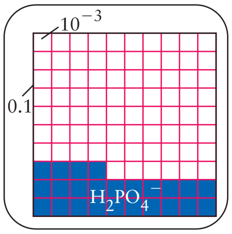


Reject the negative root.

$$x = 2.4 \times 10^{-2}; \text{ therefore, } [H_3O^+] = 2.4 \times 10^{-2}\ \text{mol·L}^{-1}$$

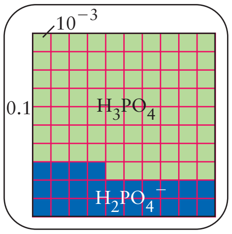
From $[H_2PO_4^-] = [H_3O^+]$,

$$[H_2PO_4^-] = 2.4 \times 10^{-2}\ \text{mol·L}^{-1}$$



It follows from the equilibrium table that

$$[H_3PO_4] \approx 0.10 - 0.024\ \text{mol·L}^{-1}$$
$$= 0.08\ \text{mol·L}^{-1}\ (0.076 \text{ rounded to } 0.08)$$



The little illustrations display the percentage composition of species in the solution: blue for $H_2PO_4^-$, green for H_3PO_4, and (below) yellow for HPO_4^{2-}.

Step 2 Now we use $K_{a2} = 6.2 \times 10^{-8}$ to find the concentration of HPO_4^{2-}. Because $K_{a2} \ll K_{a1}$, we can safely assume that the H_3O^+ concentration calculated in step 1 is unchanged by the second deprotonation. The proton transfer equilibrium is

$$H_2PO_4^-(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + HPO_4^{2-}(aq)$$

We set up the equilibrium table with concentrations in moles per liter, using the results from step 1 for the concentrations of H_3O^+ and $H_2PO_4^-$:

	$H_2PO_4^-$	H_3O^+	HPO_4^{2-}
Initial concentration (from step 1)	2.4×10^{-2}	2.4×10^{-2}	0
Changes in concentration	$-x$	$+x$	$+x$
Equilibrium concentration	$2.4 \times 10^{-2} - x$	$2.4 \times 10^{-2} + x$	x

From $K_{a2} = [H_3O^+][HA^{2-}]/[H_2A^-]$, assuming that $x \ll 2.4 \times 10^{-2}$.

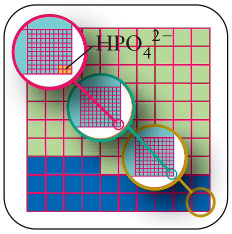
$$K_{a2} = 6.2 \times 10^{-8} = \frac{(2.4 \times 10^{-2} + x) \times x}{2.4 \times 10^{-2} - x} \approx \frac{2.4 \times 10^{-2} \times x}{2.4 \times 10^{-2}} = x$$

Check the assumption that $x \ll 2.4 \times 10^{-2}$.

$$6.2 \times 10^{-8} \ll 2.4 \times 10^{-2}$$

From $[HPO_4^{2-}] = x \approx K_{a2}$,

$$[HPO_4^{2-}] = 6.2 \times 10^{-8}\ mol{\cdot}L^{-1}$$



Step 3 The loss of the final proton from HPO_4^{2-} produces the phosphate ion, PO_4^{3-}:

$$HPO_4^{2-}(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + PO_4^{3-}(aq)$$

The equilibrium constant is $K_{a3} = 2.1 \times 10^{-13}$, a very small value. We assume that the concentration of H_3O^+ calculated in step 1 and the concentration of HPO_4^{2-} calculated in step 2 are unaffected by the additional deprotonation. The equilibrium table is

	HPO_4^{2-}	H_3O^+	PO_4^{3-}
Initial concentration (from step 2)	6.2×10^{-8}	2.4×10^{-2}	0
Changes in concentration	$-x$	$+x$	$+x$
Equilibrium concentration	$6.2 \times 10^{-8} - x$	$2.4 \times 10^{-2} + x$	x

From $K_{a3} = [H_3O^+][A^{3-}]/[HA^{2-}]$; because K_{a3} is so small, assume that $x \ll 6.2 \times 10^{-8}$ and simplify the equation.

$$K_{a3} = 2.1 \times 10^{-13} = \frac{(2.4 \times 10^{-2} + x) \times x}{6.2 \times 10^{-8} - x} \approx \frac{2.4 \times 10^{-2} \times x}{6.2 \times 10^{-8}}$$

Solve for x.

$$x \approx \frac{(2.1 \times 10^{-13}) \times (6.2 \times 10^{-8})}{2.4 \times 10^{-2}} = 5.4 \times 10^{-19}$$

From $[PO_4^{3-}] = x$,

$$[PO_4^{3-}] \approx 5.4 \times 10^{-19}\ mol{\cdot}L^{-1}$$

Step 4 From $[OH^-] = K_w/[H_3O^+]$,

$$[OH^-] = \frac{1.0 \times 10^{-14}}{2.4 \times 10^{-2}} = 4.2 \times 10^{-13}$$

At this point, we can summarize the concentrations of all the solute species in 0.10 M $H_3PO_4(aq)$ in order of decreasing concentration:

Species:	H_3PO_4	H_3O^+	$H_2PO_4^-$	HPO_4^{2-}	OH^-	PO_4^{3-}
Concentration ($mol{\cdot}L^{-1}$):	0.08	2.4×10^{-2}	2.4×10^{-2}	6.2×10^{-8}	4.2×10^{-13}	5.4×10^{-19}

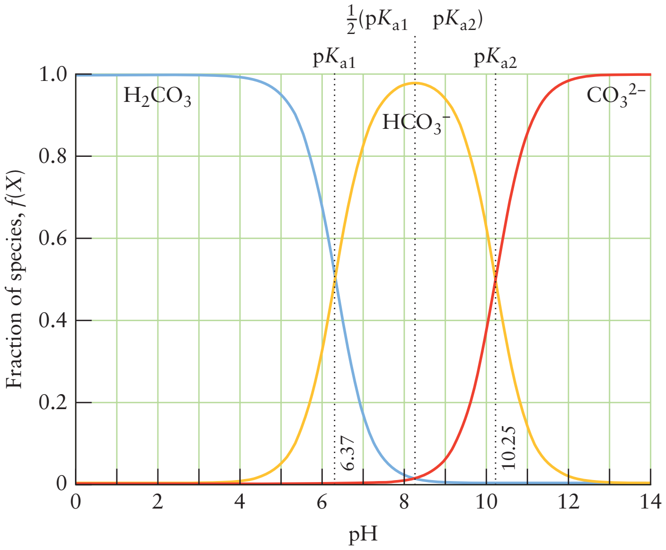


FIGURE 11.21 The fractional composition of the species in carbonic acid as a function of pH. Note that the more fully protonated species are dominant at lower pH.

Living Graph 11.21

Evaluate We can conclude that the second deprotonation proceeds only to a small extent. The HPO_4^{2-} ion is deprotonated only to a very tiny extent, too small to illustrate with a diagram, and our assumption that H_3O^+ is unaffected by the third deprotonation is justified.

Self-Test 11.17A Calculate the concentrations of all solute species in 0.20 M H_2S(aq).

[***Answer:*** With concentrations in mol·L^{-1}: H_2S, 0.20; HS^-, 1.6×10^{-4}; H_3O^+, 1.6×10^{-4}; OH^-, 6.2×10^{-11}; S^{2-}, 7.1×10^{-15}]

Self-Test 11.17B Protonated glycine ($^+NH_3CH_2COOH$) is a diprotic amino acid with $K_{a1} = 4.5 \times 10^{-3}$ and $K_{a2} = 1.7 \times 10^{-10}$. Calculate the concentrations of all solute species in 0.50 M $NH_3CH_2COOHCl$(aq).

The concentrations of all species in a solution of a polyprotic acid can be calculated by assuming that species present in smaller amounts do not affect the concentrations of species present in larger amounts.

11.17 Composition and pH

Sometimes we need to know how the concentrations of the ions present in a solution of a polyprotic acid vary with pH. This information is particularly important in the study of natural waters, such as rivers and lakes (Box 11.1). For example, if we were examining carbonic acid in rainwater, then, at low pH (when hydronium ions are abundant), we would expect the fully protonated species (H_2CO_3) to be dominant; at high pH (when hydroxide ions are abundant), we expect the fully deprotonated species (CO_3^{2-}) to be dominant; at intermediate pH, we expect the intermediate species (HCO_3^-, in this case) to be dominant (Fig. 11.21). We can verify these expectations quantitatively.

HOW DO WE DO THAT?

To see how the concentrations of species present in a solution vary with pH, we take the carbonic acid system as an example. Consider the following proton transfer equilibria:

$$H_2CO_3(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq) \qquad K_{a1} = \frac{[H_3O^+][HCO_3^-]}{[H_2CO_3]}$$

$$HCO_3^-(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CO_3^{2-}(aq) \qquad K_{a2} = \frac{[H_3O^+][CO_3^{2-}]}{[HCO_3^-]}$$

We can express the composition of the solution in terms of the fraction, $f(X)$, of each species X present, where X could be H_2CO_3, HCO_3^-, or CO_3^{2-}, and

$$f(X) = \frac{[X]}{[H_2CO_3] + [HCO_3^-] + [CO_3^{2-}]}$$

BOX 11.1 WHAT HAS THIS TO DO WITH . . . THE ENVIRONMENT?

Acid Rain and the Gene Pool

The human impact on the environment affects many areas of our lives and future. One example is the effect of acid rain on *biodiversity*, the diversity of living things. In the prairies that extend across the heartlands of North America and Asia, native plants have evolved that can survive even nitrogen-poor soil and drought. By studying prairie plants, scientists hope to breed food plants that will be hardy sources of food in times of drought. However, acid rain is making some of these plants extinct.

Eastern gama grass is a variety of a prairie plant that produces seeds rich in protein. It is the subject of sustainable agriculture research because it produces an abundance of seeds and yet is a perennial plant that is resistant to drought.

Acid rain is a regional phenomenon. The areas in different colors on the map shown here indicate constant values of the pH of rain. Notice that the pH of rain decreases downwind (generally, east) of heavily populated areas. The low pH in heavily industrialized and populated areas is caused by the acidic oxides sulfur dioxide, SO_2, and the nitrogen oxides, NO and NO_2.

Rain unaffected by human activity contains mostly weak acids and has a pH of about 5.7. The primary acid present is carbonic acid, H_2CO_3, a weak acid that results when atmospheric carbon dioxide dissolves in water. The major pollutants in acid rain are strong acids that arise from human activities. Atmospheric nitrogen and oxygen can react to form NO, but the endothermic reaction is spontaneous only at the high temperatures of automobile internal combustion engines and electrical power stations:

$$N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$$

Nitric oxide, NO, is not very soluble in water, but it can be oxidized further in air to form nitrogen dioxide:

$$2\ NO(g) + O_2(g) \longrightarrow 2\ NO_2(g)$$

The NO_2 reacts with water, forming nitric acid and nitric oxide:

$$3\ NO_2(g) + 3\ H_2O(l) \longrightarrow 2\ H_3O^+(aq) + 2\ NO_3^-(aq) + NO(g)$$

The catalytic converters now used in automobiles can reduce NO to harmless N_2. They are required in the United States for all new cars and trucks (see Section 14.15).

It will turn out to be helpful to express $f(X)$ in terms of the ratio of each species to the intermediate species, HCO_3^-. So we divide the numerator and denominator by $[HCO_3^-]$ and get

$$f(X) = \frac{[X]/[HCO_3^-]}{[H_2CO_3]/[HCO_3^-] + 1 + [CO_3^{2-}]/[HCO_3^-]}$$

All three concentration ratios can be written in terms of the hydronium ion concentration. We simply rearrange the expressions for the first and second acidity constants:

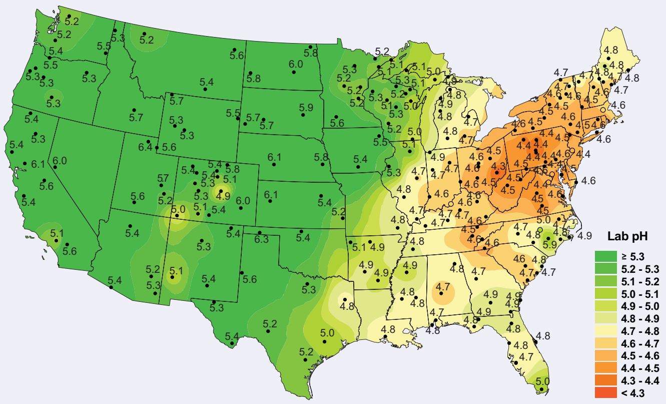
$$\frac{[H_2CO_3]}{[HCO_3^-]} = \frac{[H_3O^+]}{K_{a1}}; \quad \frac{[CO_3^{2-}]}{[HCO_3^-]} = \frac{K_{a2}}{[H_3O^+]}$$

then substitute them into the expression for $f(X)$ and rearrange it to obtain:

$$f(H_2CO_3) = \frac{[H_3O^+]^2}{[H_3O^+]^2 + [H_3O^+]K_{a1} + K_{a1}K_{a2}}$$

$$f(HCO_3^-) = \frac{[H_3O^+]K_{a1}}{[H_3O^+]^2 + [H_3O^+]K_{a1} + K_{a1}K_{a2}},$$

$$f(CO_3^{2-}) = \frac{K_{a1}K_{a2}}{[H_3O^+]^2 + [H_3O^+]K_{a1} + K_{a1}K_{a2}}$$



Precipitation over North America gradually becomes more acidic from west to east, especially in industrialized areas of the Northeast. This acid rain may be a result of the release of nitrogen and sulfur oxides into the atmosphere. The colors and numbers (see key) indicate pH measured at field laboratories in 2007. Additional maps may be found on the National Atmospheric Deposition Program/National Trends Network web site, http://nadp.sws.uiuc.edu/isopleths/annualmaps.asp.

Sulfur dioxide is produced as a by-product of the burning of fossil fuels. It may combine with water directly to form sulfurous acid, a weak acid:

$$SO_2(g) + H_2O(l) \longrightarrow H_2SO_3(aq)$$

Alternatively, in the presence of particulate matter and aerosols, sulfur dioxide may react with atmospheric oxygen to form sulfur trioxide, which forms sulfuric acid, a strong acid, in water:

$$2\,SO_2(g) + O_2(g) \longrightarrow 2\,SO_3(g)$$

$$SO_3(g) + 2\,H_2O(l) \longrightarrow H_3O^+(aq) + HSO_4^-(aq)$$

Acid rain affects plants by changing the conditions in the soil. For example, nitric acid deposits nitrates, which fertilize the land. The nitrates allow fast-growing weeds such as quack grass to replace valuable prairie species. If these species were to become extinct, their genetic material would no longer be available for agricultural research.

Research on air pollution is complex. Forests and prairies cover vast areas, and the interplay of regional air pollutants is so subtle that it may take years to sort out all the environmental stresses. Controls being put in place are beginning to reduce the acidity of rain in North America and Europe. However, biologists have found that they are not enough for some sensitive environments. More stringent controls may be needed for us to maintain our quality of life without losing our precious heritage of native plants. We can also help by using automobiles less and bicycles more or by using public transportation when we can.

Environment Canada, "Acid rain," http://www.ec.gc.ca/acidrain/.

We have found expressions for the fractions, f, of species in a solution of carbonic acid. They are easily generalized to any diprotic acid H_2A:

$$f(H_2A) = \frac{[H_3O^+]^2}{H}, \quad f(HA^-) = \frac{[H_3O^+]K_{a1}}{H}, \quad f(A^{2-}) = \frac{K_{a1}K_{a2}}{H} \qquad \textbf{(15a)}$$

where

$$H = [H_3O^+]^2 + [H_3O^+]K_{a1} + K_{a1}K_{a2} \qquad \textbf{(15b)}$$

What do these equations tell us? At high pH, the concentration of hydronium ions is very low; therefore the numerators in $f(H_2A)$ and $f(HA^-)$ are very small, and so these species are in very low abundance, as we expected. At low pH, the concentration of hydronium ions is high; therefore the numerator in $f(H_2A)$ is large, and this species dominates.

The shapes of the curves predicted by Eq. 15 are shown for H_2CO_3 in Fig. 11.21. We see that $f(HCO_3^-) \approx 1$ at intermediate pH. The maximum value of $f(HCO_3^-)$ is at

$$pH = \tfrac{1}{2}(pK_{a1} + pK_{a2})$$

Note that the fully protonated form (H_2CO_3) is dominant when $pH < pK_{a1}$ and the fully deprotonated form (CO_3^{2-}) becomes dominant when $pH > pK_{a2}$. Similar calculations can be carried out for triprotic acids (Fig. 11.22).

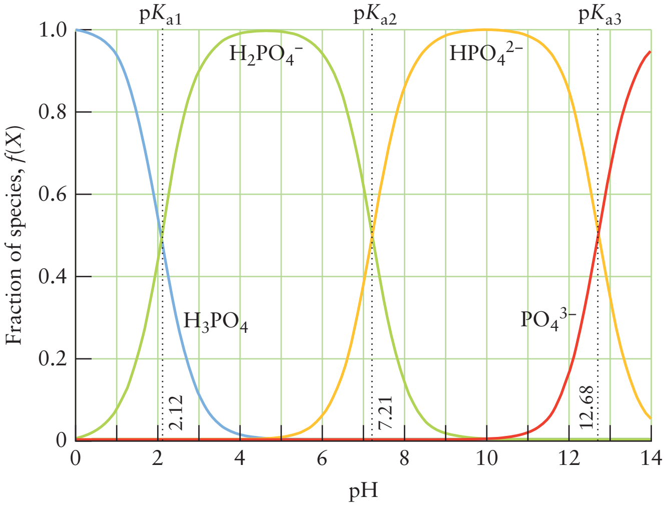

FIGURE 11.22 The fractional composition of the species in phosphoric acid as a function of pH. As in Fig. 11.20, the more fully protonated the species, the lower the pH at which it is dominant.

Thinking point: The expressions in Eq. 15 have a symmetry. Can you identify it and use it to write down the corresponding expression for a triprotic acid?

The fraction of deprotonated species increases as the pH is increased, as summarized in Figs. 11.21 and 11.22.

AUTOPROTOLYSIS AND pH

Suppose we were asked to estimate the pH of 1.0×10^{-8} M HCl(aq). If we used the techniques of Example 11.3 to calculate the pH from the concentration of the acid itself, we would find pH = 8.00. That value, though, is absurd, because it lies on the basic side of neutrality, whereas HCl is an acid! The error stems from there being two sources of hydronium ions, whereas we have considered only one. At very low acid concentrations, the supply of hydronium ions from the autoprotolysis of water is close to the supply provided by the very low concentration of HCl, and both supplies must be taken into account. The following two sections explain how to take autoprotolysis into account, first for strong acids and bases and then for weak ones.

11.18 Very Dilute Solutions of Strong Acids and Bases

We have to include the contribution of autoprotolysis to pH only when the concentration of strong acid or base is less than about 10^{-6} mol·L^{-1}. To calculate the pH in such a case, we need to consider all species in solution. As an example, consider a solution of HCl, a strong acid. Other than water, the species present are H_3O^+, OH^-, and Cl^-. There are three unknown concentrations. To find them, we need three equations.

If an ion is doubly charged, we multiply its concentration by 2 in the charge-balance equation, and by 3 for triply charged ions.

The first equation takes **charge balance** into account, the requirement that the solution must be electrically neutral overall. That is, the concentration of cations must equal that of anions. Because there is only one type of cation, H_3O^+, the concentration of H_3O^+ ions must equal the sum of the concentrations of the two types of anions, Cl^- and OH^-. The charge-balance relation $[H_3O^+] = [Cl^-] + [OH^-]$ then tells us that

$$[OH^-] = [H_3O^+] - [Cl^-]$$

The second equation takes **material balance** into account, the requirement that all the added solute must be accounted for even though it is now present as ions. Because HCl is a strong acid, the concentration of Cl^- ions in the solution is equal to the concentration of the HCl added initially (all the HCl molecules are deprotonated). If we denote the numerical value of that initial concentration by $[HCl]_{initial}$, the material-balance relation is $[Cl^-] = [HCl]_{initial}$. We can combine it with the preceding equation to write

$$[OH^-] = [H_3O^+] - [HCl]_{initial}$$

The third equation is the expression for the autoprotolysis constant, K_w (Eq. 1). We can substitute the preceding expression for $[OH^-]$ into the expression for K_w:

$$K_w = [H_3O^+][OH^-] = [H_3O^+]([H_3O^+] - [HCl]_{initial})$$

and rearrange it into a quadratic equation:

$$[H_3O^+]^2 - [HCl]_{initial}[H_3O^+] - K_w = 0 \qquad (16)$$

As shown in Example 11.14, we can use the quadratic formula to solve this equation for the concentration of hydronium ions.

Now consider a very dilute solution of a strong base, such as NaOH. Apart from water, the species present in solution are Na^+, OH^-, and H_3O^+. As we did for HCl, we can write down three equations relating the concentrations of these ions by using charge balance, material balance, and the autoprotolysis constant. Because the cations present are hydronium ions and sodium ions, the charge-balance relation is

$$[OH^-] = [H_3O^+] + [Na^+]$$

The concentration of sodium ions is the same as the initial concentration of the NaOH, $[NaOH]_{initial}$, and so the material-balance relation is $[Na^+] = [NaOH]_{initial}$. It follows that

$$[OH^-] = [H_3O^+] + [NaOH]_{initial}$$

The autoprotolysis constant now becomes

$$K_w = [H_3O^+]([H_3O^+] + [NaOH]_{initial}) \qquad (17)$$

The concentration of hydronium ions can be obtained by solving this equation with the quadratic formula.

EXAMPLE 11.14 **Calculating the pH of a very dilute aqueous solution of a strong acid**

What is the pH of 8.0×10^{-8} M HCl(aq)?

Anticipate Although the acid is very dilute, it is an acid, and we should expect a pH of slightly less than 7.

PLAN Let $[HCl]_{initial} = 8.0 \times 10^{-8}\ mol{\cdot}L^{-1}$ and $[H_3O^+] = x$; substitute them in Eq. 16.

SOLVE

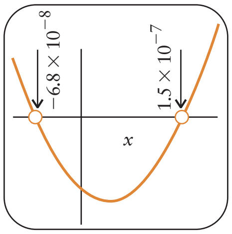
From $[H_3O^+]^2 - [HCl]_{initial}[H_3O^+] - K_w = 0$,

$$x^2 - (8.0 \times 10^{-8})x - (1.0 \times 10^{-14}) = 0$$

From the quadratic formula,

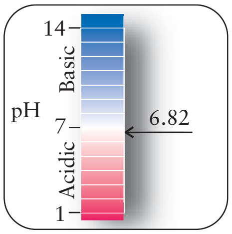
$$x = \frac{(8.0 \times 10^{-8}) \pm \sqrt{(-8.0 \times 10^{-8})^2 - 4(1)(-1.0 \times 10^{-14})}}{2(1)}$$

$$= 1.5 \times 10^{-7} \text{ or } -6.8 \times 10^{-8}$$



Reject the negative root and use $pH = -\log x$.

$$pH = -\log(1.5 \times 10^{-7}) = 6.82$$



Evaluate As expected, the pH is slightly less than 7.

Self-Test 11.18A What is the pH of 1.0×10^{-7} M $HNO_3(aq)$?

[***Answer:*** 6.79]

Self-Test 11.18B What is the pH of 2.0×10^{-7} M NaOH(aq)?

In very dilute solutions of strong acids and bases, the pH is significantly affected by the autoprotolysis of water. The pH is determined by solving three simultaneous equations: the charge-balance equation, the material-balance equation, and the expression for K_w.

11.19 Very Dilute Solutions of Weak Acids

Autoprotolysis also contributes to the pH of very dilute solutions of weak acids. In fact, some acids, such as hypoiodous acid, HIO, are so weak and undergo so little deprotonation that to find the pH of these solutions, we must always take into account the autoprotolysis of water.

HOW DO WE DO THAT?

The calculation of pH for very dilute solutions of a weak acid HA is similar to that for strong acids in Section 11.18. It is based on the fact that, apart from water, there are four species in solution—namely, HA, A^-, H_3O^+, and OH^-. Because there are four unknowns, we need four equations to find their concentrations. Two relations that we can use are the autoprotolysis constant of water and the acidity constant of the acid HA:

$$K_w = [H_3O^+][OH^-] \qquad K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

Charge balance provides a third equation:

$$[H_3O^+] = [OH^-] + [A^-]$$

Material balance provides the fourth equation: the total concentration of A groups (for instance, F atoms if the acid added is HF) must be equal to the initial concentration of the acid:

$$[HA]_{initial} = [HA] + [A^-]$$

To find an expression for the concentration of hydronium ions in terms of the initial concentration of the acid, we rearrange the charge-balance relation to express the concentration of A^- in terms of $[H_3O^+]$:

$$[A^-] = [H_3O^+] - [OH^-]$$

Then we express $[OH^-]$ in terms of the hydronium ion concentration by using the autoprotolysis expression:

$$[A^-] = [H_3O^+] - \frac{K_w}{[H_3O^+]}$$

When we substitute this expression into the material-balance equation, we obtain

$$[HA] = [HA]_{initial} - [A^-] = [HA]_{initial} - \left([H_3O^+] - \frac{K_w}{[H_3O^+]}\right)$$

$$= [HA]_{initial} - [H_3O^+] + \frac{K_w}{[H_3O^+]}$$

Now we substitute these expressions for [HA] and $[A^-]$ into K_a to obtain

$$K_a = \frac{[H_3O^+]\left([H_3O^+] - \dfrac{K_w}{[H_3O^+]}\right)}{[HA]_{initial} - [H_3O^+] + \dfrac{K_w}{[H_3O^+]}}$$

The expression we just derived is certainly intimidating, but many experimental conditions allow it to be simplified. For example, in many solutions of weak acids, $[H_3O^+] > 10^{-6}$ (that is, pH < 6). Under these conditions, $K_w/[H_3O^+] < 10^{-8}$ and we can ignore this term in both the numerator and the denominator:

Remember that $[H_3O^+]$ is really $[H_3O^+]/c°$.

$$K_a = \frac{[H_3O^+]^2}{[HA]_{initial} - [H_3O^+]} \tag{18a}$$

However, when the acid is so dilute or so weak that $[H_3O^+] \leq 10^{-6}$ (that is, when the pH lies between 6 and 7), then we must solve the full expression for K_a, which can be rearranged into

$$[H_3O^+]^3 + K_a[H_3O^+]^2 - (K_w + K_a[HA]_{initial})[H_3O^+] - K_aK_w = 0 \tag{18b}$$

This is a cubic equation in $[H_3O^+]$. To solve this equation, it is best to use a graphing calculator or mathematical software like that on the Web site for this text.

EXAMPLE 11.15 **Estimating the pH of a dilute aqueous solution of a weak acid when the autoprotolysis of water must be considered.**

Use Eq. 18b to estimate the pH of a 1.0×10^{-4} M aqueous phenol solution.

Anticipate Phenol, C_6H_5OH, is a weak acid, so expect pH < 7; but the pH will be only slightly less than 7 because the solution is so dilute.

PLAN Because Eq. 18b is complicated, first find the numerical factor of the third term and the numerical value of the fourth term. For simplicity, write $x = [H_3O^+]$.

SOLVE

Find K_a for phenol in Table 11.1.

$$K_a = 1.3 \times 10^{-10}$$

Evaluate $K_w + K_a[HA]_{initial}$.

$$K_w + K_a[HA]_{initial} = 1.0 \times 10^{-14} + (1.3 \times 10^{-10}) \times (1.0 \times 10^{-4}) = 2.3 \times 10^{-14}$$

Evaluate K_aK_w.

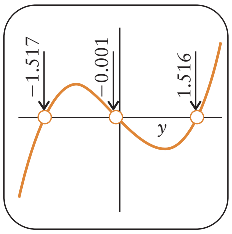
$$K_aK_w = (1.3 \times 10^{-10}) \times (1.0 \times 10^{-14}) = 1.3 \times 10^{-24}$$

Substitute the values into Eq. 18b with $[H_3O^+] = x$,

$$x^3 + (1.3 \times 10^{-10})x^2 - (2.3 \times 10^{-14})x - (1.3 \times 10^{-24}) = 0$$

To simplify the coefficients, write $x = y \times 10^{-7}$ and divide the resulting equation through by 10^{-21}.

$$y^3 + 0.0013y^2 - 2.3y - 0.0013 = 0$$

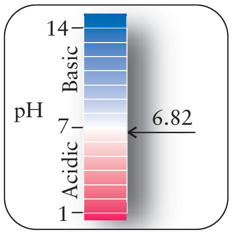


Find the positive root.

The only positive root is $y = 1.516$; so $x = 1.5 \times 10^{-7}$

From $\text{pH} = -\log[H_3O^+]$ and $[H_3O^+] = x$,

$$\text{pH} = -\log(1.5 \times 10^{-7}) = 6.82$$



Evaluate As expected, the pH is slightly less than 7.

Self-Test 11.19A Use Eq. 18b and the information in Table 11.1 to estimate the pH of 2.0×10^{-4} M HCN(aq).

[*Answer:* 6.48]

Self-Test 11.19B Use Eq. 18b and the information in Table 11.1 to estimate the pH of 1.0×10^{-2} M HIO(aq).

In aqueous solutions of very weak acids, the autoprotolysis of water must be taken into account if the hydronium ion concentration is less than 10^{-6} mol·L^{-1}. The expressions for K_w and K_a are combined with the equations for charge balance and material balance to find the pH.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Write the formulas for conjugate acids and bases (Example 11.1).

❑ 2 Identify Brønsted and Lewis acids and bases in a chemical reaction (Self-Test 11.2).

❑ 3 Calculate the concentrations of ions in a solution of a strong acid or base (Example 11.2).

❑ 4 Calculate the pH and pOH of a solution of a strong acid or base (Example 11.3 and Section 11.6).

❑ 5 Calculate the H_3O^+ concentration in a solution from its pH (Example 11.4).

❑ 6 Show how the K_a and pK_a of an acid are related to the K_b and pK_b of its conjugate base (Section 11.8).

❑ 7 Use K_a values to predict the relative strengths of two acids or two bases (Example 11.5).

❑ 8 Predict the relative strengths of acids from molecular structures (Example 11.6).

❑ 9 Calculate the pH and percentage deprotonation of a weak acid (Toolbox 11.1 and Example 11.7).

❑ 10 Calculate the value of K_a for a weak acid (Example 11.8).

❑ 11 Calculate the pH and percentage protonation of a weak base (Toolbox 11.2 and Example 11.9).

❑ 12 Calculate the pH of an electrolyte solution (Examples 11.10 and 11.11).

❑ 13 Calculate the pH of a solution of a polyprotic acid (Section 11.14 and Example 11.13).

❑ 14 Estimate the pH of a solution of an amphiprotic salt (Example 11.12).

❑ 15 Calculate the concentrations of all species in a polyprotic acid solution (Toolbox 11.3 and Example 11.13).

❑ 16 Find the pH of an aqueous solution of strong acid or base that is so dilute that the autoprotolysis of water significantly affects the pH (Example 11.14).

❑ 17 Find the pH of an aqueous solution of a weak acid for which the autoprotolysis of water significantly affects the pH (Example 11.15).

EXERCISES

Proton Transfer Reactions

11.1 Write the formulas for the conjugate acids of (a) CH_3NH_2, methylamine; (b) NH_2NH_2, hydrazine; (c) HCO_3^-; and the conjugate bases of (d) HCO_3^-; (e) C_6H_5OH, phenol; (f) CH_3COOH.

11.2 Write the formulas for the conjugate acids of (a) $C_2O_4^{2-}$, the oxalate ion; (b) $C_6H_5NH_2$, aniline; (c) NH_2OH, hydroxylamine; and the conjugate bases of (d) H_2O_2, hydrogen peroxide; (e) HNO_2; (f) $HCrO_4^-$.

11.3 Write the proton transfer equilibria for the following acids in aqueous solution and identify the conjugate acid–base pairs in each one: (a) H_2SO_4; (b) $C_6H_5NH_3^+$, anilinium ion; (c) $H_2PO_4^-$; (d) HCOOH, formic acid; (e) $NH_2NH_3^+$, hydrazinium ion.

11.4 Write the proton transfer equilibria for the following bases in aqueous solution and identify the conjugate acid–base pairs in each one: (a) CN^-; (b) NH_2NH_2, hydrazine; (c) CO_3^{2-}; (d) HPO_4^{2-}; (e) $CO(NH_2)_2$, urea.

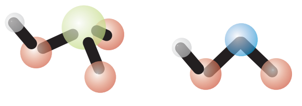
11.5 Identify (a) the Brønsted acid and base in the following reaction, and (b) the conjugate base and acid formed:

$$HNO_3(aq) + HPO_4^{2-}(aq) \rightleftharpoons NO_3^-(aq) + H_2PO_4^-(aq)$$

11.6 Identify (a) the Brønsted acid and base in the following reaction, and (b) the conjugate base and acid formed:

$$HSO_3^-(aq) + CH_3NH_3^+(aq) \rightleftharpoons H_2SO_3(aq) + CH_3NH_2(aq)$$

11.7 Below are the molecular models of two oxoacids. Write the name of each acid and then draw the model of its conjugate base. (Red = O, light gray = H, green = Cl, and blue = N.)



(a) (b)

11.8 Below are the molecular models of two oxoacids. Write the name of each acid and then draw the model of its conjugate base. (Red = O, light gray = H, green = Cl, and blue = N.)

(a) (b)

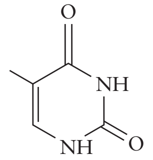
11.9 Which of the following reactions can be classified as reactions between Brønsted acids and bases? For those that can be so classified, identify the acid and the base. (*Hint:* It may help to write the net ionic equations.)
(a) $NH_4I(aq) + H_2O(l) \longrightarrow NH_3(aq) + H_3O^+(aq) + I^-(aq)$
(b) $NH_4I(s) \xrightarrow{\Delta} NH_3(g) + HI(g)$
(c) $CH_3COOH(aq) + NH_3(aq) \longrightarrow CH_3CONH_2(aq) + H_2O(l)$
(d) $NH_4I(am) + KNH_2(am) \longrightarrow KI(am) + 2\ NH_3(l)$ (Note: "am" indicates that liquid ammonia is the solvent.)

11.10 Which of the following reactions can be classified as reactions between Brønsted acids and bases? For those that can be so classified, identify the acid and the base. (*Hint:* It may help to write the net ionic equations.)
(a) $KOH(aq) + CH_3I(aq) \longrightarrow CH_3OH(aq) + KI(aq)$
(b) $AgNO_3(aq) + HCl(aq) \longrightarrow AgCl(s) + HNO_3(aq)$
(c) $2\ NaHCO_3(am) + 2\ NH_3(l) \longrightarrow Na_2CO_3(s) + (NH_4)_2CO_3(am)$ (Note: "am" indicates that liquid ammonia is the solvent.)
(d) $H_2S(aq) + Na_2S(s) \longrightarrow 2\ NaHS(aq)$

11.11 Write the two proton transfer equilibria that demonstrate the amphiprotic character of (a) HCO_3^-; (b) HPO_4^{2-}. Identify the conjugate acid–base pairs in each equilibrium.

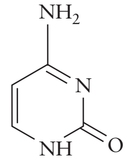
11.12 Write the two proton transfer equilibria that show the amphiprotic character of (a) $H_2PO_3^-$; (b) NH_3. Identify the conjugate acid–base pairs in each equilibrium.

11.13 The two strands of the nucleic acid DNA are held together by four organic bases. The structure of one of these bases, thymine, is shown below. (a) How many protons can this base accept? (b) Draw the structure of each conjugate acid that can be formed. (c) Mark with an asterisk any structure that can show amphiprotic behavior in aqueous solution.



Thymine

11.14 The two strands of the nucleic acid DNA are held together by four organic bases. The structure of one of these bases, cytosine, is shown below. (a) How many protons can this base accept? (b) Draw the structure of each conjugate acid that can be formed. (c) Mark with an asterisk any structure that can show amphiprotic behavior in aqueous solution.



Cytosine

Lewis Acids and Bases

11.15 Draw the Lewis structure for each of the following species and identify each as a Lewis acid or Lewis base: (a) NH_3; (b) BF_3; (c) Ag^+; (d) F^-; (e) H^-.

11.16 Draw the Lewis structure for each of the following species and identify each as a Lewis acid or Lewis base: (a) H^+; (b) Al^{3+}; (c) CN^-; (d) NO_2^-; (e) CH_3O^- (the C atom is the central atom).

11.17 Write the Lewis structure of each reactant, identify the Lewis acid and the Lewis base, and then write the Lewis structure of the product (a complex) for the following Lewis acid–base reactions:
(a) $PF_5 + F^- \longrightarrow$
(b) $Cl^- + SO_2 \longrightarrow$

11.18 Write the Lewis structure of each reactant, identify the Lewis acid and the Lewis base, and then write the Lewis structure of the product (a complex) for the following Lewis acid–base reactions:
(a) $F^- + BrF_3 \longrightarrow$
(b) $FeCl_3 + Cl^- \longrightarrow$

11.19 State whether the following oxides are acidic, basic, or amphoteric: (a) BaO; (b) SO_3; (c) As_2O_3; (d) Bi_2O_3.

11.20 State whether the following oxides are acidic, basic, or amphoteric: (a) SO_2; (b) CaO; (c) P_4O_{10}; (d) TeO_2.

Strong Acids and Bases

11.21 The concentration of HCl in hydrochloric acid is reduced to 12% of its initial value by dilution. What is the difference in the pH values of the two solutions?

11.22 The concentration of $Ca(OH)_2$ in an aqueous solution is reduced to 5.2% of its initial value by dilution. What is the difference in the pH values of the two solutions?

11.23 Calculate the molarity of OH^- in solutions with the following concentrations of H_3O^+: (a) 0.020 $mol{\cdot}L^{-1}$; (b) 1.0×10^{-5} $mol{\cdot}L^{-1}$; (c) 3.1 $mmol{\cdot}L^{-1}$.

11.24 Estimate the molarity of H_3O^+ in solutions with the following concentrations of OH^-: (a) 0.024 $mol{\cdot}L^{-1}$; (b) 4.5×10^{-5} $mol{\cdot}L^{-1}$; (c) 1.60 $mmol{\cdot}L^{-1}$.

11.25 The value of K_w for water at body temperature (37°C) is 2.1×10^{-14}. (a) What is the molarity of H_3O^+ ions and the pH of neutral water at 37°C? (b) What is the molarity of OH^- in neutral water at 37°C?

11.26 The concentration of H_3O^+ ions at the freezing point of water is 3.9×10^{-8} $mol{\cdot}L^{-1}$. (a) Calculate K_w and pK_w at 0.0°C. (b) What is the pH of neutral water at 0.0°C?

11.27 Calculate the initial molarity of $Ba(OH)_2$ and the molarities of Ba^{2+}, OH^-, and H_3O^+ in an aqueous solution that contains 0.43 g of $Ba(OH)_2$ in 0.100 L of solution.

11.28 Calculate the initial molarity of KNH_2 and the molarities of K^+, NH_2^-, OH^-, and H_3O^+ in an aqueous solution that contains 0.60 g of KNH_2 in 0.250 L of solution.

11.29 A careless laboratory technician wants to prepare 200.0 mL of a 0.025 M HCl(aq) solution, but uses a 250.0-mL volumetric flask by mistake. (a) What would the pH of the desired solution have been? (b) What will be the actual pH of the solution as prepared?

11.30 A careless laboratory technician prepares 300.0 mL of 0.0175 M KOH(aq) and pipets 25.0 mL of the solution into a beaker. The beaker is allowed to stand in a warm place for two days before use, during which time some of the water evaporates and the volume is reduced to 18.0 mL. (a) What would the pH of the solution as initially prepared have been? (b) What will be the actual pH of the solution after the evaporation?

11.31 The pH of several solutions was measured in the research laboratories of a food company; convert each of the following pH values into the molarity of H_3O^+ ions: (a) 3.3 (the pH of sour

orange juice); (b) 6.7 (the pH of a saliva sample); (c) 4.4 (the pH of beer); (d) 5.3 (the pH of a coffee sample).

11.32 The pH of several solutions was measured in a hospital laboratory; convert each of the following pH values into the molarity of H_3O^+ ions: (a) 4.8 (the pH of a urine sample); (b) 0.7 (the pH of a sample of fluid extracted from a stomach); (c) 7.4 (the pH of blood); (d) 8.1 (the pH of exocrine pancreatic secretions).

11.33 Calculate the pH and pOH of each of the following aqueous solutions of strong acid or base: (a) 0.0146 M HNO_3(aq); (b) 0.11 M HCl(aq); (c) 0.0092 M $Ba(OH)_2$(aq); (d) 2.00 mL of 0.175 M KOH(aq) after dilution to 0.500 L; (e) 13.6 mg of NaOH dissolved in 0.350 L of solution; (f) 75.0 mL of 3.5×10^{-4} M HBr(aq) after dilution to 0.500 L.

11.34 Calculate the pH and pOH of each of the following aqueous solutions of strong acid or base: (a) 0.0356 M HI(aq); (b) 0.0725 M HCl(aq); (c) 3.46×10^{-3} M $Ba(OH)_2$(aq); (d) 10.9 mg of KOH dissolved in 10.0 mL of solution; (e) 10.0 mL of 5.00 M NaOH(aq) after dilution to 2.50 L; (f) 5.0 mL of 3.5×10^{-4} M $HClO_4$(aq) after dilution to 25.0 mL.

11.35 A student added solid Na_2O to a 200.0-mL volumetric flask, which was then filled with water, resulting in 200.0 mL of NaOH solution. 5.00 mL of the solution was then transferred to another volumetric flask and diluted to 500.0 mL. The pH of the diluted solution is 13.25. What is the concentration of hydroxide ion in (a) the diluted solution? (b) the original solution? (c) What mass of Na_2O was added to the first flask?

11.36 A student added solid K_2O to a 500.0 mL volumetric flask, which was then filled with water, resulting in 500.0 mL of KOH solution. 10.0 mL of the solution was then transferred to another volumetric flask and diluted to 300.0 mL. The pH of the diluted solution is 14.12. What is the concentration of hydroxide ion in (a) the diluted solution? (b) the original solution? (c) What mass of K_2O was added to the first flask?

Weak Acids and Bases

11.37 Give the K_a value of each of the following acids: (a) phosphoric acid, H_3PO_4, $pK_{a1} = 2.12$; (b) phosphorous acid, H_3PO_3, $pK_{a1} = 2.00$; (c) selenous acid, H_2SeO_3, $pK_{a1} = 2.46$; (d) hydrogen selenate ion, $HSeO_4^-$, $pK_{a2} = 1.92$. (e) List the acids in order of increasing strength.

11.38 Give the pK_b values of the following bases: (a) ammonia, NH_3, $K_b = 1.8 \times 10^{-5}$; (b) deuterated ammonia, ND_3, $K_b = 1.1 \times 10^{-5}$; (c) hydrazine, NH_2NH_2, $K_b = 1.7 \times 10^{-6}$; (d) hydroxylamine, NH_2OH, $K_b = 1.1 \times 10^{-8}$. (e) List the bases in order of increasing strength.

11.39 For each of the following weak acids, write the proton transfer equilibrium equation and the expression for the equilibrium constant K_a. Identify the conjugate base, write the appropriate proton transfer equation, and write the expression for the basicity constant K_b. (a) $HClO_2$; (b) HCN; (c) C_6H_5OH.

11.40 For each of the following weak bases, write the proton transfer equilibrium equation and the expression for the equilibrium constant K_b. Identify the conjugate acid, write the appropriate proton transfer equation, and write the expression for the acidity constant K_a. (a) $(CH_3)_2NH$, dimethylamine; (b) $C_{14}H_{10}N_2$, nicotine; (c) $C_6H_5NH_2$, aniline.

11.41 Using data available in Tables 11.1 and 11.2, place the following acids in order of increasing strength: HNO_2, $HClO_2$, $^+NH_3OH$, $(CH_3)_2NH_2^+$.

11.42 Using data available in Tables 11.1 and 11.2, place the following acids in order of increasing strength: HCOOH, $(CH_3)_3NH^+$, $N_2H_5^+$, HF.

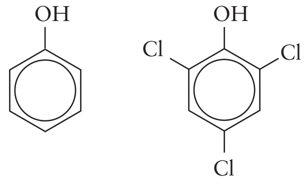
11.43 Using data in Tables 11.1 and 11.2, place the following bases in order of increasing strength: F^-, NH_3, $CH_3CO_2^-$, C_5H_5N (pyridine).

11.44 Using data in Tables 11.1 and 11.2, place the following bases in order of increasing strength: CN^-, $(C_2H_5)_3N$, N_2H_4 (hydrazine), BrO^-.

11.45 Label each of the following species as a strong or weak acid. Refer to Tables 11.1, 11.2, and 11.3. (a) $HClO_3$; (b) H_2S; (c) HSO_4^-; (d) $CH_3NH_3^+$; (e) HCO_3^-; (f) HNO_3; (g) CH_4.

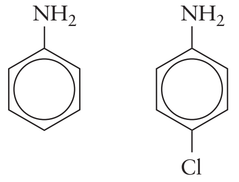
11.46 Label each of the following species as a strong or weak base. Refer to Tables 11.1, 11.2, and 11.3. (a) O^{2-}; (b) Br^-; (c) HSO_4^-; (d) HCO_3^-; (e) CH_3NH_2; (f) H_2; (g) CH_3^-.

11.47 The values of K_a for phenol and 2,4,6-trichlorophenol (see following structures) are 1.3×10^{-10} and 1.0×10^{-6}, respectively. Which is the stronger acid? Account for the difference in acid strength.



Phenol 2,4,6-Trichlorophenol

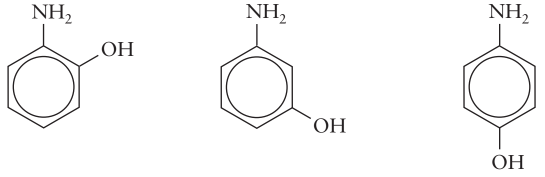
11.48 The value of pK_b for aniline is 9.37 and that for 4-chloroaniline is 9.85 (see the following structures). Which is the stronger base? Account for the difference in base strength.



Aniline 4-Chloroaniline

11.49 Arrange the following bases in order of increasing strength on the basis of the pK_a values of their conjugate acids, which are given in parentheses: (a) ammonia (9.26); (b) methylamine (10.56); (c) ethylamine (10.81); (d) aniline (4.63) (see Exercise 11.48). Is there a simple pattern of strengths?

11.50 Arrange the following bases in order of increasing strength on the basis of the pK_a values of their conjugate acids, which are given in parentheses: (a) aniline (4.63) (see Exercise 11.48); (b) 2-hydroxyaniline (4.72); (c) 3-hydroxyaniline (4.17); (d) 4-hydroxyaniline (5.47). Is there a simple pattern of strengths?



2-Hydroxyaniline 3-Hydroxyaniline 4-Hydroxyaniline

11.51 The pK_a of HIO(aq), hypoiodous acid, is 10.64 and that of HIO_3(aq), iodic acid, is 0.77. Account for the difference in acid strength.

11.52 The pK_a of HClO(aq), hypochlorous acid, is 7.53 and that of HBrO(aq), hypobromous acid, is 8.69. Account for the difference in acid strength.

11.53 Determine which acid in each of the following pairs is stronger and explain why: (a) HF or HCl; (b) HClO or $HClO_2$; (c) $HBrO_2$ or $HClO_2$; (d) $HClO_4$ or H_3PO_4; (e) HNO_3 or HNO_2; (f) H_2CO_3 or H_2GeO_3.

11.54 Determine which acid in each of the following pairs is stronger and explain why: (a) H_3AsO_4 or H_3PO_4; (b) $HBrO_3$ or HBrO; (c) H_3PO_4 or H_3PO_3; (d) H_2Te or H_2Se; (e) H_2S or HCl; (f) HClO or HIO.

11.55 Suggest an explanation for the different strengths of (a) acetic acid and trichloroacetic acid; (b) acetic acid and formic acid.

11.56 Suggest an explanation for the different strengths of (a) ammonia and methylamine; (b) hydrazine and hydroxylamine.

The pH of Solutions of Weak Acids and Bases

Refer to Tables 11.1 and 11.2 for the appropriate K_a and K_b values for the following exercises.

11.57 Calculate the pH, pOH, and percentage deprotonation of each of the following aqueous solutions: (a) 0.20 M CH_3COOH(aq); (b) 0.20 M CCl_3COOH(aq); (c) 0.20 M HCOOH(aq). (d) Explain any differences in pH on the basis of molecular structure.

11.58 Lactic acid is produced by muscles during exercise. Calculate the pH, pOH, and percentage deprotonation of each of the following aqueous solutions of lactic acid, $CH_3CH(OH)COOH$: (a) 0.15 M; (b) 1.5×10^{-3} M; (c) 1.5×10^{-5} M.

11.59 (a) When the pH of 0.10 M $HClO_2$(aq) was measured, it was found to be 1.2. What are the values of K_a and pK_a of chlorous acid? (b) The pH of a 0.10 M propylamine, $C_3H_7NH_2$, aqueous solution was measured as 11.86. What are the values of K_b and pK_b of propylamine?

11.60 (a) The pH of 0.015 M HNO_2(aq) was measured as 2.63. What are the values of K_a and pK_a of nitrous acid? (b) The pH of 0.10 M $C_4H_9NH_2$(aq), butylamine, was measured as 12.04. What are the values of K_b and pK_b of butylamine?

11.61 Calculate the pH, pOH, and percentage protonation of solute in each of the following aqueous solutions: (a) 0.057 M NH_3(aq); (b) 0.162 M NH_2OH(aq); (c) 0.35 M $(CH_3)_3N$(aq); (d) 0.0073 M codeine, given that the pK_a of its conjugate acid is 8.21.

11.62 Calculate the pOH, pH, and percentage protonation of solute in each of the following aqueous solutions: (a) 0.082 M C_5H_5N(aq), pyridine; (b) 0.0103 M $C_{10}H_{14}N_2$(aq), nicotine; (c) 0.060 M quinine, given that the pK_a of its conjugate acid is 8.52; (d) 0.045 M strychnine, given that the K_a of its conjugate acid is 5.49×10^{-9}.

11.63 Find the initial concentration of the weak acid or base in each of the following aqueous solutions: (a) a solution of HClO with pH = 4.60; (b) a solution of hydrazine, NH_2NH_2, with pH = 10.20.

11.64 Find the initial concentration of the weak acid or base in each of the following aqueous solutions: (a) a solution of HClO with pH = 5.1; (b) a solution of pyridine, C_5H_5N, with pH = 9.1.

11.65 The percentage deprotonation of benzoic acid in a 0.110 M solution is 2.4%. What is the pH of the solution and the K_a of benzoic acid?

11.66 The percentage deprotonation of veronal (diethylbarbituric acid) in a 0.020 M aqueous solution is 0.14%. What is the pH of the solution and what is the K_a of veronal?

11.67 The percentage protonation of octylamine (an organic base) in a 0.100 M aqueous solution is 6.7%. What is the pH of the solution and what is the K_b of octylamine?

11.68 An aqueous solution is 35.0% by mass methylamine (CH_3NH_2) and has a density of 0.85 $g{\cdot}cm^{-3}$. (a) Draw the Lewis structures of a methylamine molecule and its conjugate acid. (b) If 50.0 mL of this solution is diluted to 1000.0 mL, what is the pH of the resulting solution?

11.69 Write the equilibrium constant for the following reaction and calculate the value of K at 298 K for the reaction $HNO_2(aq) + NH_3(aq) \rightleftharpoons NH_4^+(aq) + NO_2^-(aq)$ using the data in Tables 11.1 and 11.2.

11.70 Write the equilibrium constant for the reaction $HIO_3(aq) + NH_2NH_2(aq) \rightleftharpoons NH_2NH_3^+(aq) + IO_3^-(aq)$ and calculate the value of K at 298 K using the data in Tables 11.1 and 11.2.

11.71 Determine whether an aqueous solution of each of the following salts has a pH equal to, greater than, or less than 7. If pH > 7 or pH < 7, write a chemical equation to justify your answer. (a) NH_4Br; (b) Na_2CO_3; (c) KF; (d) KBr; (e) $AlCl_3$; (f) $Cu(NO_3)_2$.

11.72 Determine whether an aqueous solution of each of the following salts has a pH equal to, greater than, or less than 7. If pH > 7 or pH < 7, write a chemical equation to justify your answer. (a) $K_2C_2O_4$, potassium oxalate; (b) $Ca(NO_3)_2$; (c) CH_3NH_3Cl, methylamine hydrochloride; (d) K_3PO_4; (e) $FeCl_3$; (f) C_5H_5NHCl, pyridinium chloride.

11.73 Rank the following solutions in order of increasing pH: (a) 1.0×10^{-5} M HCl(aq); (b) 0.20 M CH_3NH_3Cl(aq); (c) 0.20 M CH_3COOH(aq); (d) 0.20 M $C_6H_5NH_2$(aq). Justify your ranking.

11.74 Rank the following solutions in order of increasing pH: (a) 1.0×10^{-5} M NaOH(aq); (b) 0.20 M $NaNO_2$(aq); (c) 0.20 M NH_3(aq); (d) 0.20 M NaCN(aq). Justify your ranking.

11.75 Calculate the pH of each of the following solutions: (a) 0.63 M $NaCH_3CO_2$(aq); (b) 0.19 M NH_4Cl(aq); (c) 0.055 M $AlCl_3$(aq); (d) 0.65 M KCN(aq).

11.76 Calculate the pH of each of the following solutions: (a) 0.25 M CH_3NH_3Cl(aq); (b) 0.13 M Na_2SO_3(aq); (c) 0.071 M $FeCl_3$(aq).

11.77 A 15.5-g sample of CH_3NH_3Cl is dissolved in water to make 450. mL of solution. What is the pH of the solution?

11.78 A 7.8-g sample of $C_6H_5NH_3Cl$ is dissolved in water to make 350. mL of solution. Determine the percentage deprotonation of the cation.

11.79 During the analysis of an unknown acid HA, a 0.010 M solution of the sodium salt of the acid was found to have a pH of 10.35. Use Table 11.1 to write the formula of the acid.

11.80 During the analysis of an unknown weak base B, a 0.10 M solution of the nitrate salt of the base was found to have a pH of 3.13. Use Table 11.2 to write the formula of the base.

11.81 (a) A 150.-mL sample of 0.020 M $NaCH_3CO_2(aq)$ is diluted to 0.500 L. What is the concentration of acetic acid at equilibrium? (b) What is the pH of a solution resulting from the dissolution of 2.16 g of NH_4Br in water to form 0.400 L of solution?

11.82 (a) A 25.0-mL sample of 0.250 M KCN(aq) is diluted to 100.0 mL. What is the concentration of hydrocyanic acid at equilibrium? (b) A 1.59-g sample of $NaHCO_3$ is dissolved in water to form 200.0 mL of solution. What is the pH of the solution?

11.83 A 3.38-g sample of the sodium salt of alanine, $NaCH_3CH(NH_2)CO_2$, is dissolved in water, and then the solution is diluted to 50.0 mL. For alanine, $K_{a1} = 4.57 \times 10^{-3}$, $K_{a2} = 1.30 \times 10^{-10}$. What is the pH of the resulting solution?

11.84 The drug amphetamine, $C_6H_5CH_2CH(CH_3)NH_2$, $K_b = 7.8 \times 10^{-4}$, is usually marketed as the hydrogen bromide salt, $C_6H_5CH_2CH(CH_3)NH_3^+Br^-$, because it is much more stable in this solid form. Determine the pH of a solution made by dissolving 6.48 g of the salt to form 200.0 mL of solution.

Polyprotic Acids and Bases

Refer to Table 11.9 for the K_a values needed for the following exercises.

11.85 Calculate the pH of 0.15 M $H_2SO_4(aq)$ at 25°C.

11.86 Calculate the pH of 0.010 M $H_2SeO_4(aq)$, given that K_{a1} is very large and $K_{a2} = 1.2 \times 10^{-2}$.

11.87 Calculate the pH of each of the following diprotic acid solutions at 25°C, ignoring second deprotonations only when the approximation is justified: (a) 0.010 M $H_2CO_3(aq)$; (b) 0.10 M $(COOH)_2(aq)$; (c) 0.20 M $H_2S(aq)$.

11.88 Calculate the pH of each of the following diprotic acid solutions at 25°C, ignoring second deprotonations only when that approximation is justified: (a) 0.10 M $H_2S(aq)$; (b) 0.15 M $H_2C_4H_4O_6(aq)$, tartaric acid; (c) 1.1×10^{-3} M $H_2TeO_4(aq)$, telluric acid, for which $K_{a1} = 2.1 \times 10^{-8}$ and $K_{a2} = 6.5 \times 10^{-12}$.

11.89 Estimate the pH of (a) 0.15 M $NaHSO_3(aq)$; (b) 0.050 M $NaHSO_3(aq)$.

11.90 Estimate the pH of (a) 0.125 M $NaHCO_3(aq)$; (b) 0.250 M $KHCO_3(aq)$.

11.91 Citric acid, which is extracted from citrus fruits and pineapples, undergoes three successive deprotonations with pK_a values of 3.14, 5.95, and 6.39. Estimate the pH of (a) a 0.15 M aqueous solution of the monosodium salt; (b) a 0.075 M aqueous solution of the disodium salt.

11.92 Like sulfuric acid, a certain diprotic acid, H_2A, is a strong acid in its first deprotonation and a weak acid in its second deprotonation. A solution that is 0.020 M $H_2A(aq)$ has a pH of 1.66. What is the value of K_{a2} for this acid?

11.93 Calculate the concentrations of H_2CO_3, HCO_3^-, CO_3^{2-}, H_3O^+, and OH^- present in 0.0456 M $H_2CO_3(aq)$.

11.94 Calculate the concentrations of H_2SO_3, HSO_3^-, SO_3^{2-}, H_3O^+, and OH^- present in 0.125 M $H_2SO_3(aq)$.

11.95 Calculate the concentrations of H_2CO_3, HCO_3^-, CO_3^{2-}, H_3O^+, and OH^- present in 0.0456 M $Na_2CO_3(aq)$.

11.96 Calculate the concentrations of H_2SO_3, HSO_3^-, SO_3^{2-}, H_3O^+, and OH^- present in 0.125 M $Na_2SO_3(aq)$.

11.97 For each of the following polyprotic acids, state which species (H_2A, HA^-, or A^{2-}) you expect to be the form present in highest concentration in aqueous solution at pH = 6.50: (a) phosphorous acid; (b) oxalic acid; (c) hydrosulfuric acid.

11.98 For each of the following polyprotic acids, state which species (H_2A, HA^-, or A^{2-} of the diprotic acid or H_3A, H_2A^-, HA^{2-}, or A^{3-} for triprotic acids) you expect to be the form present in highest concentration in aqueous solution at pH = 5.0: (a) tartaric acid; (b) hydrosulfuric acid; (c) phosphoric acid.

11.99 A large volume of 0.150 M $H_2SO_3(aq)$ is treated with a solid, strong base to adjust the pH to 5.50. Assume that the addition of the base does not significantly affect the volume of the solution. Estimate the concentrations of H_2SO_3, HSO_3^-, and SO_3^{2-} present in the final solution.

11.100 A large volume of 0.250 M $H_2S(aq)$ is treated with a solid, strong base to adjust the pH to 9.35. Assume that the addition of the base does not significantly affect the volume of the solution. Estimate the concentrations of H_2S, HS^-, and S^{2-} present in the final solution.

11.101 Calculate the pH of each of the following acid solutions at 25°C; ignore second deprotonations only when that approximation is justified. (a) 1.0×10^{-4} M $H_3BO_3(aq)$, boric acid acts as a monoprotic acid; (b) 0.015 M $H_3PO_4(aq)$; (c) 0.10 M $H_2SO_3(aq)$.

11.102 Calculate the molarities of $(COOH)_2$, $HOOCCO_2^-$, $(CO_2)_2^{2-}$, H_3O^+, and OH^- in 0.12 M $(COOH)_2(aq)$.

11.103 Calculate the concentrations of all phosphate species in $H_3PO_4(aq)$ that has pH = 2.25, given that the total concentration of all four forms of the dissolved phosphates is 15 mmol·L^{-1}.

11.104 Ammonium acetate is prepared by the reaction of equal amounts of ammonium hydroxide and acetic acid. Determine the concentration of all solute species present in 0.100 M $NH_4CH_3CO_2(aq)$.

Autoprotolysis and pH

11.105 Calculate the pH of 6.55×10^{-7} M $HClO_4(aq)$.

11.106 Calculate the pH of 7.49×10^{-8} M HI(aq).

11.107 Calculate the pH of 9.78×10^{-8} M KOH(aq).

11.108 Calculate the pH of 8.23×10^{-7} M $NaNH_2(aq)$.

For Exercises 11.109 through 11.114, we suggest that you use a graphing calculator to solve the equation or suitable computer software to solve the set of simultaneous equations.

11.109 At what concentration is it necessary to take into account the autoprotolysis of water when calculating the pH of an aqueous acetic acid solution?

11.110 At what concentration is it necessary to take into account the autoprotolysis of water when calculating the pH of an aqueous chloroacetic acid solution? Account for any difference between this value and the answer to Exercise 10.109.

11.111 (a) Calculate the pH of 1.00×10^{-4} M and 1.00×10^{-6} M HBrO(aq), ignoring the effect of the autoprotolysis of water. (b) Repeat the calculations, taking into account the autoprotolysis of water.

11.112 (a) Calculate the pH of 2.50×10^{-4} M and 2.50×10^{-6} M phenol(aq), ignoring the effect of the autoprotolysis of water.

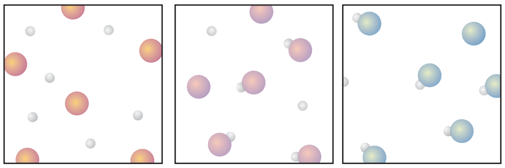
(b) Repeat the calculations, taking into account the autoprotolysis of water.

11.113 (a) Calculate the pH of 8.50×10^{-5} M and 7.37×10^{-6} M HCN(aq), ignoring the effect of the autoprotolysis of water.
(b) Repeat the calculations, taking into account the autoprotolysis of water.

11.114 (a) Calculate the pH of 1.89×10^{-5} M and 9.64×10^{-7} M HClO(aq), ignoring the effect of the autoprotolysis of water.
(b) Repeat the calculations, taking into account the autoprotolysis of water.

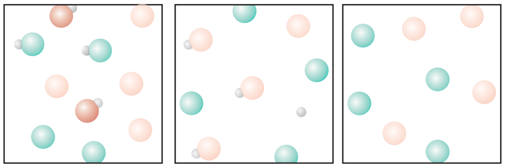
Integrated Exercises

11.115 The images below represent the solutes in the solutions of three acids (water molecules are not shown, hydrogen atoms and hydronium ions are represented by small gray spheres, conjugate bases by large colored spheres). (a) Which acid is a strong acid? (b) Which acid has the strongest conjugate base? (c) Which acid has the highest pK_a? Explain each of your answers.



(1) (2) (3)

11.116 The images below represent the solutes in the solutions of three salts (water molecules are not shown, hydrogen atoms and ions are represented by small gray spheres, hydroxide ions by red and gray spheres, cations by pink spheres and anions by green spheres). (a) Which salt has a cation that is the conjugate acid of a weak base? (b) Which salt has an anion that is the conjugate base of a weak acid? (c) Which salt has an anion that is the conjugate base of a strong acid? Explain each of your answers.



(1) (2) (3)

11.117 Hydronium and hydroxide ions appear to move through water much faster than other kinds of ions. Explain this observation.

11.118 Which of the following best describes the composition of a solution labeled "0.10 M H_2SO_4(aq)"?
(a) $[H_2SO_4] = 0.10$ M
(b) $[H_3O^+] > 0.10$ M, $[SO_4^{2-}] = 0.10$ M
(c) $[H_3O^+] = 0.20$ M, $[SO_4^{2-}] = 0.10$ M
(d) $[H_3O^+] > 0.10$ M, $[HSO_4^{2-}] < 0.10$ M
(e) $[H_3O^+] = 0.10$ M, $[HSO_4^{2-}] = 0.10$ M

11.119 A combustion analysis of 1.200 g of an anhydrous sodium salt gave 0.942 g of CO_2, 0.0964 g of H_2O, and 0.246 g of Na. The molar mass of the salt is 112.02 $g \cdot mol^{-1}$. (a) What is the chemical formula of the salt? (b) The salt contains carboxylate groups ($-CO_2^-$), and the carbon atoms are bonded together. Draw the Lewis structure of the anion. (c) Next, 1.50 g of this sodium salt was dissolved in water and diluted to 50.0 mL. Identify the dissolved substance: Is it an acid, a base, or is it amphiprotic? Calculate the pH of the solution.

11.120 Decide on the basis of the information in Table 11.3 whether carbonic acid is a strong or weak acid in liquid ammonia solvent. Explain your answer.

11.121 Draw the Lewis structure of boric acid, $B(OH)_3$. (a) Is resonance important for its description? (b) The proton transfer equilibrium for boric acid is given in a footnote to Table 11.1. In that reaction does boric acid act as a Lewis acid, a Lewis base, or neither? Justify your answer by using Lewis structures of boric acid and its conjugate base.

11.122 Dinitrogen monoxide, N_2O, reacts with water to form hyponitrous acid, $H_2N_2O_2$(aq), in a Lewis acid–base reaction. (a) Write the chemical equation for the reaction. (b) Draw the Lewis structures of N_2O and $H_2N_2O_2$ (the atoms are attached in the order HONNOH). (c) Identify the Lewis acid and Lewis base.

11.123 Acetic acid is used as a solvent for some reactions between acids and bases. (a) Nitrous acid and carbonic acids are both weak acids in water. Will either of them act as a strong acid in acetic acid? Explain your answer. (b) Will ammonia act as a strong or weak base in acetic acid? Explain your answer.

11.124 Sections 11.9 and 11.10 discuss the relationship between molecular structure and the strengths of acids. The same ideas can be applied to bases. (a) Explain the relative strengths of the Brønsted bases OH^-, NH_2^-, and CH_3^- (see Table 11.3). (b) Explain why NH_3 is a weak base in water, but PH_3 forms essentially neutral solutions. (c) If you were ranking the species in (a) or (b) as Lewis bases, would your rankings be the same or different? Explain your reasoning.

11.125 Use the thermodynamic data available in Appendix 2A to calculate the acidity constant of HF(aq).

11.126 The acidity of soil is determined by mixing a sample of soil with water and measuring the pH of the resulting slurry. Scientists have found that mixing the soil into 0.10 M $CaCl_2$(aq) instead of water provides more consistent results. Would you expect the pH of the slurry with $CaCl_2$ to differ from that measured using pure water? If so, how? If not, why not?

11.127 The autoprotolysis constant, K_{hw}, for heavy water at 25°C is 1.35×10^{-15}. (a) Write the chemical equation for the autoprotolysis (more precisely, the autodeuterolysis, because a deuteron is being transferred) of D_2O. (b) Evaluate pK_{hw} for D_2O at 25°C. (c) Calculate the molarities of D_3O^+ and OD^- in pure heavy water at 25°C. (d) Evaluate the pD and pOD of heavy water at 25°C. (e) Find the relation between pD, pOD, and pK_{hw}.

11.128 The pK_{hw} for the autoprotolysis of heavy water, D_2O, is 13.8330 at 30.°C. Assuming $\Delta H_r°$ for this reaction to be independent of temperature and using information from Exercise 11.127, calculate $\Delta S_r°$ for the autoprotolysis reaction. Suggest an interpretation of the sign. Suggest a reason why the autoprotolysis constant of heavy water differs from that of ordinary water.

11.129 Use Table 11.1 to determine the percentage deprotonation of 1.00 M aqueous lactic acid. At what temperature will the solution freeze? (Assume that the density of the solution is 1.00 $g \cdot cm^{-3}$.)

11.130 Is the osmotic pressure of 0.10 M H_2SO_4(aq) the same as, less than, or greater than that of 0.10 M HCl(aq)? Calculate the osmotic pressure of each solution to support your conclusion.

11.131 Estimate the enthalpy of deprotonation of formic acid at 25°C, given that $K_a = 1.765 \times 10^{-4}$ at 20°C and 1.768×10^{-4} at 30°C.

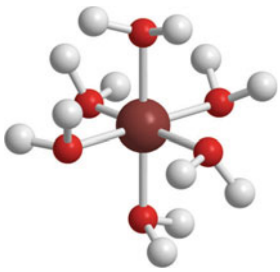
11.132 (a) The value of K_w at 40°C is 3.8×10^{-14}. What is the pH of pure water at 40°C? (b) Use data from part (a) and Exercise 11.25 and the values for the autoprotolysis of water at 25°C to determine graphically the enthalpy and entropy of the autoprotolysis of water. (c) Suggest an interpretation of the sign of $\Delta S°$. (d) Write an equation that describes the pH of pure water as a function of temperature.

11.133 The two acidity constants of oxalic acid, HOOCCOOH, differ by a factor of about 1000: $pK_{a1} = 1.23$ and $pK_{a2} = 4.19$. However, the two acidity constants of adipic acid, $HOOC(CH_2)_4COOH$, are close together: $pK_{a1} = 4.43$ and $pK_{a2} = 5.41$. Explain why the difference in acidity constants is so much greater for oxalic acid.

11.134 Although many chemical reactions take place in water, it is often necessary to use other solvents; liquid ammonia (normal boiling point, −33°C) has been used extensively. Many of the reactions that take place in water have analogous reactions in liquid ammonia. (a) Write the chemical equation for the autoprotolysis of NH_3. (b) What are the formulas of the acid and base species that result from the autoprotolysis of liquid ammonia? (c) The autoprotolysis constant, K_{am}, of liquid ammonia has the value 1×10^{-33} at −35°C. What is the value of pK_{am} at that temperature? (d) What is the molarity of NH_4^+ ions in liquid ammonia? (e) Evaluate pNH_4 and pNH_2, which are the analogs of pH and pOH, in liquid ammonia at −35°C.
(f) Determine the relation between pNH_4, pNH_2, and pK_{am}.

11.135 Recall from Section 10.13 that hemoglobin (Hb) molecules in blood carry O_2 molecules from the lungs, where the concentration of oxygen is high, to the tissues where it is low. In the tissues the equilibrium $H_3O^+(aq) + HbO_2^-(aq) \rightleftharpoons HHb(aq) + H_2O(l) + O_2(aq)$ releases oxygen. When muscles work hard, they produce lactic acid as a by-product. (a) What effect will the lactic acid have on the concentration of HbO_2^-? (b) When the hemoglobin returns to the lungs, where oxygen concentration is high, how does the concentration of HbO_2^- change?

11.136 The structures below show a hydrated d-metal ion. Draw the structure of the conjugate base of this complex.



Chemistry Connections

11.137 Rainwater is naturally slightly acidic due to the dissolved carbon dioxide. Acid rain results when acidic sulfur and nitrogen oxides produced during the combustion of coal and oil react with rainwater (see Box 11.1).
(a) The partial pressure of CO_2 in air saturated with water vapor at 25°C and 1.00 atm is 3.04×10^{-4} atm. Henry's constant for CO_2 in water is 2.3×10^{-2} mol·L^{-1}·atm^{-1}; and, for carbonic acid, $pK_{a1} = 6.37$. Assuming that all the dissolved CO_2 can be thought of as H_2CO_3, verify by calculation that the pH of "normal" rainwater is about 5.7.
(b) Scientists investigating acid rain measured the pH of a water sample from a lake and found it to be 4.8. The total concentration of dissolved carbonates in the lake is 4.50 mmol·L^{-1}. Determine the molar concentrations of the carbonate species CO_3^{2-}, HCO_3^-, and H_2CO_3 in the lake.
(c) Suppose that 1.00 tonne (1 t = 10^3 kg) of coal that is 2.5% sulfur by mass is burned in a coal-fired plant. What mass of SO_2 is produced?
(d) What is the pH of rainwater when the SO_2 generated in part (c) dissolves in a volume of water equivalent to 2.0 cm of rainfall over 2.6 km^2? (The pK_{a1} of sulfurous acid is 1.81. Consider the water to be initially pure and at a pH of 7.)
(e) If the SO_2 in part (c) is first oxidized to SO_3 before the rainfall, what would the pH of the same rainwater be?
(f) One process used to clean SO_2 from the emissions of coal-fired plants is to pass the stack gases along with air through a wet calcium carbonate slurry, where the following reaction takes place: $CaCO_3(s) + SO_2(g) + O_2(g) \longrightarrow CaSO_4(s) + CO_2(g)$. What mass of limestone ($CaCO_3$) is needed to remove 50.0 kg sulfur dioxide from stack gases if the removal process is 90% efficient?

AQUEOUS EQUILIBRIA

What Are the Key Ideas? The concentrations of dissolved ions satisfy the equilibrium constants for the reactions in which they participate.

Why Do We Need to Know This Material? The techniques described in this chapter provide the tools that we need to analyze and control the concentrations of ions in solution. Many reactions are carried out in solution, and so this material is fundamental to understanding chemistry. The ionic compounds released into waterways by individuals, industry, and agriculture can impair the quality of our water supplies. However, these hazardous ions can be identified and removed if we add the right reagents. Aqueous equilibria govern the stabilization of the pH in blood, seawater, and other solutions encountered in biology, medicine, and the environment.

What Do We Need to Know Already? This chapter develops the ideas in Chapters 10 and 11 and applies them to equilibria involving ions in aqueous solution. To prepare for the sections on titrations, review Section L. For the discussion of solubility equilibria, review Section I. The discussion of Lewis acids and bases in Section 12.13 is based on Section 11.2.

A primary goal of this chapter is to learn how to manage the pH of solutions of acids, bases, and their salts. The control of pH is crucial for the ability of organisms—including ourselves—to survive, because even minor drifts from the optimum value of the pH can cause enzymes to change their shape and cease to function. The information in this chapter is used in industry to control the pH of reaction mixtures and to purify water. In agriculture it is used to maintain the soil at an optimal pH. In the laboratory it is used to interpret the change in pH of a solution during a titration, one of the most common quantitative analytical techniques. It also forms the basis of **qualitative analysis,** the identification of the substances and ions present in a sample.

All these applications involve equilibria between species in solution, especially between species that can exchange protons. The common theme throughout this chapter is that all these equilibria can be treated in a similar way:

1. Identify the solute species present in the solution.
2. Identify the stoichiometric relations between the concentrations of solute species (often by setting up an equilibrium table).
3. Use those relations together with equilibrium constants to calculate the equilibrium concentrations of the solute species.

These three simple steps constitute a powerful and widely used technique. Initially we apply them to show how the pH of a solution can be kept nearly constant at a chosen value. Then we use them to show how to predict the pH of a solution at any stage of a titration. Next, we apply them to characterize equilibria between ions in solution. Finally, we consider how all these ideas can be combined to analyze the composition of aqueous solutions of ionic compounds.

MIXED SOLUTIONS AND BUFFERS

We have seen how to estimate the pH of a solution of a weak acid or base (Chapter 11), but suppose a salt of the acid or base is also present. How does that salt affect the pH of the solution? Suppose we have some dilute hydrochloric acid and add to it appreciable concentrations of the conjugate base of HCl, the Cl^- ion, as sodium chloride. Because HCl is a strong acid, its conjugate base is very weak and so has no measurable effect on pH. The pH of 0.10 M HCl(aq) is about 1.0, even after 0.10 mol NaCl has

been added to a liter of the solution. Now suppose instead that the solution contains acetic acid to which sodium acetate has been added (the acetate ion, $CH_3CO_2^-$, is the conjugate base of CH_3COOH). Because $CH_3CO_2^-$ is a base, we can predict that adding acetate ions (as sodium acetate) to a solution of acetic acid will increase the pH of the solution. Similarly, suppose we have a solution of ammonia and add ammonium chloride to it. The NH_4^+ ion acts as a weak acid in water; therefore, we can predict that adding ammonium ions (as ammonium chloride, for instance) to a solution of ammonia will lower the pH of the solution. As we shall see, such "mixed solutions"—solutions that contain a weak acid or a weak base and one of its salts—provide a means of stabilizing the pH of aqueous solutions such as blood plasma, seawater, detergents, sap, and reaction mixtures.

12.1 Buffer Action

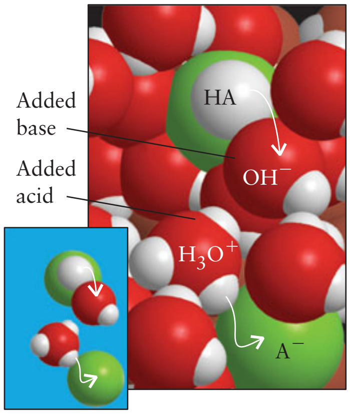

FIGURE 12.1 A solution can act as a buffer if it contains a weak acid, HA, which donates protons when a strong base is added, and the conjugate base, A^-, which accepts protons when a strong acid is added. In the inset, for clarity water molecules are represented by the blue background.

The most important type of mixed solution is a **buffer,** a solution in which the pH resists change when small amounts of strong acids or bases are added. Buffers are used to calibrate pH meters, to culture bacteria, and to control the pH of solutions in which chemical reactions are taking place. They are also administered intravenously to hospital patients. Human blood plasma is buffered to pH = 7.4; the ocean is buffered to about pH = 8.4 by a complex buffering process that depends on the presence of hydrogen carbonates and silicates. A buffer consists of an aqueous solution of a weak acid and its conjugate base supplied as a salt, or a weak base and its conjugate acid supplied as a salt. Examples are a solution of acetic acid and sodium acetate and a solution of ammonia and ammonium chloride.

When a drop of strong acid is added to pure water, the pH changes significantly. However, when the same amount is added to a buffer, the pH hardly changes at all. To understand why not, consider the dynamic equilibrium between a weak acid and its conjugate base in water:

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$

To prepare a buffer that makes use of this equilibrium, we need a solution that consists of similar amounts of acid (CH_3COOH) and its salt ($NaCH_3CO_2$). When a few drops of a strong acid are added to such a solution, the newly arrived H_3O^+ ions transfer protons to the $CH_3CO_2^-$ ions to form CH_3COOH and H_2O molecules (Fig. 12.1). Because the added H_3O^+ ions are removed by the $CH_3CO_2^-$ ions, the pH remains almost unchanged. In effect, the acetate ions act as a "sink" for protons. If a small amount of strong base is added instead, the incoming OH^- ions remove protons from the CH_3COOH molecules to produce $CH_3CO_2^-$ ions and H_2O molecules. In this case, the acetic acid molecules act as a source of protons. Because the added OH^- ions are removed by the CH_3COOH molecules, the concentration of OH^- ions remains nearly unchanged. Consequently, the H_3O^+ concentration (and the pH) is also left nearly unchanged.

Now consider the equilibrium

$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

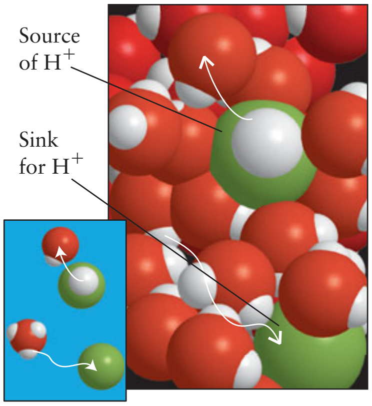

FIGURE 12.2 A buffer solution contains a weak base that acts as a sink for the protons supplied by a strong acid and a weak acid that acts as a source of protons to supply to a strong base being added. The joint action of the source and sink keeps the pH constant when strong acid or base is added. The inset highlights the buffer action by representing the water molecules as a blue background.

To prepare a buffer that makes use of this equilibrium, we prepare a solution that contains similar amounts of base (NH_3) and its salt (NH_4Cl). When a few drops of a solution of strong base are added to this solution, the incoming OH^- ions remove protons from NH_4^+ ions to form NH_3 and H_2O molecules. When instead a few drops of a strong acid are added, the incoming protons attach to NH_3 molecules to make NH_4^+ ions and hence are removed from the solution. In each case, the pH is left almost unchanged.

Thinking point: Could an aqueous solution of glycine, $^-O_2CCH_2NH_3^+$, which contains both acidic and basic groups, act as a buffer?

A buffer is a mixture of a weak conjugate acid–base pair that stabilizes the pH of a solution by providing both a source and a sink for protons (Fig. 12.2).

12.2 Designing a Buffer

Suppose we need to make up a buffer with a particular pH. For instance, we might be culturing bacteria and need to maintain a precise pH to sustain their metabolism. To choose the most appropriate buffer system, we need to know the value of the pH at which a given buffer stabilizes a solution. A mixture of a weak acid and its salt will act as a buffer at pH < 7 (the acidic side of neutrality) and is known as an **acid buffer.** A mixture of a weak base and its salt will act as a buffer at pH > 7 (the basic side of neutrality) and is known as a **basic buffer.** To find the precise pH at which a mixed solution of given composition will act as a buffer we carry out an equilibrium calculation very similar to those in Chapter 11, as shown in the following example.

EXAMPLE 12.1 Calculating the pH of a buffer solution

Suppose we are culturing bacteria that require an acid environment and want to prepare a buffer close to pH = 4. We prepare a buffer solution that is 0.040 M $NaCH_3CO_2$(aq) and 0.080 M CH_3COOH(aq) at 25°C. What is the pH of the solution?

Anticipate If the weak acid were present alone, we would expect pH < 7. Because some conjugate base is also present, we should expect the pH to be slightly higher than the acid-only value but still less than 7. In Example 11. 7 we calculated pH = 2.92 for the acid alone, so expect a pH higher than this value.

PLAN First, identify the weak acid and its conjugate base. Then, write the proton transfer equilibrium between them and rearrange the expression for K_a to give $[H_3O^+]$. Finally, calculate the pH.

What should we assume? That the extent of protonation of acetate ions and the deprotonation of acetic acid molecules is so small that the concentrations of both species are nearly the same as their initial values.

SOLVE The acid is CH_3COOH and its conjugate base is $CH_3CO_2^-$. The equilibrium to consider is

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$

From Table 11.1, $pK_a = 4.75$ and $K_a = 1.8 \times 10^{-5}$.

Find the equilibrium concentration of H_3O^+ ions from $K_a = [H_3O^+][CH_3CO_2^-]/[CH_3COOH]$.

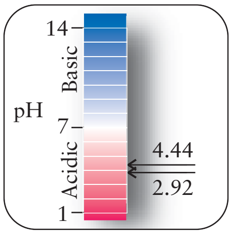
$$[H_3O^+] = K_a \times \frac{[CH_3COOH]}{[CH_3CO_2^-]}$$

Approximate the conjugate acid and base concentrations by their initial values.

$$[H_3O^+] \approx (1.8 \times 10^{-5}) \times \frac{0.080}{0.040}$$

From pH = –log $[H_3O^+]$,

$$\text{pH} \approx -\log\left\{(1.8 \times 10^{-5}) \times \frac{0.080}{0.040}\right\}$$
$$= 4.44$$



Evaluate As expected, the solution is less acidic than it would be if only the acid were present (pH = 2.92) and acts as an acid buffer at pH $\approx$ 4.

Self-Test 12.1A Calculate the pH of a buffer solution that is 0.15 M HNO_2(aq) and 0.20 M $NaNO_2$(aq).

[***Answer:*** 3.49]

Self-Test 12.1B Calculate the pH of a buffer solution that is 0.040 M $NH_4Cl(aq)$ and 0.030 M $NH_3(aq)$.

The point of using a buffer is to stabilize a solution against changes in pH when a strong base or a strong acid is added. The next example shows how to calculate the effect of added acid or base on the pH of an acid buffer.

EXAMPLE 12.2 Calculating the pH change of a buffered solution

Suppose we dissolve 1.2 g of sodium hydroxide (0.030 mol NaOH) in 500. mL of the buffer solution described in Example 12.1. Calculate the pH of the resulting solution and the change in pH. Assume that the volume of the solution remains unchanged.

Anticipate Because the buffer solution contains a weak acid that will react with the strong base, we should expect only a small change in the pH from the 4.44 of the initial solution.

PLAN We solve this problem in two stages. First, we calculate the concentrations of acid and conjugate base by noting that the OH^- ions added to the buffer solution react with some of the acid of the buffer system, decreasing the amount of acid and correspondingly increasing the amount of conjugate base. Then we rearrange the expression for K_a to obtain the pH of the solution, just as in Example 12.1.

What should we assume? That the equilibrium concentrations of the acid and its conjugate base are nearly the same as their initial concentrations and that the neutralization reaction goes to completion.

SOLVE The proton transfer equilibrium is

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$

$$K_a = \frac{[H_3O^+][CH_3CO_2^-]}{[CH_3COOH]}$$

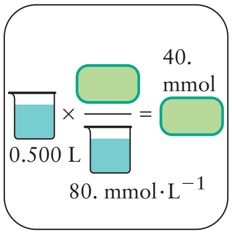
We use the data in Example 12.1, including $K_a = 1.8 \times 10^{-5}$. The OH^- from the added NaOH reacts with some of the CH_3COOH according to

$$CH_3COOH(aq) + OH^-(aq) \rightleftharpoons CH_3CO_2^-(aq) + H_2O(l)$$

Step 1 Find the new concentration of acid.

Find the initial amount of CH_3COOH in the solution from $n_J = V[J]$.

$$n(CH_3COOH)_{initial} = (0.500\ L) \times (0.080\ mol{\cdot}L^{-1}) = 0.040\ mol$$

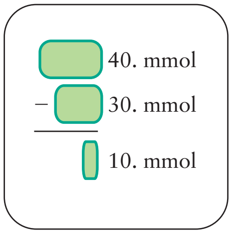


Calculate the amount of CH_3COOH that reacts by using 1 mol $CH_3COOH \simeq$ 1 mol OH^-.

$$n(CH_3COOH)_{reacts} = (0.030\ mol\ OH^-) \times \frac{1\ mol\ CH_3COOH}{1\ mol\ OH^-} = 0.030\ mol\ CH_3COOH$$

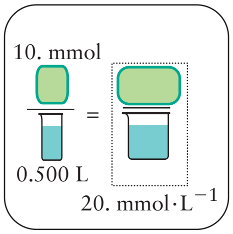
Calculate the amount of CH_3COOH remaining from $n_{final} = n_{initial} - n_{reacts}$.

$$n(CH_3COOH)_{final} = 0.040 - 0.030\ mol = 0.010\ mol$$



From $[J] = n_J/V$,

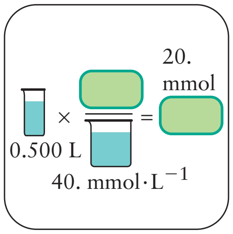
$$[CH_3COOH] = \frac{0.010\ \text{mol}}{0.500\ \text{L}} = 0.020\ \text{mol·L}^{-1}$$



Step 2 Find the new concentration of the conjugate base.

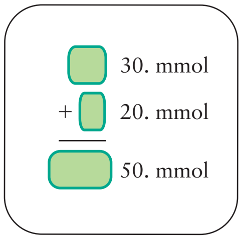
Find the initial amount of $CH_3CO_2^-$ in the solution from $n_J = V[J]$.

$$n(CH_3CO_2^-)_{\text{initial}} = (0.500\ \text{L}) \times (0.040\ \text{mol·L}^{-1}) = 0.020\ \text{mol}$$



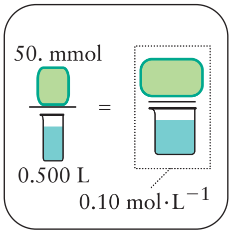
Add the change in the amount of $CH_3CO_2^-$ due to the reaction.

$$n(CH_3CO_2^-)_{\text{final}} = 0.020 + 0.030\ \text{mol} = 0.050\ \text{mol}$$



From $[J] = n_J/V$,

$$[CH_3CO_2^-] = \frac{0.050\ \text{mol}}{0.500\ \text{L}} = 0.10\ \text{mol·L}^{-1}$$



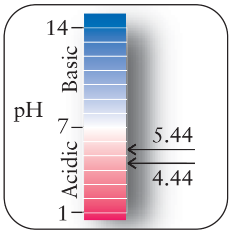
Step 3 Calculate the pH.

Calculate $[H_3O^+]$ from $[H_3O^+] = K_a[CH_3COOH]/[CH_3CO_2^-]$.

$$[H_3O^+] \approx (1.8 \times 10^{-5}) \times \frac{0.020}{0.10} = 3.6 \times 10^{-6}$$

From $\text{pH} = -\log [H_3O^+]$,

$$\text{pH} \approx -\log(3.6 \times 10^{-6}) \approx 5.44$$



Evaluate As expected, the pH of the solution changes only slightly, from about 4.4 to about 5.4.

Self-Test 12.2A Suppose that 0.0200 mol NaOH(s) is dissolved in 300. mL of the buffer solution of Example 12.1. Calculate the pH of the resulting solution and the change in pH.

[***Answer:*** 5.65, an increase of 1.21]

Self-Test 12.2B Suppose that 0.0100 mol HCl(g) is dissolved in 500. mL of the buffer solution of Example 12.1. Calculate the pH of the resulting solution and the change in pH.

Buffers are often prepared with equal molar concentrations of the conjugate acid and base because then there are adequate supplies of the “source” and “sink” species that

can stabilize the solution against change in either direction. The pH of these "equimolar" solutions is very easy to predict. Consider the equilibrium

$$HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq) \qquad K_a = \frac{[H_3O^+][A^-]}{[HA]} \qquad \textbf{(A)}$$

The values of [HA] and $[A^-]$ that appear in K_a are the equilibrium concentrations of acid and base in the solution, not the concentrations added initially. However, a weak acid HA typically loses only a tiny fraction of its protons, and so [HA] is negligibly different from the concentration of the acid used to prepare the buffer, $[HA]_{initial}$. Likewise, only a tiny fraction of the weakly basic anions A^- accept protons, and so $[A^-]$ is negligibly different from the initial concentration of the base used to prepare the buffer, $[A^-]_{initial}$. Because the two initial concentrations are the same, we can write

$$K_a \approx \frac{[H_3O^+][A^-]_{initial}}{[HA]_{initial}} = [H_3O^+]$$

It follows that when $[HA]_{initial} = [A^-]_{initial}$,

$$pH = pK_a \qquad \textbf{(1)*}$$

This very simple result makes it easy to make an initial choice of a buffer: we just select an acid that has a pK_a close to the pH that we require and prepare an equimolar solution with its conjugate base.

When we prepare a buffer for pH > 7 we have to remember that the acid is supplied by the salt, that the conjugate base is the base itself, and that the pK_a is that of the *conjugate acid* of the base (and hence related to the pK_b of the base by $pK_a + pK_b = pK_w$). Mixtures in which the conjugate acid and base have unequal concentrations—such as those considered in Examples 12.1 and 12.2—are buffers, but they may be less effective than those in which the concentrations are nearly equal (see Section 12.3). Table 12.1 lists some typical buffer systems.

Self-Test 12.3A Which of the buffer systems listed in Table 12.1 would be a good choice to prepare a buffer with pH close to 5?

[***Answer:*** $CH_3COOH/CH_3CO_2^-$]

Self-Test 12.3B Which of the buffer systems listed in Table 12.1 would be a good choice to prepare a buffer with pH close to 10?

We can lower the pH of an acid buffer solution by adding some weak acid. To raise the pH of an acid buffer we need to add some more of the acid's conjugate base by adding more salt. Alternatively, we could add some strong base (NaOH, for instance), to convert some of the acid to the salt. Commercially available buffer solutions can be purchased for virtually any desired pH. A buffer solution commonly used to calibrate pH meters contains 0.025 M $Na_2HPO_4(aq)$ and 0.025 M $KH_2PO_4(aq)$ and has pH = 6.87 at 25°C. However, the method demonstrated in Example 12.1 would give pH = 7.2 for this solution. Because our calculations interpret activities as molarities, not *effective* molarities, they ignore ion–ion interactions; so the values calculated are only approximate but are a reasonably good guide (and a good starting point for more elaborate calculations).

Many chemical reactions in our bodies take place in buffered environments. Biochemists studying these reactions commonly need to make quick estimates of pH by employing a form of the expression for K_a that gives the pH directly for any composition of the mixture, not just an equimolar mixture. For the equilibrium in reaction A, we can rearrange the expression for K_a into

$$[H_3O^+] = K_a \times \frac{[HA]}{[A^-]}$$

from which it follows, by taking the negative logarithms of both sides, that

$$\overbrace{-\log[H_3O^+]}^{pH} = \overbrace{-\log K_a}^{pK_a} - \log\frac{[HA]}{[A^-]}$$

TABLE 12.1 Typical Buffer Systems

Composition	pK_a
Acid buffers	
$CH_3COOH/CH_3CO_2^-$	4.75
HNO_2/NO_2^-	3.37
$HClO_2/ClO_2^-$	2.00
Base buffers	
NH_4^+/NH_3	9.25
$(CH_3)_3NH^+/(CH_3)_3N$	9.81
$H_2PO_4^-/HPO_4^{2-}$	7.21

Then, from $\log x = -\log(1/x)$,

$$pH = pK_a - \log\frac{[HA]}{[A^-]} = pK_a + \log\frac{[A^-]}{[HA]}$$

As we have discussed, [HA] can be approximated by $[HA]_{initial}$ (which we shall write $[acid]_{initial}$) and $[A^-]$ by $[A^-]_{initial}$ (which we shall write $[base]_{initial}$); the result is the **Henderson–Hasselbalch equation:**

$$pH = pK_a + \log\frac{[base]_{initial}}{[acid]_{initial}} \quad (2)^*$$

For an acetic acid/acetate buffer the expression takes the form

$$pH = pK_a + \log\frac{[CH_3CO_2^-]_{initial}}{[CH_3COOH]_{initial}}$$

Equation 2 can also be used for a basic buffer, with pK_a that of the conjugate acid of the base. For example, in the case of an ammonia buffer, we would use the pK_a of NH_4^+ and identify "base" with NH_3 and "acid" with NH_4^+. If only pK_b is available, we calculate pK_a by using Eq. 11b of Chapter 11 ($pK_a + pK_b = pK_w$). Therefore, for an ammonia/ammonium buffer we would write

$$pH = pK_a(NH_4^+) + \log\frac{[NH_3]_{initial}}{[NH_4^+]_{initial}}$$

A note on good practice: Keep in mind the approximations required for the use of the Henderson–Hasselbalch equation (that the concentrations of both the weak acid and its conjugate base are much greater than the hydronium ion concentration). Because the equation uses molar concentration instead of activities, it also ignores the interactions between ions and the numerical values it predicts must be treated with caution.

In practice, the Henderson–Hasselbalch equation is used to make rapid estimates of the pH of a mixed solution intended to be used as a buffer, and then the pH is adjusted to the precise value required by adding more acid or base and monitoring the solution with a pH meter.

EXAMPLE 12.3 Selecting the composition for a buffer solution with a given pH

Calculate the ratio of the molarities of CO_3^{2-} and HCO_3^- ions required to achieve buffering at pH = 9.50. The pK_{a2} of H_2CO_3 is 10.25.

Anticipate Because the desired pH is lower than the pK_{a2} of H_2CO_3, we need the logarithm to be negative. That will be the case when the ratio of concentrations is less than 1.

PLAN Rearrange the Henderson–Hasselbalch equation to solve for the ratio of the weak acid to its conjugate base.

What should we assume? As usual, we assume that activities can be approximated by molarities. As we have already illustrated, we also begin by assuming that the equilibrium concentrations of acid and its conjugate base can be approximated by their initial values.

SOLVE In the equilibrium $HCO_3^- + H_2O(l) \rightleftharpoons H_3O^+(aq) + CO_3^{2-}$, the acid is HCO_3^- and its conjugate base is CO_3^{2-}. From Section 11.16, we know that we can ignore any H_2CO_3 formed.

From $pH = pK_a + \log([base]_{initial}/[acid]_{initial})$,

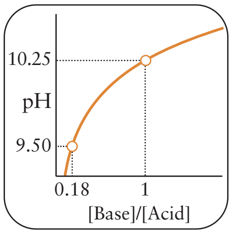
$$\log\frac{[base]}{[acid]} = pH - pK_a$$

Use the initial concentration of CO_3^{2-} for the base and that of HCO_3^- for the acid and substitute the values of pH and pK_a.

$$\log \frac{[CO_3^{2-}]}{[HCO_3^-]} = 9.50 - 10.25 = -0.75$$

Now use $x = 10^{\log x}$:

$$\frac{[CO_3^{2-}]}{[HCO_3^-]} = 10^{-0.75} = 0.18$$



Evaluate The solution acts as a buffer with a pH close to 9.50 if it is prepared by mixing the solutes in the ratio 0.18 mol CO_3^{2-} to 1.0 mol HCO_3^-. As expected, the ratio of concentrations is less than 1.

Self-Test 12.4A Calculate the ratio of the molarities of acetate ions and acetic acid needed to buffer a solution at pH = 5.25. The pK_a of CH_3COOH is 4.75.

[*Answer:* 3.2:1]

Self-Test 12.4B Calculate the ratio of the molarities of benzoate ions and benzoic acid (C_6H_5COOH) needed to buffer a solution at pH = 3.50. The pK_a of C_6H_5COOH is 4.19.

The pH of a buffer solution is close to the pK_a of the weak acid component when the acid and base have similar concentrations.

12.3 Buffer Capacity

Just as a sponge can hold only so much water, a buffer can mop up only so many hydronium ions. Its proton sources and sinks become exhausted if too much strong acid or base is added to the solution. **Buffer capacity** is the maximum amount of acid or base that can be added before the buffer loses its ability to resist large changes in pH. A buffer with a high capacity is able to maintain its buffering action against the addition of strong acid or base better than can one with only a small capacity. The buffer is exhausted when most of the weak base has been converted into its conjugate acid or when most of the weak acid has been converted into its conjugate base. A concentrated buffer solution has a greater capacity than the same volume of a more dilute solution of the same buffer.

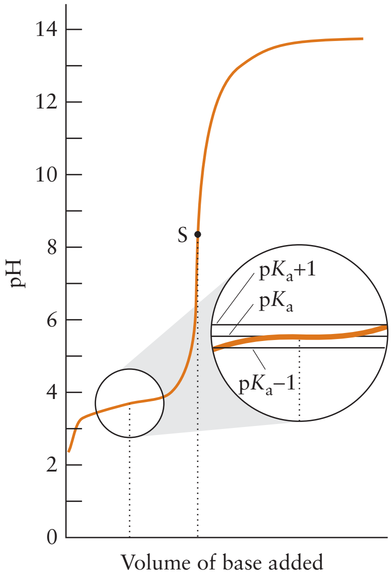


FIGURE 12.3 This plot shows how the pH of a weak acid changes as a strong base is added. When the conjugate acid and base are present at similar concentrations the curve is nearly horizontal, showing that the pH changes very little as more strong base or strong acid is added. As the inset shows, the pH lies between pK_a ± 1 across the buffer region. S denotes the stoichiometric point (Section L).

Buffer capacity also depends on the relative concentrations of weak acid and base. Broadly speaking, a buffer is found experimentally to have a high capacity for stabilizing against the addition of acid when the amount of weak base present is at least 10% of the amount of weak acid. Otherwise, the weak base is used up quickly as strong acid is added. Similarly, a buffer has a high capacity for stabilizing against the addition of base when the amount of weak acid present is at least 10% of the amount of weak base, because otherwise the weak acid is used up quickly as strong base is added.

We can use these percentages to express the range of buffer action in terms of the pH of the solution. The Henderson–Hasselbalch equation shows us that, when the acid is 10 times as abundant as the base ([acid] = 10[base]), the pH of the solution is

$$\text{pH} = \text{p}K_a + \log\frac{[\text{base}]}{10[\text{base}]} = \text{p}K_a + \log\frac{1}{10} = \text{p}K_a - 1 \quad \textbf{(3a)}$$

Likewise, when the base is 10 times as abundant as the acid ([base] = 10[acid]), the pH is

$$\text{pH} = \text{p}K_a + \log\frac{10[\text{acid}]}{[\text{acid}]} = \text{p}K_a + \log 10 = \text{p}K_a + 1 \quad \textbf{(3b)}$$

We see that the experimentally determined concentration range converts into a pH range of ±1. That is, the buffer acts most effectively when the pH is within a range of ±1 unit of pK_a (Fig. 12.3). For instance, because the pK_a of $H_2PO_4^-$ is 7.21, a

KH_2PO_4/K_2HPO_4 buffer can be expected to be most effective between about pH = 6.2 and pH = 8.2.

The composition of blood plasma, in which the concentration of HCO_3^- ions is about 20 times that of H_2CO_3, seems to be outside the range for optimum buffering. However, the principal waste products of living cells are carboxylic acids, such as lactic acid. Plasma, with its relatively high concentration of HCO_3^- ions, can absorb a significant surge of hydrogen ions from these carboxylic acids. The high proportion of HCO_3^- also helps us to withstand disturbances that lead to excess acid, such as disease and shock due to burns (Box 12.1).

The capacity of a buffer is determined by its concentration and pH. A more concentrated buffer can react with more added acid or base than can a less concentrated one. A buffer solution is generally most effective when the pH is in the range pK_a ± 1.

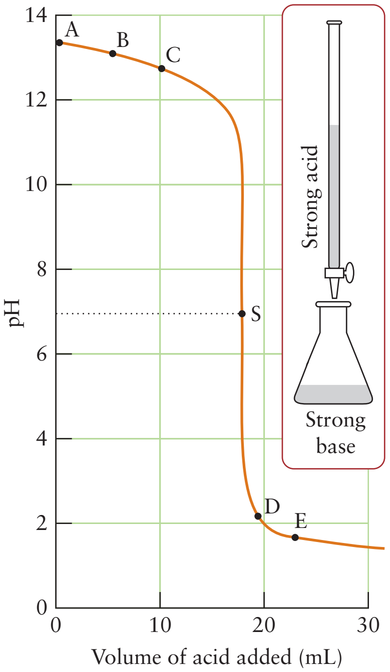

FIGURE 12.4 The variation of pH during the titration of a strong base, 25.00 mL of 0.250 M NaOH(aq), with a strong acid, 0.340 M HCl(aq). The stoichiometric point (S) occurs at pH = 7. The other points on the pH curve are explained in Example 12.4 in the text.

TITRATIONS

As we saw in Section L, titration involves the addition of a solution, called the *titrant*, from a buret to a flask containing a sample called the *analyte*. For example, if an environmental chemist is monitoring acid mine drainage and needs to know the concentration of acid in the water, a sample of the effluent from the mine would be the analyte and a solution of base of known concentration would be the titrant. At the *stoichiometric point*, the amount of OH^- (or H_3O^+) added as titrant is equal to the amount of H_3O^+ (or OH^-) initially present in the analyte. We use the techniques in this chapter to identify the roles of different species in determining the pH of the analyte solution at any stage of a titration and to select the appropriate indicator for the titration.

12.4 Strong Acid–Strong Base Titrations

When a strong acid is mixed with a strong base in water, a neutralization reaction occurs for which the net ionic equation is

$$H_3O^+(aq) + OH^-(aq) \longrightarrow 2\,H_2O(l)$$

However, it is best to use the full chemical equation when working with titrations to ensure the correct stoichiometry. For example, if hydrochloric acid is used to neutralize $Ca(OH)_2$, we must take into account the fact that each formula unit of $Ca(OH)_2$ provides two OH^- ions:

$$2\,HCl(aq) + Ca(OH)_2(aq) \longrightarrow CaCl_2(aq) + 2\,H_2O(l)$$

A plot of the pH of the analyte solution against the volume of titrant added during a titration is called a **pH curve**. The shape of the pH curve in Fig. 12.4 is typical of titrations in which a strong acid is added to a strong base. Initially, the pH falls slowly. Then, at the stoichiometric point, there is a sudden decrease in pH through 7. At this point, an indicator changes color or an automatic titrator responds electronically to the sudden change in pH. Titrations typically end at this point. However, if we were to continue the titration, we would find that the pH falls slowly toward the value of the acid itself as the dilution due to the original analyte solution becomes less and less important.

Figure 12.5 shows a pH curve for a titration in which the analyte is a strong acid and the titrant is a strong base. This curve is the mirror image of the curve for the titration of a strong base with a strong acid.

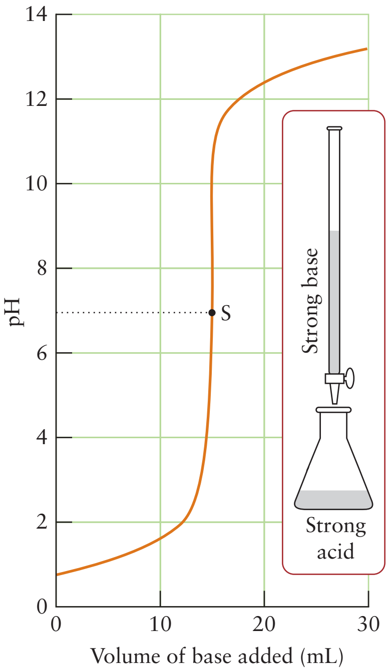

FIGURE 12.5 The variation of pH during a typical titration of a strong acid (the analyte) with a strong base (the titrant). The stoichiometric point (S) occurs at pH = 7.

BOX 12.1 WHAT HAS THIS TO DO WITH . . . STAYING ALIVE?

Physiological Buffers

Buffer systems are so vital to the existence of living organisms that the most immediate threat to the survival of a person with severe injury or burns is a change in blood pH. One of a paramedic's first steps in saving a life is to administer intravenous fluids.

Metabolic processes normally maintain the pH of human blood within a narrow range (7.35–7.45). To control blood pH, the body uses primarily the carbonic acid/hydrogen carbonate (bicarbonate) ion system. The normal ratio of HCO_3^- to H_2CO_3 in the blood is 20:1, with most of the carbonic acid in the form of dissolved CO_2. When the concentration of HCO_3^- increases further relative to that of H_2CO_3, blood pH rises. If the pH rises above the normal range, the condition is called *alkalosis*. Conversely, blood pH decreases when the ratio decreases; and when blood pH falls below the normal range, the condition is called *acidosis*. Because these conditions are life threatening and death can result within minutes, it is critical that the cause of the pH imbalance be identified and treated quickly.

Patients who have suffered traumatic injuries must receive an immediate intravenous solution to combat the symptoms of shock and help maintain the pH of blood.

The body maintains blood pH by two primary mechanisms: respiration and excretion. Carbonic acid concentration is controlled by respiration: as we exhale, we deplete our system of CO_2 and hence deplete it of H_2CO_3, too. This decrease in acid concentration raises the blood pH. Breathing faster and more deeply increases the amount of CO_2 exhaled and hence decreases the carbonic acid concentration in the blood, which in turn raises the blood pH. Hydrogen carbonate ion concentration is controlled by its rate of excretion in urine.

Respiratory acidosis results when decreased respiration raises the concentration of CO_2 in the blood. Asthma, pneumonia, emphysema, or inhaling smoke can all cause respiratory acidosis. So can any condition that reduces a person's ability to breathe. Respiratory acidosis is usually treated with a mechanical ventilator, to assist the victim's breathing. The improved exhalation increases the excretion of CO_2 and raises blood pH. In many cases of asthma, chemicals can facilitate respiration by opening constricted bronchial passages.

Metabolic acidosis is caused by the release into the bloodstream of excessive amounts of lactic acid and other acidic by-products of metabolism. These acids enter the bloodstream, react with hydrogen carbonate ion to produce H_2CO_3, and shift the ratio HCO_3^-/H_2CO_3 to a lower value. Heavy exercise, diabetes, and fasting can all produce metabolic acidosis. The normal response of the body is to increase the rate of breathing to eliminate some of the CO_2. Thus, we pant heavily when running uphill.

Metabolic acidosis can also result when a person is severely burned. Blood plasma leaks from the circulatory system into the injured area, producing edema (swelling) and reducing the blood volume. If the burned area is large, this loss of blood volume may be sufficient to reduce blood flow and oxygen supply to all the body's tissues. Lack of oxygen, in turn, causes the tissues to produce an excessive amount of lactic acid and leads to metabolic acidosis. To minimize the decrease in pH, the injured person breathes harder to eliminate the excess CO_2. However, if blood volume drops below levels for which the body can compensate, a vicious circle ensues in which blood flow decreases still further, blood pressure falls, CO_2 excretion diminishes, and acidosis becomes more severe. People in this state are said to be in shock and will die if not treated promptly.

The dangers of shock are avoided or treated by intravenous infusion of large volumes of a salt-containing solution that is isotonic with blood (has the same osmotic pressure as blood), usually one known as *lactated Ringer's solution*. The added liquid increases blood volume and blood flow, thereby improving oxygen delivery. The $[HCO_3^-]/[H_2CO_3]$ ratio then increases toward normal and allows the severely injured person to survive.

Respiratory alkalosis is the rise in pH associated with excessive respiration. Hyperventilation, which can result from anxiety or high fever, is a common cause. The body may control blood pH during hyperventilation by fainting, which results in slower respiration. An intervention that may prevent fainting is to have a hyperventilating person breathe into a paper bag, which allows much of the respired CO_2 to be taken up again.

Metabolic alkalosis is the increase in pH resulting from illness or chemical ingestion. Repeated vomiting or the overuse of diuretics can cause metabolic alkalosis. Once again the body compensates, this time by decreasing the rate of respiration.

TOOLBOX 12.1 HOW TO CALCULATE THE pH DURING A STRONG ACID–STRONG BASE TITRATION

CONCEPTUAL BASIS

The variation of pH during the titration of a strong acid with a strong base is governed by the major species in solution. Because the conjugate base of the strong acid has little effect on the pH, the pH is determined by whichever is in excess, the strong acid or the strong base.

PROCEDURE

First, use the reaction stoichiometry to find the amount of excess acid or base.

Step 1 Calculate the amount of H_3O^+ ions (if the analyte is a strong acid) or OH^- ions (if the analyte is a strong base) in the original analyte solution from the product of the analyte's molarity and its volume. Use $n_J = V[J]$, where J is H_3O^+ or OH^-.

Step 2 Calculate the amount of OH^- ions (if the titrant is a strong base) or H_3O^+ ions (if the titrant is a strong acid) in the volume of titrant added from the product of the titrant's molarity and its volume. Use $n_J = V[J]$, where J is OH^- or H_3O^+.

Step 3 Write the chemical equation for the neutralization reaction and use the reaction stoichiometry to find the amount of H_3O^+ ions (or OH^- ions if the analyte is a strong base) that remains in the analyte solution after all the added titrant reacts. Then subtract from the initial amount the amount of H_3O^+ or OH^- ions that has reacted.

Next, determine the concentration.

Step 4 Use the remaining amount of H_3O^+ (or OH^-) and the total volume of the combined solutions, $V = V_{analyte} + V_{titrant}$, to find the molarity of the H_3O^+ (or OH^-) ions in the solution from $[J] = n_J/V$.

Finally, calculate the pH.

Step 5 If acid is in excess, take the negative logarithm of the H_3O^+ molarity to find the pH. If base is in excess, find the pOH, and then convert pOH into pH by using the relation $pH + pOH = pK_w$.

This procedure is illustrated in Example 12.4.

EXAMPLE 12.4 Calculating points on the pH curve for a strong acid–strong base titration

Suppose we are carrying out a titration in which the analyte initially consists of 25.00 mL of 0.250 M NaOH(aq) and the titrant is 0.340 M HCl(aq). Calculate (a) the pH of the original analyte solution and (b) the new pH after the addition of 5.00 mL of the acid titrant.

Anticipate We should expect the pH to decrease slightly from its initial value as acid is added.

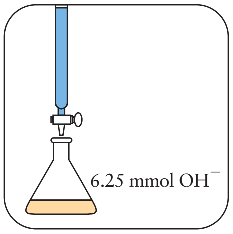
PLAN For part (a) determine the pOH of the solution and convert it to the pH. For part (b) follow the procedure outlined in Toolbox 12.1.

What should we assume? That there is so much acid or base present that the autoprotolysis of water does not contribute to the pH.

SOLVE (a) Initially, the pOH of the analyte is pOH = –log 0.250 = 0.602, and so the pH of the solution is pH = 14.00 − 0.602 = 13.40. This is point A in Fig. 12.4. (b) We now follow the procedure in Toolbox 12.1.

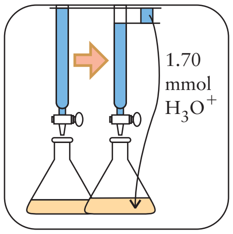
Step 1 Find the amount of OH^- ions initially present from $n_J = V[J]$.

$$n(OH^-) = (25.00 \times 10^{-3}\,L) \times (0.250\,mol\cdot L^{-1})$$
$$= 6.25 \times 10^{-3}\,mol$$
$$= 6.25\,mmol$$



Step 2 Find the amount of H_3O^+ ions supplied by the titrant from $n_J = V[J]$.

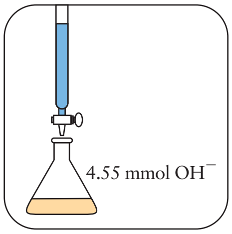
$$n(H_3O^+) = (5.00 \times 10^{-3}\,L) \times (0.340\,mol\cdot L^{-1})$$
$$= 1.70 \times 10^{-3}\,mol$$
$$= 1.70\,mmol$$



Step 3 Write the balanced equation for the neutralization reaction.

$$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$$

Find the amount of OH^- remaining from 1 mol NaOH ≏ 1 mol HCl, after reaction of all the added H_3O^+ ions.

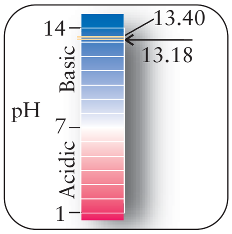


$$n(OH^-)_{final} = 6.25 - 1.70 \text{ mmol} = 4.55 \text{ mmol}$$

Step 4 Find the concentration of OH^- ions from the total volume of the solution and $[J] = n_J/V$.

$$[OH^-] = \frac{4.55 \times 10^{-3} \text{ mol}}{(25.00 + 5.00) \times 10^{-3} \text{ L}} = 0.152 \text{ mol·L}^{-1}$$

Step 5 Calculate the pH from $pOH = -\log [OH^-]$ and then $pH = pK_w - pOH$.



$$pOH = -\log(0.152) = 0.82, \qquad pH = 14.00 - 0.82 = 13.18$$

This is point B in Fig. 12.4.

Evaluate Note that the pH has fallen, as expected, but only by a very small amount. This small change is consistent with the shallow slope of the pH curve at the start of the titration.

Self-Test 12.5A What is the pH of the solution that results from the addition of a further 5.00 mL of the HCl(aq) titrant to the analyte?

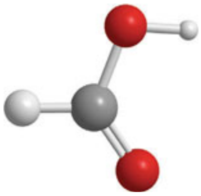
[***Answer:*** 12.91, point C]

Self-Test 12.5B What is the pH of the solution that results from the addition of yet another 2.00 mL of titrant to the analyte?

Experimentally, we know that the pH changes abruptly close to the stoichiometric point. Suppose we reach the stoichiometric point in the titration described in Example 12.4 and then add an additional 1.00 mL of HCl(aq). To find out by how much the pH changes, we work through the steps in Toolbox 12.1 as in Example 12.4, except that now the acid is in excess. We find that, after the addition, the pH has fallen to 2.1 (point D in Fig. 12.4). This point is well below the pH (of 7) at the stoichiometric point, although only 1 mL more acid has been added.

In the titration of a strong acid with a strong base or of a strong base with a strong acid, the pH changes slowly initially, changes rapidly through pH = 7 at the stoichiometric point, and then changes slowly again.

12.5 Strong Acid–Weak Base and Weak Acid–Strong Base Titrations



1 Formic acid

In many titrations, one solution—either the analyte or the titrant—contains a weak acid or base and the other solution contains a strong base or acid. For example, if we want to know the concentration of formic acid, the weak acid found in ant venom (**1**), we can titrate it with sodium hydroxide, a strong base. Alternatively, to find the concentration of ammonia, a weak base, we titrate it with hydrochloric acid, a strong acid. Weak acids are not normally titrated with weak bases, because the stoichiometric point is too difficult to locate.

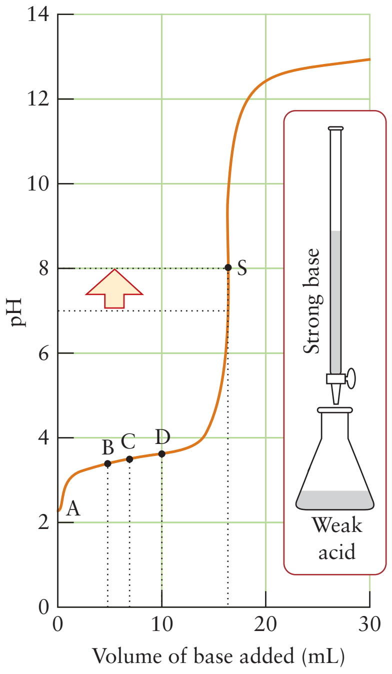


FIGURE 12.6 The pH curve for the titration of a weak acid with a strong base: 25.00 mL of 0.100 M HCOOH(aq) with 0.150 M NaOH(aq). The stoichiometric point (S) occurs at pH > 7 because the anion HCO_2^- is a base. The other points on the curve are explained in the text and in Example 12.6.

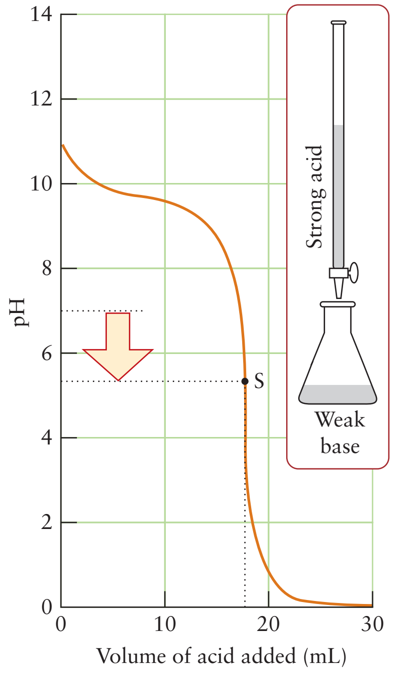

FIGURE 12.7 A typical pH curve for the titration of a weak base with a strong acid. The stoichiometric point (S) occurs at pH < 7 because the salt formed by the neutralization reaction has an acidic cation.

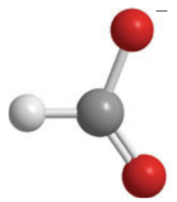
Figures 12.6 and 12.7 show the different pH curves that are found experimentally for these two types of titrations. Notice that the stoichiometric point does not occur at pH = 7. Moreover, although the pH changes reasonably sharply near the stoichiometric point, it does not change as abruptly as it does in a strong acid–strong base titration.

The pH at the stoichiometric point depends on the type of salt produced in the neutralization reaction. In the titration of formic acid, HCOOH, with sodium hydroxide the following reaction takes place:

$$HCOOH(aq) + NaOH(aq) \longrightarrow NaHCO_2(aq) + H_2O(l)$$

At the stoichiometric point the solution consists of sodium formate, $NaHCO_2$, and water. Because Na^+ ions have virtually no effect on pH and the formate ion, HCO_2^- (**2**), is a base, overall the solution is basic and pH > 7. The same is true for the stoichiometric point of the titration of any weak acid with strong base. At the stoichiometric point of the titration of aqueous ammonia with hydrochloric acid, the solute is ammonium chloride. Because Cl^- ions have virtually no effect on the pH and NH_4^+ is an acid, we expect pH < 7. The same is true for the stoichiometric point of the titration of any weak base with strong acid.



2 Formate ion

EXAMPLE 12.5 Estimating the pH at the stoichiometric point of the titration of a weak acid with a strong base

Estimate the pH at the stoichiometric point of the titration of 25.00 mL of 0.100 M HCOOH(aq) with 0.150 M NaOH(aq).

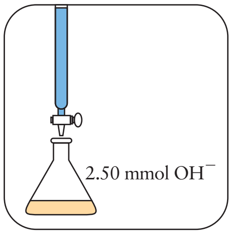
Anticipate Decide whether the salt present at the stoichiometric point provides an ion that acts as a weak base or as a weak acid. If the former, expect pH > 7; if the latter, expect pH < 7. In this case, the anion of the salt is basic, so we should expect pH > 7.

PLAN To calculate the pH at the stoichiometric point, proceed as in Example 11.10 or 11.11, noting that the amount of salt at the stoichiometric point is equal to the initial amount of acid and the volume is the total volume of the combined analyte and titrant solutions. The K_b of a weak base is related to the K_a of its conjugate acid by $K_a \times K_b = K_w$; K_a is listed in Table 11.1.

What should we assume? That the autoprotolysis of water has no significant effect on the pH.

SOLVE The salt present at the stoichiometric point, sodium formate, provides basic formate ions, and so we expect pH > 7. From Table 11.1, $K_a = 1.8 \times 10^{-4}$ for formic acid; therefore, $K_b = K_w/K_a = 5.6 \times 10^{-11}$.

Find the initial amount of HCOOH in the analyte from $n_J = V[J]$



$$n(\text{HCOOH}) = (2.500 \times 10^{-2}\ \text{L}) \times (0.100\ \text{mol·L}^{-1})$$
$$= 2.50 \times 10^{-3}\ \text{mol, or } 2.50\ \text{mmol}$$

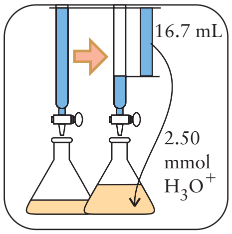
Find the amount of OH^- required to react with the HCOOH from the reaction stoichiometry, 1 mol $OH^- \simeq$ 1 mol HCOOH.

$$n(\text{OH}^-) = (2.50 \times 10^{-3}\ \text{mol HCOOH}) \times \frac{1\ \text{mol OH}^-}{1\ \text{mol HCOOH}}$$
$$= 2.50 \times 10^{-3}\ \text{mol OH}^- \qquad (\text{or } 2.50\ \text{mmol OH}^-)$$

The amount of HCO_2^- in the solution at the stoichiometric point is the same as the amount of OH^- added.

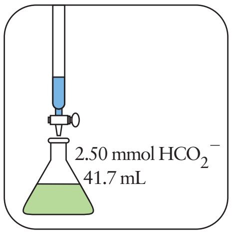
$$n(\text{HCO}_2^-) = 2.50\ \text{mmol}$$

Find the volume of titrant containing this amount of OH^- ions, from $V = n_J/[J]$.



$$V_{\text{added}} = \frac{2.50 \times 10^{-3}\ \text{mol}}{0.150\ \text{mol·L}^{-1}}$$
$$= 1.67 \times 10^{-2}\ \text{L or } 16.7\ \text{mL}$$

Find the total volume of the solution at the stoichiometric point from $V_{\text{final}} = V_{\text{initial}} + V_{\text{added}}$.



$$V_{\text{final}} = 25.00 + 16.7\ \text{mL}$$
$$= 41.7\ \text{mL}$$

Find the concentration of HCO_2^- ions at the stoichiometric point from $[J] = n_J/V$.

$$[\text{HCO}_2^-] = \frac{2.50 \times 10^{-3}\ \text{mol}}{4.17 \times 10^{-2}\ \text{L}} = 0.0600\ \text{mol·L}^{-1}$$

Now that we know the composition of the solution at the stoichiometric point, we can calculate the pH of the solution as described in Toolbox 11.2. The equilibrium to consider is

$$\text{HCO}_2^-(\text{aq}) + \text{H}_2\text{O(l)} \rightleftharpoons \text{HCOOH(aq)} + \text{OH}^-(\text{aq}) \qquad K_b = \frac{[\text{HCOOH}][\text{OH}^-]}{[\text{HCO}_2^-]}$$

The equilibrium table, with all concentrations in moles per liter, is

	HCO_2^-	HCOOH	OH^-
Step 1 Initial molarity	0.0600	0	0
Step 2 Change in molarity	$-x$	$+x$	$+x$
Step 3 Equilibrium molarity	$0.0600 - x$	x	x

Step 4 From $K_b = [HCOOH][OH^-]/[HCO_2^-]$,

$$5.6 \times 10^{-11} = \frac{x \times x}{0.0600 - x}$$

Provided $x \ll 0.0600$, the approximate form of this expression is:

$$5.6 \times 10^{-11} \approx \frac{x^2}{0.0600}$$

The solution is:

$$x \approx (5.6 \times 10^{-11} \times 0.0600)^{1/2} = 1.8 \times 10^{-6}$$

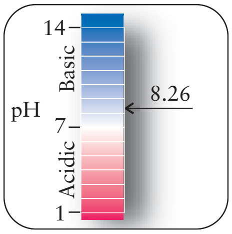
It follows from step 3 that the concentration of OH^- is 1.8 μmol·L^{-1}, which is about 18 times as great as the concentration of OH^- ions from the autoprotolysis of water (0.10 μmol·L^{-1}), and so ignoring the latter is reasonable. Now we can write

$$\text{pOH} = -\log(1.8 \times 10^{-6}) = 5.74$$

and therefore,

From pH + pOH = pK_w,

$$\text{pH} = 14.00 - 5.74$$
$$= 8.26 \text{ or about } 8.3$$



Evaluate At the stoichiometric point, pH > 7 as we expected.

Self-Test 12.6A Calculate the pH at the stoichiometric point of the titration of 25.00 mL of 0.010 M HClO(aq) with 0.020 M KOH(aq). See Table 11.1 for K_a.

[***Answer:*** 9.67]

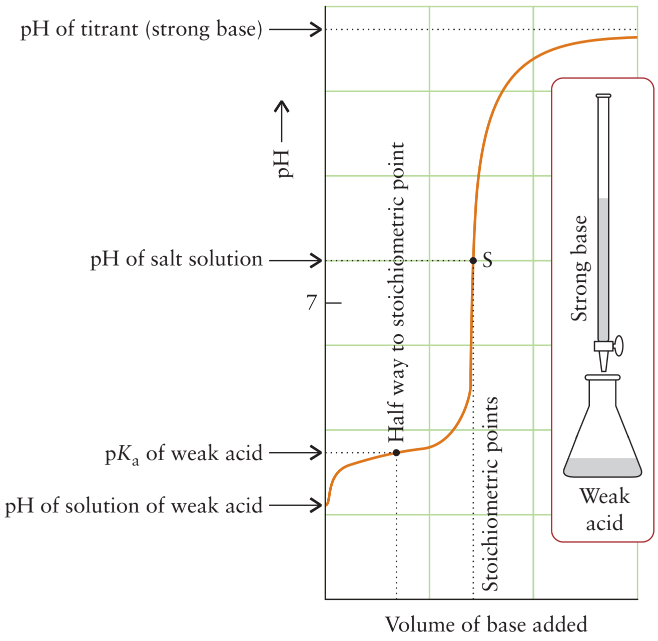
Self-Test 12.6B Calculate the pH at the stoichiometric point of the titration of 25.00 mL of 0.020 M NH_3(aq) with 0.015 M HCl(aq). (For NH_4^+, $K_a = 5.6 \times 10^{-10}$.)

Now consider the overall shape of the pH curve. The slow change in pH about halfway to the stoichiometric point indicates that the solution acts as a buffer in that region (see Fig. 12.3). At the halfway point of the titration, [HA] = [A^-] and pH = pK_a. In fact, one way to prepare a buffer is to neutralize half the amount of weak acid present with strong base. The flatness of the curve near pH = pK_a illustrates very clearly the ability of a buffer solution to stabilize the pH of the solution. Moreover, we can now see how to determine pK_a: plot the pH curve during a titration, identify the pH halfway to the stoichiometric point, and set pK_a equal to that pH (Fig. 12.8). To obtain the pK_b of a weak base, we find pK_a in the same way but then find pK_b from pK_a + pK_b = pK_w. The values recorded in Tables 11.1 and 11.2 were obtained in this way.

Well after the stoichiometric point in the titration of a weak acid with a strong base, the pH depends only on the concentration of excess strong base. For example, suppose we went on to add several liters of strong base from a giant buret. The presence of salt produced by the neutralization reaction would be negligible relative to the concentration of excess base. The pH would be that of the nearly pure titrant (the original base solution).

We have already seen how to estimate the pH of the initial analyte when only weak acid or weak base is present (point A in Fig. 12.6, for instance), as well as the pH at the stoichiometric point (point S). Between these two points lie points corresponding to a mixed solution of some weak acid (or base) and some salt. We can therefore use the techniques described in Toolbox 12.2 and Example 12.6 to account for the shape of the curve.

FIGURE 12.8 The pK_a of an acid can be determined by carrying out a titration of the weak acid with a strong base and locating the pH of the solution after the addition of half the volume of base needed to reach the stoichiometric point. The pH at that point is equal to the pK_a of the acid.



TOOLBOX 12.2 HOW TO CALCULATE THE pH DURING A TITRATION OF A WEAK ACID OR A WEAK BASE

CONCEPTUAL BASIS

The pH is governed by the major solute species present in solution. As strong base is added to a solution of a weak acid, a salt of the conjugate base of the weak acid is formed. This salt affects the pH and needs to be taken into account, as in a buffer solution. Table 12.2 outlines the regions encountered during a titration and the primary equilibrium to consider in each region.

PROCEDURE

The procedure is like that in Toolbox 12.1, except that an additional step is required to calculate the pH from the proton transfer equilibrium.

Use the reaction stoichiometry to find the amount of excess acid or base.

Begin by writing the chemical equation for the reaction, then:

Step 1 Calculate the amount of weak acid or base in the original analyte solution. Use $n_J = V_{analyte}[J]$.

Step 2 Calculate the amount of OH^- ions (or H_3O^+ ions if the titrant is an acid) in the volume of titrant added. Use $n_J = V_{titrant}[J]$.

Step 3 Use the reaction stoichiometry to calculate the following amounts:

- Weak acid/strong base titration: the amount of conjugate base formed in the neutralization reaction, and the amount of weak acid remaining.
- Weak base/strong acid titration: the amount of conjugate acid formed in the neutralization reaction, and the amount of weak base remaining.

Determine the concentration.

Step 4 Find the "initial" molarities of the conjugate acid and base in solution after neutralization, but before any reaction with water is taken into account. Use $[J] = n_J/V$, where V is the total volume of the solution, $V = V_{analyte} + V_{titrant}$.

Determine the pH.

Step 5 Use an equilibrium table to find the H_3O^+ concentration in a weak acid or the OH^- concentration in a weak base. Alternatively, if the concentrations of conjugate acid and base calculated in step 4 are both large relative to the concentration of hydronium ions, use them in the expression for K_a or the Henderson–Hasselbalch equation to determine the pH. In each case, if the pH is less than 6 or greater than 8, assume that the autoprotolysis of water does not significantly affect the pH. If necessary, convert between K_a and K_b by using $K_w = K_a \times K_b$.

This procedure is illustrated in Example 12.6.

TABLE 12.2 Summary of Weak Acid and Weak Base Titration Equilibria

Point in titration	Primary species	Proton transfer equilibrium	Related Toolbox
1 Weak acid HA titrated with strong base			
initial	HA	$HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq)$	11.1
buffer region	HA, A^-	$HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq)$	12.2
stoichiometric point*	A^-	$A^-(aq) + H_2O(l) \rightleftharpoons HA(aq) + OH^-(aq)$	11.2
2 Weak base B titrated with strong acid			
initial	B	$B(aq) + H_2O(l) \rightleftharpoons HB^+(aq) + OH^-(aq)$	11.2
buffer region	B, HB^+	$B(aq) + H_2O(l) \rightleftharpoons HB^+(aq) + OH^-(aq)$	12.2
stoichiometric point†	HB^+	$HB^+(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + B(aq)$	11.1

*This is a solution of a salt with a basic anion.
†This is a solution of a salt with an acidic cation.

EXAMPLE 12.6 Calculating the pH before the stoichiometric point in a weak acid–strong base titration

Calculate the pH of (a) 0.100 M HCOOH(aq) and (b) the solution resulting when 5.00 mL of 0.150 M NaOH(aq) is added to 25.00 mL of the acid. Use $K_a = 1.8 \times 10^{-4}$ for HCOOH.

Anticipate When the strong base is added, some of the weak acid is neutralized, so we expect the pH to rise from (a) to (b).

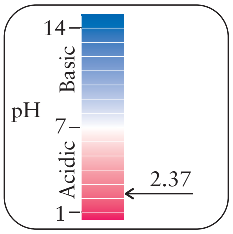
PLAN For (a) we use the procedure in Toolbox 11.1. For (b) we find the pH using the procedure in Toolbox 12.2.

What should we assume? That the autoprotolysis of water does not contribute significantly to the pH; also, the weak acid formic acid undergoes only a small degree of deprotonation.

SOLVE

(a) From $[H_3O^+] = (K_a[HA])^{1/2}$ and $pH = -\log [H_3O^+]$,

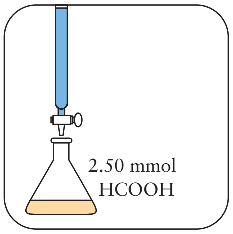
$$pH = -\log (1.8 \times 10^{-4} \times 0.100)^{1/2}$$
$$= 2.37$$



(b) The chemical equation is $HCOOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + HCO_2^-(aq)$.

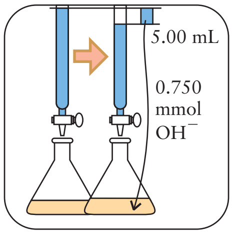
Step 1 Find the initial amount of HCOOH from $n_J = V[J]$.

$$n(HCOOH) = (2.500 \times 10^{-2}\ L) \times (0.100\ mol{\cdot}L^{-1})$$
$$= 2.50 \times 10^{-3}\ mol\ (2.50\ mmol)$$



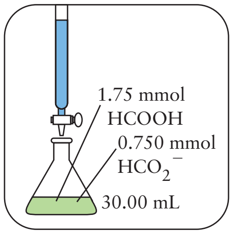
Step 2 Find the amount of OH^- added from $n_J = V[J]$

$$n(OH^-) = (5.00 \times 10^{-3}\ L) \times (0.150\ mol{\cdot}L^{-1})$$
$$= 7.50 \times 10^{-4}\ mol\ (0.750\ mmol)$$



Step 3 Find the amounts of HCOOH and HCO_2^- after neutralization from 1 mol $OH^- \simeq$ 1 mol HCOOH and 1 mol $OH^- \simeq$ 1 mol HCO_2^-.

0.750 mmol OH^- produces 0.750 mmol HCO_2^- and leaves
2.50 − 0.750 mmol = 1.75 mmol HCOOH



Step 4 Find the concentrations of acid and conjugate base from $[J] = n_J/V$, where the total volume is $V = V_{analyte} + V_{titrant}$.

$$[HCOOH] = \frac{1.75 \times 10^{-3}\ mol}{(25.00 + 5.00) \times 10^{-3}\ L} = 0.0583\ mol{\cdot}L^{-1}$$

$$[HCO_2^-] = \frac{7.50 \times 10^{-4}\ mol}{(25.00 + 5.00) \times 10^{-3}\ L} = 0.0250\ mol{\cdot}L^{-1}$$

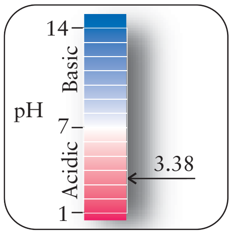
Step 5 Now we evaluate the pH. The proton transfer equilibrium for HCOOH in water is

$$HCOOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + HCO_2^-(aq)$$

From Table 11.1, the pK_a for formic acid is 3.75. Assuming little change in the concentrations of acid and base due to the deprotonation of HCOOH, we write

From $pH = pK_a + \log([HCO_2^-]/[HCOOH])$,

$$pH = 3.75 + \log\frac{0.0250}{0.0583}$$
$$= 3.38$$



Evaluate pH = 3.38 corresponds to $[H_3O^+] = 4.2 \times 10^{-4}$, point B in Fig. 12.6 and, as expected, the contribution of autoprotolysis is negligible. As predicted, the pH of the mixed solution (3.38) is higher than that of the original acid (2.37).

Self-Test 12.7A Calculate the pH of the solution after the addition of another 5.00 mL of 0.150 M NaOH(aq).

[***Answer:*** 3.93, point D]

Self-Test 12.7B Calculate the pH of the solution after the addition of yet another 5.00 mL of 0.150 M NaOH(aq).

Figure 12.8 summarizes the changes in pH of a solution during a titration of a weak acid by a strong base. Half way to the stoichiometric point, the pH is equal to the pK_a of the acid. The pH is greater than 7 at the stoichiometric point of the titration of a weak acid and strong base. The pH is less than 7 at the stoichiometric point of the titration of a weak base and strong acid.

12.6 Acid–Base Indicators

A simple, reliable, and fast method of determining the pH of a solution and of monitoring a titration is with a **pH meter,** which uses a special electrode to measure H_3O^+ concentration. An automatic titrator uses an internal pH meter to monitor the pH of the analyte solution continuously. It detects the stoichiometric point by responding to the characteristic rapid change in pH (Fig. 12.9). Another common technique is to use an indicator to detect the stoichiometric point. An **acid–base indicator** is a water-soluble organic dye with a color that depends on the pH. The sudden change in pH that occurs at the stoichiometric point of a titration is signaled by a sharp change in color of the dye as it responds to the pH.

FIGURE 12.9 A commercially available automatic titrator. The stoichiometric point of the titration is detected by the sudden change in pH that occurs in its vicinity; the pH is monitored electronically. The pH curve can be plotted as the reaction proceeds, as shown on the monitor screen.

TABLE 12.3 Indicator Color Changes*

Indicator	pK_{In}	pH range of color change	Color of acid form	Color of base form
thymol blue	1.7	1.2 to 2.8	red	yellow
methyl orange	3.4	3.2 to 4.4	red	yellow
bromophenol blue	3.9	3.0 to 4.6	yellow	blue
bromocresol green	4.7	3.8 to 5.4	yellow	blue
methyl red	5.0	4.8 to 6.0	red	yellow
litmus	6.5	5.0 to 8.0	red	blue
bromothymol blue	7.1	6.0 to 7.6	yellow	blue
phenol red	7.9	6.6 to 8.0	yellow	red
thymol blue	8.9	8.0 to 9.6	yellow	blue
phenolphthalein	9.4	8.2 to 10.0	colorless	pink
alizarin yellow R	11.2	10.1 to 12.0	yellow	red
alizarin	11.7	11.0 to 12.4	red	purple

*The colors of the acid and base forms are only a symbolic representation of the actual colors.

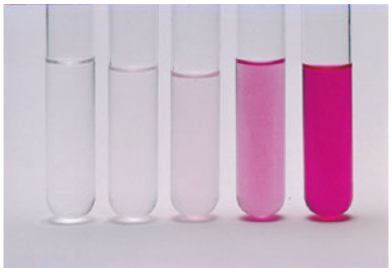


FIGURE 12.10 The stoichiometric point of an acid–base titration may be detected by the color change of an indicator. Here we see the colors of solutions containing a few drops of phenolphthalein at (from left to right) pH of 7.0, 8.5, 9.4 (its end point), 9.8, and 12.0. At the end point, the concentrations of the conjugate acid and base forms of the indicator are equal.

An acid–base indicator changes color with pH because it is a weak acid that has one color in its acid form (HIn, where In stands for indicator) and another color in its conjugate base form (In^-). The color change results because the proton in HIn changes the structure of the molecule in such a way that the light absorption characteristics of HIn are different from those of In^-. When the concentration of HIn is much greater than that of In^-, the solution has the color of the acid form of the indicator. When the concentration of In^- is much greater than that of HIn, the solution has the color of the base form of the indicator.

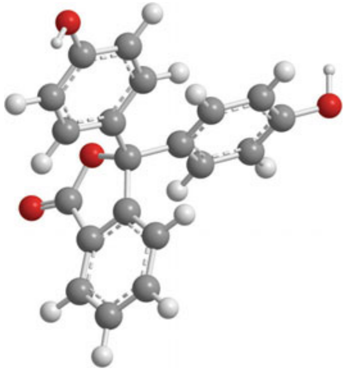
Because it is a weak acid, an indicator takes part in a proton transfer equilibrium:

$$\mathrm{HIn(aq)} + \mathrm{H_2O(l)} \rightleftharpoons \mathrm{H_3O^+(aq)} + \mathrm{In^-(aq)} \qquad K_a = \frac{[\mathrm{H_3O^+}][\mathrm{In^-}]}{[\mathrm{HIn}]}$$

The **end point** of an indicator is the point at which the concentrations of its acid and base forms are equal: $[\mathrm{HIn}] = [\mathrm{In^-}]$. When we substitute this equality into the expression for K_{In}, we see that at the end point $[\mathrm{H_3O^+}] = K_{In}$. That is, the color change occurs when

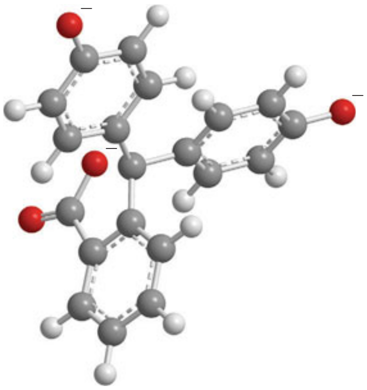
$$\mathrm{pH} = \mathrm{p}K_{In} \qquad (4)^*$$

The color starts to change perceptibly about 1 pH unit before $\mathrm{p}K_{In}$ and is effectively complete about 1 pH unit after $\mathrm{p}K_{In}$. Table 12.3 gives the values of $\mathrm{p}K_{In}$ for a number of common indicators.



3

One common indicator is phenolphthalein (Fig. 12.10). The acid form of this large molecule (**3**) is colorless; its conjugate base form (**4**) is pink. The structure of the base form of phenolphthalein allows electrons to be delocalized across all three of the benzenelike rings, and the increase in delocalization is part of the reason for the change in color. The $\mathrm{p}K_{In}$ of phenolphthalein is 9.4, and so the end point occurs in slightly basic solution. Litmus, another common indicator, has $\mathrm{p}K_{In} = 6.5$; it is red for $\mathrm{pH} < 5$ and blue for $\mathrm{pH} > 8$.



4

There are many naturally occurring indicators. For instance, a single compound is responsible for the colors of red poppies and blue cornflowers: the pH of the sap is different in the two plants. The color of hydrangeas also depends on the acidity of their sap and can be controlled by modifying the acidity of the soil (Fig. 12.11).

The *end point* is a property of the indicator; the *stoichiometric point* is a property of the chemical reaction taking place during the titration. It is important to select an indicator with an end point close to the stoichiometric point of the titration (Fig. 12.12). In practice, the $\mathrm{p}K_{In}$ of the indicator should be within about 1 pH unit of the stoichiometric point:

$$\mathrm{p}K_{In} \approx \mathrm{pH(at\ the\ stoichiometric\ point)} \pm 1$$

FIGURE 12.11 The color of these hydrangeas depends on the acidity of the soil in which they are growing: acid soil results in blue flowers, alkaline soil results in pink flowers.

Lab Video 12.11

Phenolphthalein can be used for titrations with a stoichiometric point near pH = 9, such as a titration of a weak acid with a strong base. Methyl orange changes color between pH = 3.2 and pH = 4.4 and can be used in the titration of a weak base with a strong acid. Ideally, indicators for strong acid–strong base titrations should have end points close to pH = 7; however, in strong acid–strong base titrations, the pH changes rapidly over several pH units, and even phenolphthalein can be used. Table 12.3 includes the pH ranges over which several indicators can be used.

Acid–base indicators are weak acids that change color close to pH = pK_{In}; an indicator should be chosen so that its end point is close to the stoichiometric point of the titration.

12.7 Stoichiometry of Polyprotic Acid Titrations

Because many biological systems use polyprotic acids and their anions to control pH, we need to be familiar with pH curves for polyprotic titrations and to be able to calculate the pH during such a titration. The titration of a polyprotic acid proceeds in the same way as that of a monoprotic acid, but there are as many stoichiometric points in the titration as there are acidic hydrogen atoms. We therefore have to keep track of the major species in solution at each stage, as described in Sections 11.16 and 11.17 and summarized in Figs. 11.21 and 11.22.

Suppose we are titrating the triprotic acid H_3PO_4 with a solution of NaOH. The experimentally determined pH curve is shown in Fig. 12.13. Notice that there are three stoichiometric points (B, D, and F) and three buffer regions (A, C, and E). In pH calculations for these systems, we assume that, as we add the hydroxide solution, initially NaOH reacts completely with the acid to form the diprotic conjugate base $H_2PO_4^-$:

$$H_3PO_4(aq) + OH^-(aq) \longrightarrow H_2PO_4^-(aq) + H_2O(l) \qquad \textbf{(B)}$$

At point A, the system is in the first buffer region and pH = pK_{a1}. The pH in the first buffer region is determined by the proton transfer equilibrium between H_3PO_4 molecules and $H_2PO_4^-$ ions produced in the titration.

Once all the acid H_3PO_4 molecules have lost their first acidic protons, the system is at B and the primary species in solution are $H_2PO_4^-$ and sodium ions. Point B is the first stoichiometric point, and to reach it we need to supply 1 mol NaOH for each mole of H_3PO_4.

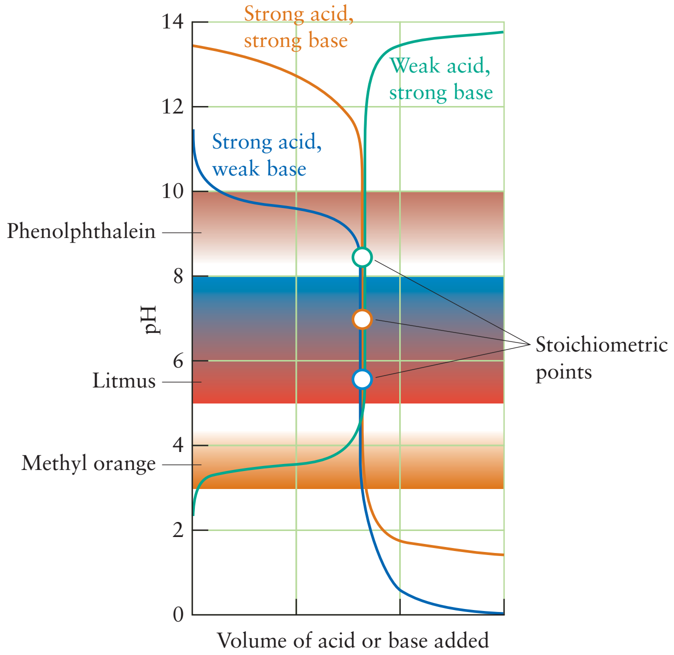


FIGURE 12.12 Ideally, an indicator should have a sharp color change close to the stoichiometric point of the titration, which is at pH = 7 for a strong acid–strong base titration. However, the change in pH is so abrupt that phenolphthalein can be used. Phenolphthalein can also be used to detect the stoichiometric point of a weak acid–strong base titration, but methyl orange can not. However, methyl orange can be used for a weak base–strong acid titration. Phenolphthalein would be inappropriate in this case, because its color change occurs well away from the stoichiometric point.

Lab Video 12.12

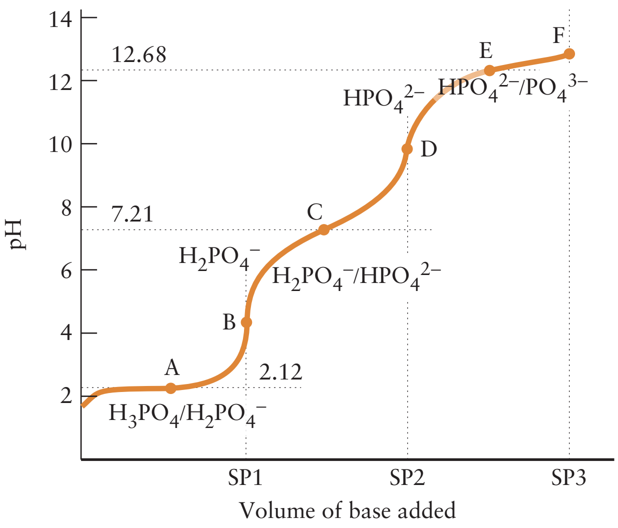

FIGURE 12.13 The variation of the pH of the analyte solution during the titration of a triprotic acid (phosphoric acid). The major species present in solution at the first two stoichiometric points (B and D) and at points when half the titrant required to reach a stoichiometric point has been added (A, C, and E) are shown. Compare this diagram with Fig. 11.22. The labels SP1, SP2, and SP3 denote the volumes of base required to reach the three stoichiometric points. Points A through F are explained in the text.

As we continue to add base, it reacts with the $H_2PO_4^-$ to form that acid's conjugate base, HPO_4^{2-}:

$$H_2PO_4^-(aq) + OH^-(aq) \longrightarrow HPO_4^{2-}(aq) + H_2O(l) \qquad \textbf{(C)}$$

At point C, the system is in the second buffer region and pH = pK_{a2}. Further base takes us to the second stoichiometric point, D. The primary species in solution are now HPO_4^{2-} and sodium ions, which form a solution of $Na_2HPO_4(aq)$. To reach the second stoichiometric point, an additional mole of NaOH is required for each mole of H_3PO_4 originally present. A total of 2 mol NaOH for each mole of H_3PO_4 has now been added.

Additional base reacts with HPO_4^{2-} to produce PO_4^{3-}:

$$HPO_4^{2-}(aq) + OH^-(aq) \longrightarrow PO_4^{3-}(aq) + H_2O(l) \qquad \textbf{(D)}$$

At point E, the system is in the third buffer region and pH = pK_{a3}. When this reaction is complete, the primary species in solution are PO_4^{3-} ions and sodium ions. To reach this stoichiometric point (F in the plot), we have to add another mole of OH^- for each mole of H_3PO_4 initially present. At this point, a total of 3 mol OH^- has been added for each mole of H_3PO_4. Notice that the third stoichiometric point (point F) is indistinct, largely because K_{a3} is comparable to K_w. As a result, it is not detected in titrations.

Figure 12.14 shows the pH curve of a diprotic acid, such as oxalic acid, $H_2C_2O_4$. There are two stoichiometric points (B and D) and two buffer regions (A and C). The major species present in solution at each point are indicated. Note that it takes twice as much base to reach the second stoichiometric point as it does to reach the first.

Self-Test 12.8A What volume of 0.010 M NaOH(aq) is required to reach (a) the first stoichiometric point and (b) the second stoichiometric point in a titration of 25.00 mL of 0.010 M H_2SO_3(aq)?

[***Answer:*** (a) 25 mL; (b) 50. mL]

Self-Test 12.8B What volume of 0.020 M NaOH(aq) is required to reach (a) the first stoichiometric point and (b) the second stoichiometric point in a titration of 30.00 mL of 0.010 M H_3PO_4(aq)?

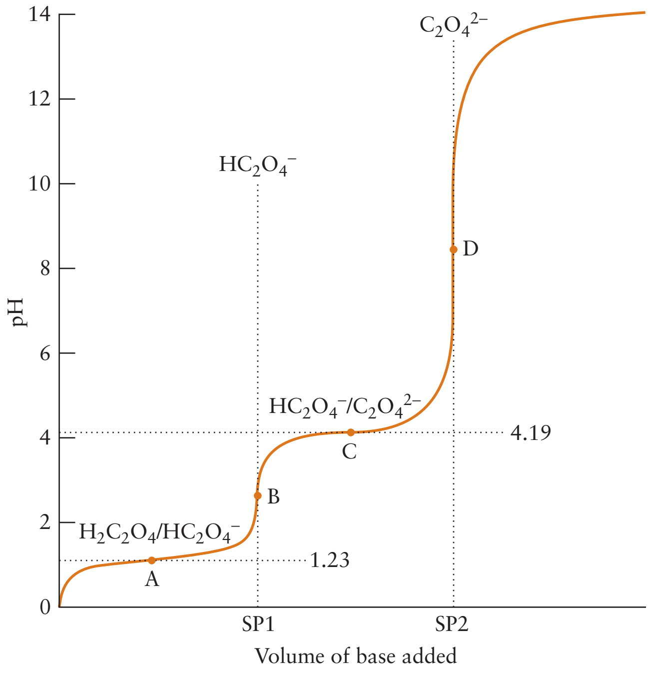

FIGURE 12.14 The variation of the pH of the analyte solution during the titration of a diprotic acid (oxalic acid) and the major species present in solution at the two stoichiometric points (B and D) and at points when half the titrant required to reach a stoichiometric point has been added (A and C). Compare this diagram with Fig. 11.21. The labels SP1 and SP2 denote the volumes of base required to reach the two stoichiometric points.

We can predict the pH at any point in the titration of a polyprotic acid with a strong base by using the reaction stoichiometry to recognize what stage we have reached in the titration. We then identify the principal solute species at that point and the principal proton transfer equilibrium that determines the pH.

Self-Test 12.9A A sample of 0.200 M $H_3PO_4(aq)$ of volume 25.0 mL was titrated with 0.100 M NaOH(aq). Identify the primary species in solution after the addition of the following volumes of NaOH solution: (a) 70.0 mL; (b) 100.0 mL.

[***Answer:*** (a) Between first and second stoichiometric points, Na^+ from the base, $H_2PO_4^-$, and HPO_4^{2-}; (b) at the second stoichiometric point, Na^+ and HPO_4^{2-}.]

Self-Test 12.9B A sample of 0.100 M $H_2S(aq)$ of volume 20.0 mL was titrated with 0.300 M NaOH(aq). Identify the primary species in solution after the addition of the following volumes of NaOH solution: (a) 5.0 mL; (b) 13.4 mL.

The titration of a polyprotic acid has a stoichiometric point corresponding to the removal of each acidic hydrogen atom. The pH of a solution of a polyprotic acid undergoing a titration is estimated by considering the primary species in solution and the proton transfer equilibrium that determines the pH.

SOLUBILITY EQUILIBRIA

Up to this point, we have focused on aqueous equilibria involving proton transfer. Now we apply the same principles to the equilibrium that exists between a solid salt and its dissolved ions in a saturated solution. We can use the equilibrium constant for the dissolution of a substance to predict the solubility of a salt and to control precipitate formation. These methods are used in the laboratory to separate and analyze mixtures of salts. They also have important practical applications in municipal wastewater treatment, the extraction of minerals from seawater, the formation and loss of bones and teeth, and the global carbon cycle.

12.8 The Solubility Product

The equilibrium constant for the solubility equilibrium between an ionic solid and its dissolved ions is called the **solubility product,** K_{sp}, of the solute. For example, the solubility product for bismuth sulfide, Bi_2S_3, is defined as

K_{sp} is also called the *solubility product constant* and, most simply, the *solubility constant*.

$$Bi_2S_3(s) \rightleftharpoons 2\ Bi^{3+}(aq) + 3\ S^{2-}(aq) \qquad K_{sp} = (a_{Bi^{3+}})^2(a_{S^{2-}})^3$$

Because the concentrations of ions in a solution of a sparingly soluble salt are low, we assume, just as we did for solutions of weak acids and bases (Section 11.7), that we can approximate K_{sp} by using molar concentrations:

$$K_{sp} = [Bi^{3+}]^2[S^{2-}]^3$$

Solid Bi_2S_3 does not appear in the expression for K_{sp}, because it is a pure solid and its activity is 1 (Section 10.2). A solubility product is used in the same way as any other equilibrium constant. However, because ion–ion interactions, even in dilute electrolyte solutions, can complicate its interpretation, a solubility product is generally meaningful only for sparingly soluble salts. Another complication that arises when dealing with nearly insoluble compounds is that dissociation of the ions is rarely complete, and a saturated solution of PbI_2, for instance, contains substantial concentrations of $Pb^{2+}I^-$ and $Pb^{2+}(I^-)_2$ ion clusters. At best, the calculations that we are about to describe are only estimates.

One of the simplest ways to determine K_{sp} is to measure the molar solubility of the compound, the molar concentration of the compound in a saturated solution, but more advanced and accurate methods are also available. Table 12.4 gives some experimental values. In the following calculations, we use s to denote the numerical value of the molar solubility expressed in moles per liter; for example, if the molar solubility of a compound is 65 μmol·L^{-1} (that is, 6.5×10^{-5} mol·L^{-1}), then we write $s = 6.5 \times 10^{-5}$.

Electrochemical methods for determining solubility products are discussed in section 13.8.

TABLE 12.4 Solubility Products at 25°C

Compound	Formula	K_{sp}	Compound	Formula	K_{sp}
aluminum hydroxide	$Al(OH)_3$	1.0×10^{-33}	lead(II) fluoride	PbF_2	3.7×10^{-8}
antimony sulfide	Sb_2S_3	1.7×10^{-93}	iodate	$Pb(IO_3)_2$	2.6×10^{-13}
barium carbonate	$BaCO_3$	8.1×10^{-9}	iodide	PbI_2	1.4×10^{-8}
fluoride	BaF_2	1.7×10^{-6}	sulfate	$PbSO_4$	1.6×10^{-8}
sulfate	$BaSO_4$	1.1×10^{-10}	sulfide	PbS	8.8×10^{-29}
bismuth sulfide	Bi_2S_3	1.0×10^{-97}	magnesium ammonium phosphate	$MgNH_4PO_4$	2.5×10^{-13}
calcium carbonate	$CaCO_3$	8.7×10^{-9}	carbonate	$MgCO_3$	1.0×10^{-5}
fluoride	CaF_2	4.0×10^{-11}	fluoride	MgF_2	6.4×10^{-9}
hydroxide	$Ca(OH)_2$	5.5×10^{-6}	hydroxide	$Mg(OH)_2$	1.1×10^{-11}
sulfate	$CaSO_4$	2.4×10^{-5}	mercury(I) chloride	Hg_2Cl_2	2.6×10^{-18}
chromium(III) iodate	$Cr(IO_3)_3$	5.0×10^{-6}	iodide	Hg_2I_2	1.2×10^{-28}
copper(I) bromide	$CuBr$	4.2×10^{-8}	mercury(II) sulfide, black	HgS	1.6×10^{-52}
chloride	$CuCl$	1.0×10^{-6}	sulfide, red	HgS	1.4×10^{-53}
iodide	CuI	5.1×10^{-12}	nickel(II) hydroxide	$Ni(OH)_2$	6.5×10^{-18}
sulfide	Cu_2S	2.0×10^{-47}	silver bromide	$AgBr$	7.7×10^{-13}
copper(II) iodate	$Cu(IO_3)_2$	1.4×10^{-7}	carbonate	Ag_2CO_3	6.2×10^{-12}
oxalate	CuC_2O_4	2.9×10^{-8}	chloride	$AgCl$	1.6×10^{-10}
sulfide	CuS	1.3×10^{-36}	hydroxide	$AgOH$	1.5×10^{-8}
iron(II) hydroxide	$Fe(OH)_2$	1.6×10^{-14}	iodide	AgI	8×10^{-17}
sulfide	FeS	6.3×10^{-18}	sulfide	Ag_2S	6.3×10^{-51}
iron(III) hydroxide	$Fe(OH)_3$	2.0×10^{-39}	zinc hydroxide	$Zn(OH)_2$	2.0×10^{-17}
lead(II) bromide	$PbBr_2$	7.9×10^{-5}	sulfide	ZnS	1.6×10^{-24}
chloride	$PbCl_2$	1.6×10^{-5}			

EXAMPLE 12.7 **Determining the solubility product**

The molar solubility of silver chromate, Ag_2CrO_4, is 65 μmol·L^{-1} at 25°C. Determine the value of K_{sp} for silver chromate at 25°C.

Anticipate Because the molar solubility is low, we should expect K_{sp} to be a very small number.

PLAN First, we write the chemical equation for the equilibrium and the expression for the solubility product. To evaluate K_{sp}, we need to know the molarity of each type of ion formed by the salt. We determine the molarities from the molar solubility and the stoichiometric relations between the species.

What should we assume? That the salt dissociates completely in water and that the anion is not protonated by water.

SOLVE

Write the chemical equation.

$$Ag_2CrO_4(s) \rightleftharpoons 2\,Ag^+(aq) + CrO_4^{2-}(aq)$$

Write the expression for the solubility product.

$$K_{sp} = [Ag^+]^2[CrO_4^{2-}]$$

From 2 mol $Ag^+ \simeq$ 1 mol Ag_2CrO_4 and 65 μmol·L^{-1} = 6.5×10^{-5} mol·L^{-1},

$$[Ag^+] = 2s = 2 \times (6.5 \times 10^{-5})$$

From 1 mol $CrO_4^{2-} \simeq$ 1 mol Ag_2CrO_4,

$$[CrO_4^{2-}] = s = 6.5 \times 10^{-5}$$

From $K_{sp} = [Ag^+]^2[CrO_4^{2-}] = (2s)^2(s) = 4s^3$,

$$K_{sp} = 4 \times (6.5 \times 10^{-5})^3 = 1.1 \times 10^{-12}$$

Evaluate As expected, K_{sp} is very small.

Self-Test 12.10A The molar solubility of lead(II) iodate, $Pb(IO_3)_2$, at 25°C is 40. μmol·L^{-1}. What is the value of K_{sp} for lead(II) iodate?

[***Answer:*** 2.6×10^{-13}]

Self-Test 12.10B The molar solubility of silver bromide, AgBr, at 25°C is 0.88 μmol·L^{-1}. What is the value of K_{sp} for silver bromide?

EXAMPLE 12.8 **Estimating the molar solubility from the solubility product**

According to Table 12.4, $K_{sp} = 5.0 \times 10^{-6}$ for chromium(III) iodate in water at 25°C. Estimate the molar solubility of the compound at 25°C.

PLAN Set up the solubility product in terms of the molar solubility, taking into account the stoichiometric relations as given by the chemical equation for the equilibrium, then solve for the molar solubility.

What should we assume? That the salt dissociates completely in water and that the anion is not protonated by water.

SOLVE Assume complete dissociation.

Write the chemical equation.

$$Cr(IO_3)_3(s) \rightleftharpoons Cr^{3+}(aq) + 3\,IO_3^-(aq)$$

Write the expression for the solubility product.

$$K_{sp} = [Cr^{3+}][IO_3^-]^3$$

From 1 mol $Cr^{3+} \simeq$ 1 mol $Cr(IO_3)_3$,

$$[Cr^{3+}] = s$$

From 3 mol $IO_3^- \simeq$ 1 mol $Cr(IO_3)_3$,

$$[IO_3^-] = 3s$$

Write the expression for K_{sp} in terms of s.

$$K_{sp} = [Cr^{3+}][IO_3^-]^3 = s \times (3s)^3 = 27s^4$$

From $s = (K_{sp}/27)^{1/4}$,

$$s = \{(5.0 \times 10^{-6})/27\}^{1/4} = 0.021$$

A note on good practice: A quick way to evaluate the fourth root is to take the square root twice in succession.

The molar solubility of $Cr(IO_3)_3$ is therefore 0.021 mol·L^{-1}.

Self-Test 12.11A The solubility product of silver sulfate, Ag_2SO_4, is 1.4×10^{-5}. Estimate the molar solubility of the salt.

[***Answer:*** 15 mmol·L^{-1}]

Self-Test 12.11B The solubility product of lead(II) fluoride, PbF_2, is 3.7×10^{-8}. Estimate the molar solubility of the salt.

The solubility product is the equilibrium constant for the equilibrium between an undissolved salt and its ions in a saturated solution.

12.9 The Common-Ion Effect

Sometimes we have to precipitate one ion of a sparingly soluble salt. For example, heavy metal ions such as lead and mercury can be removed from municipal wastewater by precipitating them as the hydroxides. However, because the ions are in dynamic equilibrium with the solid salt, some heavy metal ions remain in solution. How can we remove more of the ions?

We can use Le Chatelier's principle as a guide. This principle tells us that, if we add a second salt or an acid that supplies one of the same ions—a "common ion"—to a saturated solution of a salt, then the equilibrium will tend to adjust by decreasing

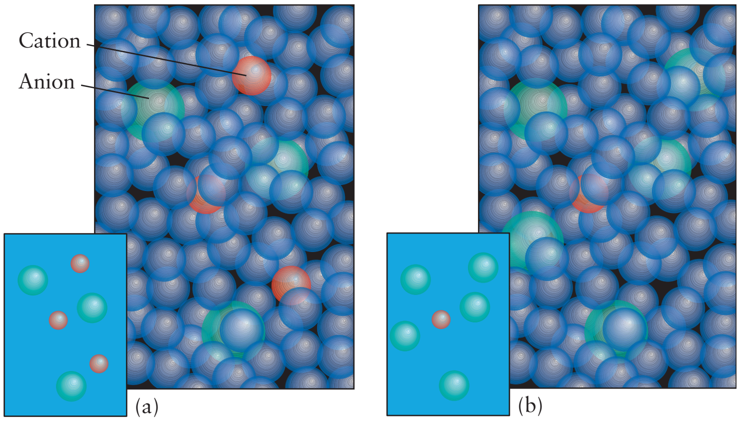

FIGURE 12.15 If the concentration of one of the ions of a slightly soluble salt is increased, the concentration of the other decreases to maintain a constant value of K_{sp}. (a) The cations (pink) and anions (green) in solution. (b) When more anions are added (together with their accompanying spectator ions, which are not shown), the concentration of cations decreases. In other words, the solubility of the original compound is reduced by the presence of a common ion. In the insets, the blue background represents the solvent (water).

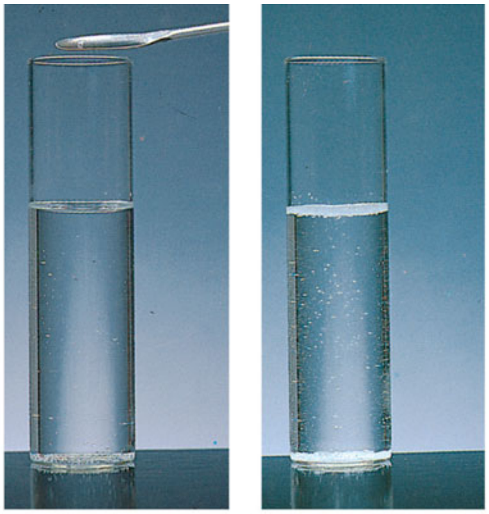
FIGURE 12.16 (a) A saturated solution of zinc acetate in water. (b) When additional acetate ions are added (as a single crystal of solid sodium acetate in the spatula shown in part (a), the solubility of the zinc acetate is significantly reduced and more zinc acetate precipitates.



(a) (b)

the concentration of the added ions (Fig. 12.15). That is, the solubility of the original salt is decreased, and it precipitates. We can conclude that the addition of excess OH^- ions to the water supply should precipitate more of the heavy metal ions as their hydroxides. In other words, the addition of OH^- ions reduces the solubility of the heavy metal hydroxide. The decrease in solubility caused by the addition of a common ion is called the **common-ion effect.**

We can gain a quantitative understanding of the common-ion effect by considering how a change in the concentration of one of the ions affects the solubility product. Suppose we have a saturated solution of silver chloride in water:

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = [Ag^+][Cl^-]$$

Experimentally, $K_{sp} = 1.6 \times 10^{-10}$ at 25°C, and the molar solubility of AgCl in water is 13 $\mu mol \cdot L^{-1}$. If we add sodium chloride to the solution, the concentration of Cl^- ions increases. For the equilibrium constant to remain constant, the concentration of Ag^+ ions must decrease. Because there is now less Ag^+ in solution, the solubility of AgCl is lower in a solution of NaCl than it is in pure water. A similar effect occurs whenever two salts having a common ion are mixed (Fig. 12.16).

The prediction of the numerical value of the common-ion effect is difficult. Because ions interact with one another strongly, simple equilibrium calculations are rarely valid: the activities of ions can differ markedly from their molarities. However, we can still get an idea of the size of the common-ion effect by solving the K_{sp} expression for the concentration of the ion other than the common ion.

Thinking point: Could the addition of a salt *without* a common ion affect the solubility of a sparingly soluble salt?

EXAMPLE 12.9 Estimating the effect of a common ion on solubility

Estimate the solubility of silver chloride in 1.0×10^{-4} M NaCl(aq) at 25°C.

Anticipate Due to the presence of a common ion, we should expect the solubility of AgCl in NaCl(aq) to be lower than in pure water.

PLAN Set up the solubility product and solve for the concentration of silver ions.

What should we assume? That the concentration of chloride ions from the AgCl is insignificant compared to the concentration of the chloride ions in the sodium chloride solution.

SOLVE For a given concentration of Cl^- ions, the concentration of Ag^+ ions must satisfy K_{sp}.

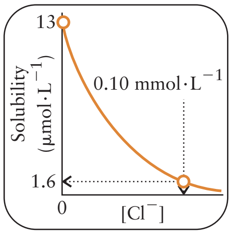
From $K_{sp} = [Ag^+][Cl^-]$,

$$[Ag^+] = \frac{K_{sp}}{[Cl^-]}$$

It follows that silver chloride will dissolve in 1.0×10^{-4} M NaCl(aq), in which $[Cl^-] = 1.0 \times 10^{-4}\ mol{\cdot}L^{-1}$, until the concentration of Ag^+ ions is given by:

With $[Cl^-] = 1.0 \times 10^{-4}\ mol{\cdot}L^{-1}$ and $K_{sp} = 1.6 \times 10^{-10}$,

$$[Ag^+] = \frac{1.6 \times 10^{-10}}{1.0 \times 10^{-4}} = 1.6 \times 10^{-6}$$



Evaluate The concentration of Ag^+ ions, and hence the solubility of AgCl formula units, is 1.6 $\mu mol{\cdot}L^{-1}$, which is about 10 times less than the solubility of AgCl in pure water, as expected.

Self-Test 12.12A What is the approximate molar solubility of calcium carbonate in 0.20 M $CaCl_2$(aq)?

[***Answer:*** 44 $nmol{\cdot}L^{-1}$]

Self-Test 12.12B What is the approximate molar solubility of silver bromide in 0.10 M $CaBr_2$(aq)?

The common-ion effect is the reduction in solubility of a sparingly soluble salt by the addition of a soluble salt that has an ion in common with it.

12.10 Predicting Precipitation

Sometimes it is important to know under what conditions a precipitate will form. For example, if we are analyzing a mixture of ions, we may want to precipitate only one type of ion to separate it from the mixture. In Section 10.5, we saw how to predict the direction in which a reaction will take place by comparing the values of Q, the reaction quotient, and K, the equilibrium constant. Exactly the same techniques can be used to decide whether a precipitate is likely to form when two electrolyte solutions are mixed. In this case, the equilibrium constant is the solubility product, K_{sp}, and the reaction quotient is denoted Q_{sp}. When the concentrations of the ions are high, Q_{sp} is greater than K_{sp}, precipitation occurs, and the value of Q_{sp} drops to equal K_{sp} (Fig. 12.17).

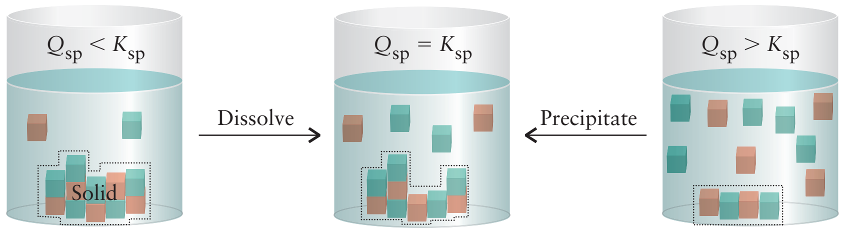


FIGURE 12.17 The relative magnitudes of the solubility quotient, Q_{sp}, and the solubility product, K_{sp}, are used to decide whether a salt will dissolve (left) or precipitate (right). When the concentrations of the ions in solution are low (left) Q_{sp} is smaller than K_{sp}; when the ion concentrations are high (right), Q_{sp} is larger than K_{sp}.

EXAMPLE 12.10 **Predicting whether a precipitate will form when two solutions are mixed**

Suppose we mix equal volumes of 0.2 M $Pb(NO_3)_2(aq)$ and KI(aq) at 25°C. Will lead(II) iodide precipitate?

Anticipate Because the concentrations of the Pb^{2+} and I^- ions are high and the solubility product of PbI_2 is low, we should expect precipitation to occur.

PLAN First calculate the new values of the ions in the mixed solution, before reaction occurs. In this case, because equal volumes are mixed together, the new volume is twice each initial volume, and so the new molarities are half their original values.

What should we assume? That the lead(II) iodide is fully dissociated in aqueous solution.

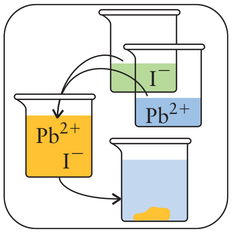
SOLVE We know from Table 12.4 that $K_{sp} = 1.4 \times 10^{-8}$ for PbI_2 at 25°C.

Write the chemical equation and its equilibrium constant.

$$PbI_2(s) \rightleftharpoons Pb^{2+}(aq) + 2\,I^-(aq), \qquad K_{sp} = [Pb^{2+}][I^-]^2$$

Calculate the new molarities of the ions.

$$Pb^{2+}(aq)\text{: } (0.2\text{ mol·L}^{-1})/2 = 0.1\text{ mol·L}^{-1}$$
$$I^-(aq)\text{: } (0.2\text{ mol·L}^{-1})/2 = 0.1\text{ mol·L}^{-1}$$



From $Q_{sp} = [Pb^{2+}][I^-]^2$,

$$Q_{sp} = 0.1 \times (0.1)^2 = 1 \times 10^{-3}$$

Evaluate The value of Q_{sp} is considerably higher than K_{sp}, and so, as predicted, a precipitate forms (Fig. 12.18).

FIGURE 12.18 When a few drops of lead(II) nitrate solution are added to a solution of potassium iodide, yellow lead(II) iodide immediately precipitates.

Lab Video 12.18

Self-Test 12.13A Does a precipitate of silver chloride form when 200. mL of 1.0×10^{-4} M $AgNO_3(aq)$ and 900. mL of 1.0×10^{-6} M KCl(aq) are mixed? Assume complete dissociation.

[***Answer:*** No ($Q_{sp} = 1.5 \times 10^{-11}$; $Q_{sp} < K_{sp}$)]

Self-Test 12.13B Does a precipitate of barium fluoride form when 100. mL of 1.0×10^{-3} M $Ba(NO_3)_2(aq)$ is mixed with 200. mL of 1.0×10^{-3} M KF(aq)? Ignore possible protonation of F^-.

A salt precipitates if Q_{sp} is greater than K_{sp}.

12.11 Selective Precipitation

It is sometimes possible to separate different cations from a solution by adding a soluble salt containing an anion with which they form salts with very different solubilities. For example, seawater is a mixture of many different ions. It is possible to precipitate magnesium ions from seawater by adding hydroxide ions. However, other cations are also present in seawater. Their individual concentrations and the relative solubilities of their hydroxides determine which will precipitate first if a certain amount of hydroxide is added. Optimum separation of two compounds is achieved when Q_{sp} for one species exceeds its K_{sp} but Q_{sp} for the second species is significantly less than its K_{sp}. Example 12.11 illustrates a strategy for predicting the order of precipitation.

EXAMPLE 12.11 Predicting the order of precipitation

A sample of seawater contains, among other solutes, the following concentrations of soluble cations: 0.050 mol·L^{-1} $Mg^{2+}(aq)$ and 0.010 mol·L^{-1} $Ca^{2+}(aq)$. (a) Use the information in Table 12.4 to determine the order in which each ion precipitates as solid NaOH is added, and give the concentration of OH^- when precipitation of each begins. Assume no volume change on addition of the NaOH and that the temperature is 25°C. (b) If the first compound to precipitate is $X(OH)_2$, calculate the concentration of X^{2+} ions remaining in solution when the second ion precipitates.

Anticipate In (a), because $K_{sp}(Mg(OH)_2)$ is so much smaller than $K_{sp}(Ca(OH)_2)$, and the formulas similar, we should expect that $Mg(OH)_2$ will precipitate first. In (b), because much of X^{2+} has precipitated as $X(OH)_2$ and is no longer in solution, we should expect its concentration to be very small when the second ion precipitates.

PLAN A salt begins to precipitate when the concentrations of its ions are such that $Q_{sp} > K_{sp}$. (a) Calculate the value of $[OH^-]$ required for each salt to precipitate by writing the expression for K_{sp} for each salt and then substituting the data provided. (b) Calculate the remaining concentration of the first cation to precipitate by substituting the value of $[OH^-]$ into K_{sp} for that hydroxide.

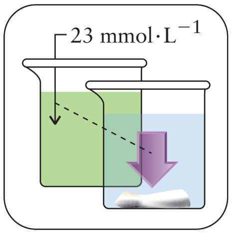
SOLVE (a) Write the chemical equation and K_{sp} for the dissolving of $Ca(OH)_2$:

$$Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\,OH^-(aq) \qquad K_{sp} = [Ca^{2+}][OH^-]^2$$

and from Table 12.4, $K_{sp} = 5.5 \times 10^{-6}$. Then:

Find $[OH^-]$ from $K_{sp} = [Ca^{2+}][OH^-]^2$ in the form $[OH^-] = \{K_{sp}/[Ca^{2+}]\}^{1/2}$.

$$[OH^-] = \left(\frac{5.5 \times 10^{-6}}{0.010}\right)^{1/2} = 0.023$$



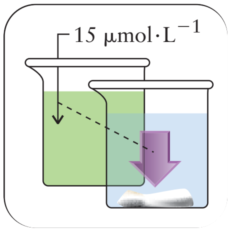
Write the chemical equation and K_{sp} for the dissolving of $Mg(OH)_2$:

$$Mg(OH)_2(s) \rightleftharpoons Mg^{2+}(aq) + 2\,OH^-(aq) \qquad K_{sp} = [Mg^{2+}][OH^-]^2$$

From Table 12.4, $K_{sp} = 1.1 \times 10^{-11}$.

Find $[OH^-]$ from $K_{sp} = [Mg^{2+}][OH^-]^2$ in the form $[OH^-] = \{K_{sp}/[Mg^{2+}]\}^{1/2}$.

$$[OH^-] = \left(\frac{1.1 \times 10^{-11}}{0.050}\right)^{1/2} = 1.5 \times 10^{-5}$$



Evaluate We conclude that the hydroxides precipitate in the order $Mg(OH)_2$ at 1.5×10^{-5} mol·L^{-1} $OH^-(aq)$ and $Ca(OH)_2$ at 0.023 mol·L^{-1} $OH^-(aq)$.

(b) Find the concentration of magnesium ions when $[OH^-] = 0.023$:

Find $[Mg^{2+}]$ from $K_{sp} = [Mg^{2+}][OH^-]^2$ in the form $[Mg^{2+}] = K_{sp}/[OH^-]^2$.

$$[Mg^{2+}] = \frac{1.1 \times 10^{-11}}{(0.023)^2} = 2.1 \times 10^{-8}$$

Evaluate The concentration of magnesium ions remaining when $Ca(OH)_2$ begins to precipitate is indeed very small.

Self-Test 12.14A Potassium carbonate is added to a solution containing the following concentrations of cations: 0.030 $mol \cdot L^{-1}$ $Mg^{2+}(aq)$ and 0.0010 $mol \cdot L^{-1}$ $Ca^{2+}(aq)$. (a) Use the information in Table 12.4 to determine the order in which each ion precipitates as the concentration of K_2CO_3 is increased and give the concentration of CO_3^{2-} when precipitation of each begins. (b) Calculate the concentration of the first ion to precipitate that remains in solution when the second ion precipitates.

[*Answer:* (a) $CaCO_3$ precipitates first, at 8.7 $\mu mol \cdot L^{-1}$ CO_3^{2-}, then $MgCO_3$ at 0.33 $mmol \cdot L^{-1}$ CO_3^{2-}; (b) 26 $\mu mol \cdot L^{-1}$ Ca^{2+}]

Self-Test 12.14B Chloride ion is added to a solution containing the following concentrations of soluble salts: 0.020 $mol \cdot L^{-1}$ $Pb(NO_3)_2(aq)$ and 0.0010 $mol \cdot L^{-1}$ $AgNO_3(aq)$. (a) Use the information in Table 12.4 to determine the order in which each ion precipitates as the concentration of chloride ion is increased and give the concentration of Cl^- when precipitation of each begins. (b) Calculate the concentration of the first ion to precipitate that remains in solution when the second ion precipitates.

A mixture of ions in solution can be separated by adding an oppositely charged ion with which they form salts having very different solubilities.

12.12 Dissolving Precipitates

When a precipitate has been formed during the qualitative analysis of the ions present in a solution, it may be necessary to dissolve the precipitate again to identify the cation or anion. One strategy is to remove one of the ions from the solubility equilibrium so that the precipitate will continue to dissolve in a fruitless chase for equilibrium. Suppose, for example, that a solid hydroxide such as iron(III) hydroxide is in equilibrium with its ions in solution:

$$Fe(OH)_3(s) \rightleftharpoons Fe^{3+}(aq) + 3\ OH^-(aq)$$

To dissolve more of the solid, we can add acid. The H_3O^+ ions from the acid remove the OH^- ions by converting them into water, and the $Fe(OH)_3$ dissolves.

Many carbonate, sulfite, and sulfide precipitates can be dissolved by the addition of acid, because the anions react with the acid to form a gas that bubbles out of solution. For example, in a saturated solution of zinc carbonate, solid $ZnCO_3$ is in equilibrium with its ions:

$$ZnCO_3(s) \rightleftharpoons Zn^{2+}(aq) + CO_3^{2-}(aq)$$

The CO_3^{2-} ions react with acid to form CO_2:

$$CO_3^{2-}(aq) + 2\ HNO_3(aq) \longrightarrow CO_2(g) + H_2O(l) + 2\ NO_3^-(aq)$$

The dissolution of carbonates by acid is an undesired result of acid rain, which has damaged the appearance of many historic marble and limestone monuments (Fig. 12.19; marble and limestone are forms of calcium carbonate).

(a)

(b)

FIGURE 12.19 The state of the carving on Cleopatra's Needle has deteriorated as a result of the action of acid rain: (a) after 3500 years in the Egyptian desert; (b) after a further 90 years in Central Park, New York City.

An alternative procedure for removing an ion from solution is to change its identity by changing its oxidation state. The metal ions in very insoluble heavy metal sulfide precipitates can be dissolved by oxidizing the sulfide ion to elemental sulfur. For example, copper(II) sulfide, CuS, takes part in the equilibrium

$$CuS(s) \rightleftharpoons Cu^{2+}(aq) + S^{2-}(aq)$$

However, when nitric acid is added, the sulfide ions are oxidized to elemental sulfur:

$$3\ S^{2-}(aq) + 8\ HNO_3(aq) \longrightarrow 3\ S(s) + 2\ NO(g) + 4\ H_2O(l) + 6\ NO_3^-(aq)$$

This complicated oxidation removes the sulfide ions from the equilibrium, and Cu^{2+} ions dissolve as $Cu(NO_3)_2$.

Some precipitates dissolve when the temperature is changed. This strategy is used to purify precipitates. The mixture is heated to dissolve the solid and filtered to remove insoluble impurities. The solid is then allowed to re-form as the solution cools and is removed from the solution in a second filtration. Complex ion formation (Section 12.13) can also be used to dissolve metal ions.

The solubility of a solid can be increased by removing one of its ions from solution; acid can be used to dissolve a hydroxide, sulfide, sulfite, or carbonate precipitate; and nitric acid can be used to oxidize metal sulfides to sulfur and a soluble salt. Some solids can be dissolved by changing the temperature.

12.13 Complex Ion Formation

The solubility of a salt can be increased by finding a way to hide away the ions in solution, because then the dissolution process continues in a vain attempt to reach equilibrium. To remove an ion, we can use the fact that many metal cations are Lewis acids (Section 11.2). When a Lewis acid and a Lewis base react, they form a coordinate covalent bond and the product is called a **coordination complex.** In this section, we consider complexes in which the Lewis acid is a metal cation, such as Ag^+. An example is the formation of $Ag(NH_3)_2{}^+$ when an aqueous solution of the Lewis base ammonia is added to a solution of silver ions:

$$Ag^+(aq) + 2\,NH_3(aq) \longrightarrow Ag(NH_3)_2{}^+(aq)$$

If enough ammonia is added to a precipitate of silver halide, all the precipitate dissolves. A similar procedure is used to remove the silver halide emulsion from an exposed photographic film after it has been developed. In this case, the reagent used to form the complex is the thiosulfate ion, $S_2O_3{}^{2-}$:

$$Ag^+(aq) + 2\,S_2O_3{}^{2-}(aq) \longrightarrow Ag(S_2O_3)_2{}^{3-}(aq)$$

Complex formation removes some of the Ag^+ ions from solution. As a result, to preserve the value of K_{sp}, more silver chloride dissolves. Formation of a complex increases the solubility of a sparingly soluble compound.

To treat complex formation quantitatively, we note that complex formation and the dissolving of the salt are both at equilibrium; so we can write

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = [Ag^+][Cl^-] \qquad \textbf{(E)}$$

$$Ag^+(aq) + 2\,NH_3(aq) \rightleftharpoons Ag(NH_3)_2{}^+(aq) \qquad K_f = \frac{[Ag(NH_3)_2{}^+]}{[Ag^+][NH_3]^2} \qquad \textbf{(F)}$$

The equilibrium constant for the formation of a complex ion is called the **formation constant,** K_f. At 25°C, $K_f = 1.6 \times 10^7$ for reaction F. Values for some other complexes are given in Table 12.5, and Example 12.12 shows how to use them.

EXAMPLE 12.12 Calculating molar solubility in the presence of complex formation

Calculate the molar solubility of silver chloride in 0.10 M $NH_3(aq)$, given that $K_{sp} = 1.6 \times 10^{-10}$ for silver chloride and $K_f = 1.6 \times 10^7$ for the ammonia complex of Ag^+ ions, $Ag(NH_3)_2{}^+$.

Anticipate Because silver ions form a complex with ammonia, we should expect that the solubility of silver chloride will be greater in the ammonia solution than in water.

What should we assume? That the reaction of ammonia with water does not significantly affect this equilibrium.

TABLE 12.5 Formation Constants of Complexes in Water at 25°C

Equilibrium	K_f
$Ag^+(aq) + 2\,CN^-(aq) \rightleftharpoons Ag(CN)_2{}^-(aq)$	5.6×10^8
$Ag^+(aq) + 2\,NH_3(aq) \rightleftharpoons Ag(NH_3)_2{}^+(aq)$	1.6×10^7
$Au^+(aq) + 2\,CN^-(aq) \rightleftharpoons Au(CN)_2{}^-(aq)$	2.0×10^{38}
$Cu^{2+}(aq) + 4\,NH_3(aq) \rightleftharpoons Cu(NH_3)_4{}^{2+}(aq)$	1.2×10^{13}
$Hg^{2+}(aq) + 4\,Cl^-(aq) \rightleftharpoons HgCl_4{}^{2-}(aq)$	1.2×10^5
$Fe^{2+}(aq) + 6\,CN^-(aq) \rightleftharpoons Fe(CN)_6{}^{4-}(aq)$	7.7×10^{36}
$Ni^{2+}(aq) + 6\,NH_3(aq) \rightleftharpoons Ni(NH_3)_6{}^{2+}(aq)$	5.6×10^8

PLAN First, we write the chemical equation for the equilibrium between the solid solute and the complex in solution as the sum of the equations for the solubility and complex formation equilibria. The equilibrium constant for the overall equilibrium is therefore the product of the equilibrium constants for the two processes. Then, we set up an equilibrium table and solve for the equilibrium concentrations of ions in solution.

SOLVE The overall equilibrium is the sum of reactions E and F:

$$AgCl(s) + 2\,NH_3(aq) \rightleftharpoons Ag(NH_3)_2^{+}(aq) + Cl^{-}(aq)$$

The equilibrium constant of the overall reaction is the product of the equilibrium constants for the two reactions:

$$K = K_{sp} \times K_f = \frac{[Ag(NH_3)_2^{+}][Cl^{-}]}{[NH_3]^2}$$

Because 1 mol AgCl ≏ 1 mol Cl^-, the molar solubility of AgCl is given by the equation $s = [Cl^-]$. From the balanced overall equation, we see that $[Cl^-] = [Ag(NH_3)_2^{+}]$ in the saturated solution. The equilibrium table, with all concentrations in moles per liter, is

	NH_3	$Ag(NH_3)_2^{+}$	Cl^-
Step 1 Initial molarity	0.10	0	0
Step 2 Change in molarity	$-2x$	$+x$	$+x$
Step 3 Equilibrium molarity	$0.10 - 2x$	x	x

Now determine the value of K and substitute the information from the table.

From $K = K_{sp} \times K_f$,

$$K = (1.6 \times 10^{-10}) \times (1.6 \times 10^{7}) = 2.6 \times 10^{-3}$$

Find $[Cl^-]$ from $K = [Ag(NH_3)_2^{+}][Cl^-]/[NH_3]^2$.

$$K = \frac{x \times x}{(0.10 - 2x)^2} = 2.6 \times 10^{-3}$$

Take the square root of each side.

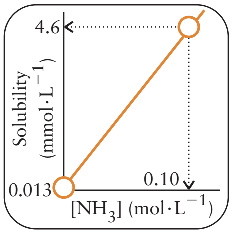
$$\frac{x}{0.10 - x} = 5.1 \times 10^{-2}$$

Solve for x.

$$x = 5.1 \times 10^{-2} \times (0.10 - 2x)$$

Hence

$$x = 4.6 \times 10^{-3}$$



Evaluate From step 3, $x = [Ag(NH_3)_2^{+}] = 4.6 \times 10^{-3}$. Hence, the molar solubility of silver chloride in 0.10 M NH_3(aq) is 4.6 $mmol \cdot L^{-1}$, more than 100 times the molar solubility of silver chloride in pure water (13 $\mu mol \cdot L^{-1}$), as expected.

Self-Test 12.15A Use data from Tables 12.4 and 12.5 to calculate the molar solubility of silver bromide in 1.0 M NH_3(aq).

[***Answer:*** 3.5 $mmol \cdot L^{-1}$]

Self-Test 12.15B Use data from Tables 12.4 and 12.5 to calculate the molar solubility of copper(II) sulfide in 1.2 M NH_3(aq).

The solubility of a salt increases if the salt can form a complex ion with other species in the solution.

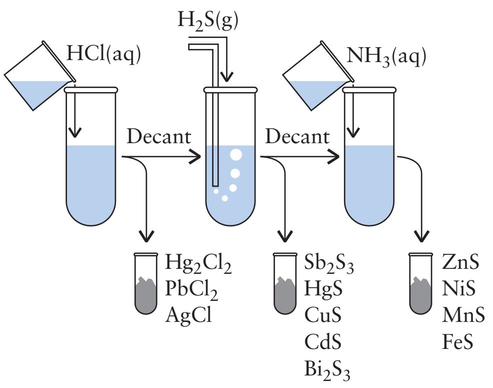


FIGURE 12.20 Part of a simple qualitative analysis scheme used to separate certain cations. In the first step, three cations are separated as insoluble chlorides. In the second step, cations that form highly insoluble sulfides are removed by precipitation at a low pH; and, in the third step, the remaining cations are precipitated as the sulfides at a higher pH.

12.14 Qualitative Analysis

Complex formation, selective precipitation, and control of the pH of a solution all play important roles in the qualitative analysis of the ions present in aqueous solutions. There are many different schemes of analysis, but they follow the same general principles. Let's think through a simple procedure for the identification of five cations by following the steps that might be used in the laboratory. We shall see how each step makes use of solubility equilibria.

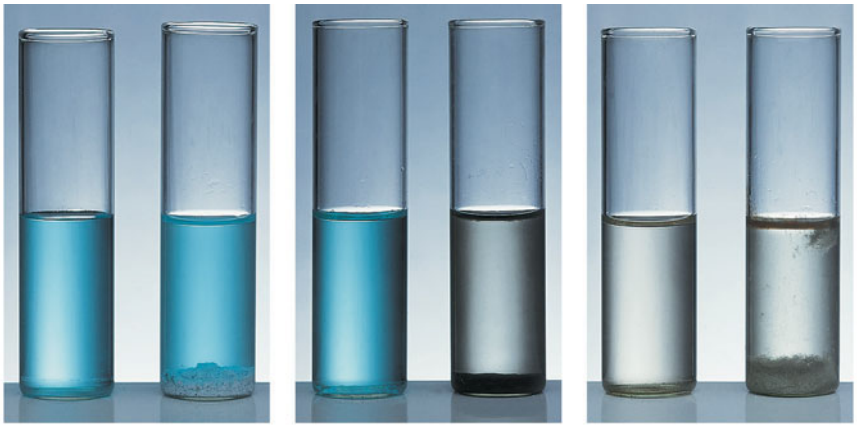
Suppose we have a solution that contains lead(II), mercury(I), silver, copper(II), and zinc ions. The method is outlined in Fig. 12.20, which includes additional cations, and is illustrated in Fig. 12.21. Most chlorides are soluble; so, when hydrochloric acid is added to a mixture of salts, only certain chlorides precipitate (see Table 12.4). Silver and mercury(I) chlorides have such small values of K_{sp} that, even with low concentrations of Cl^- ions, the chlorides precipitate. Lead(II) chloride, which is slightly soluble, will precipitate if the chloride ion concentration is high enough. The hydronium ions provided by the acid play no role in this step; they simply accompany the chloride ions. At this point, the precipitate can be separated from the solution by using a centrifuge to compact the solid and then decanting (pouring off) the solution. The solution now contains copper(II) and zinc ions, whereas the solid consists of $PbCl_2$, Hg_2Cl_2, and AgCl.

Because $PbCl_2$ is slightly soluble, if the precipitate is rinsed with hot water, the lead(II) chloride dissolves and the solution is separated from the precipitate. If sodium chromate is then added to that solution, the presence of lead can be verified because any lead(II) ions present will precipitate as yellow lead(II) chromate:

$$Pb^{2+}(aq) + CrO_4^{\ 2-}(aq) \longrightarrow PbCrO_4(s)$$

At this point, the silver and mercury(I) chlorides remain as precipitates. To separate the Ag^+ and $Hg_2^{\ 2+}$ ions, aqueous ammonia is added to the solid mixture. The silver precipitate dissolves as the soluble complex ion $Ag(NH_3)_2^{\ +}$ forms:

$$Ag^+(aq) + 2\ NH_3(aq) \longrightarrow Ag(NH_3)_2^{\ +}(aq)$$

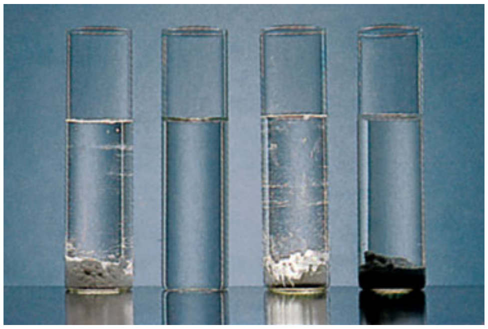


(a) (b) (c)

FIGURE 12.21 Steps in the analysis of five cations by selective precipitation. (a) The original solution contains Pb^{2+}, $Hg_2^{\ 2+}$, Ag^+, Cu^{2+}, and Zn^{2+} ions (left). Addition of HCl precipitates AgCl, Hg_2Cl_2, and $PbCl_2$, which can be removed by decanting or filtration (right), as shown in Fig. 12.22. (b) Addition of H_2S to the solution remaining from the first step (left) precipitates CuS, which can be removed (right). (c) Making the solution from the second step (left) basic by adding ammonia precipitates ZnS (right).

Lab Video 12.21

FIGURE 12.22 When ammonia is added to a silver chloride precipitate, the precipitate dissolves. However, when ammonia is added to a precipitate of mercury(I) chloride, mercury metal and mercury(II) ions are formed in a redox reaction and the mass turns gray. Left to right: silver chloride in water, silver chloride in aqueous ammonia, mercury(I) chloride in water, and mercury(I) chloride in aqueous ammonia.



and mercury(I) reacts with ammonia to form a gray solid consisting of a mixture of mercury(II) ions precipitated as white $HgNH_2Cl(s)$ and black metallic mercury (Fig. 12.22):

$$Hg_2Cl_2(s) + 2\,NH_3(aq) \longrightarrow Hg(l) + HgNH_2Cl(s) + NH_4^+(aq) + Cl^-(aq)$$

At this point, any Hg_2^{2+} has precipitated and any Ag^+ present is in solution. The solution is separated from the solid, and the presence of silver ion in the solution is verified by addition of nitric acid. This acid pulls the ammonia out of the complex as NH_4^+, allowing white silver chloride to precipitate:

$$Ag(NH_3)_2^+(aq) + Cl^-(aq) + 2\,H_3O^+(aq) \longrightarrow AgCl(s) + 2\,NH_4^+(aq) + 2\,H_2O(l)$$

Sulfides with widely different solubilities and solubility products can be selectively precipitated by adding S^{2-} ions to the solution removed from the chlorides in the first step (see Fig. 12.20). Some metal sulfides (such as CuS, HgS, and Sb_2S_3) have extremely small solubility products and precipitate if there is the merest trace of S^{2-} ions in the solution. Such a very low concentration of S^{2-} ions is achieved by adding hydrogen sulfide, H_2S, to an acidified solution. A higher hydronium ion concentration shifts the equilibrium

$$H_2S(aq) + 2\,H_2O(l) \rightleftharpoons 2\,H_3O^+(aq) + S^{2-}(aq)$$

to the left, which ensures that almost all the H_2S is in its fully protonated form and hence that very little S^{2-} is present. Nevertheless, even that very low concentration will result in the precipitation of highly insoluble solids if the appropriate cations are present.

To verify the presence of Zn^{2+} ions in the solution remaining after the first two steps, we add H_2S followed by ammonia. The base removes the hydronium ion from the H_2S equilibrium, which shifts the equilibrium in favor of S^{2-} ions. The higher concentration of S^{2-} ions increases the Q_{sp} values of any remaining metal sulfides, such as ZnS or MnS, above their K_{sp} values, and they precipitate.

Qualitative analysis involves the separation and identification of ions by selective precipitation, complex formation, and the control of pH.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Calculate the pH of a buffer solution (Example 12.1).

❑ 2 Calculate the pH change when acid or base is added to a buffer solution (Example 12.2).

❑ 3 Specify the composition of a buffer solution with a given pH (Example 12.3).

❑ 4 Interpret the features of the pH curve for the titration of a strong or weak acid with a strong base and a strong or weak base with a strong acid (Sections 12.4 and 12.5).

❑ 5 Calculate the pH at any point in a strong base–strong acid titration (Toolbox 12.1 and Example 12.4).

❑ 6 Calculate the pH at any point in a strong base–weak acid and weak base–strong acid titration (Toolbox 12.2 and Examples 12.5 and 12.6).

❑ 7 Select an appropriate indicator for a given titration (Section 12.6).

❑ 8 Identify the primary species in solution and the principal proton transfer equilibrium at any point in the titration of a polyprotic acid (Self-Test 12.9).

❑ 9 Estimate a solubility product from molar solubility and vice versa (Examples 12.7 and 12.8).

❑ 10 Describe the common-ion effect and assess its magnitude (Example 12.9).

❑ 11 Predict whether a salt will precipitate given the concentrations of its ions in water (Example 12.10).

❑ 12 Predict the order of precipitation of a series of salts (Example 12.11).

❑ 13 Calculate molar solubility in the presence of complex ion formation (Example 12.12).

❑ 14 Use a simple qualitative analysis scheme and justify the steps in terms of solubility equilibria (Section 12.14).

EXERCISES

The values of K_a and K_b for weak acids and bases may be found in Tables 11.1 and 11.2.

Mixed Solutions and Buffers

12.1 Explain what happens to (a) the concentration of H_3O^+ ions in an acetic acid solution when solid sodium acetate is added; (b) the percentage deprotonation of benzoic acid in a benzoic acid solution when hydrochloric acid is added; (c) the pH of the solution when solid ammonium chloride is added to aqueous ammonia.

12.2 Explain what happens to (a) the pH of a solution of phosphoric acid after the addition of solid sodium dihydrogen phosphate; (b) the percentage deprotonation of HCN in a hydrocyanic acid solution after the addition of hydrobromic acid; (c) the concentration of H_3O^+ ions when pyridinium chloride is added to an aqueous solution of the base pyridine.

12.3 A solution of equal concentrations of glyceric acid and sodium glycerate was found to have pH = 3.52. (a) What are pK_a and K_a for glyceric acid? (b) What would the pH be if the concentration of acid was twice that of the salt?

12.4 A solution of equal concentrations of barbituric acid and sodium barbiturate was found to have pH = 4.01. (a) What are the values of pK_a and K_a of barbituric acid? (b) What would the pH be if the concentration of acid was twice that of the salt?

12.5 What is the concentration of hydronium ions in (a) a solution that is 0.075 M HCN(aq) and 0.060 M NaCN(aq); (b) a solution that is 0.20 M NH_2NH_2(aq) and 0.30 M NaCl(aq); (c) a solution that is 0.015 M HCN(aq) and 0.030 M NaCN(aq); (d) a solution that is 0.125 M NH_2NH_2(aq) and 0.125 M NH_2NH_3Br(aq)?

12.6 What is the concentration of hydronium ions in (a) a solution that is 0.12 M HBrO(aq) and 0.160 M NaBrO(aq); (b) a solution that is 0.250 M CH_3NH_2(aq) and 0.150 M CH_3NH_3Cl(aq); (c) a solution that is 0.160 M HBrO(aq) and 0.320 M NaBrO(aq); (d) a solution that is 0.250 M CH_3NH_2(aq) and 0.250 M NaBr(aq)?

12.7 Determine the pH and pOH of (a) a solution that is 0.50 M $NaHSO_4$(aq) and 0.25 M Na_2SO_4(aq); (b) a solution that is 0.50 M $NaHSO_4$(aq) and 0.10 M Na_2SO_4(aq); (c) a solution that is 0.50 M $NaHSO_4$(aq) and 0.50 M Na_2SO_4(aq).

12.8 Calculate the pH and pOH of (a) a solution that is 0.17 M Na_2HPO_4(aq) and 0.25 M Na_3PO_4(aq); (b) a solution that is 0.66 M Na_2HPO_4(aq) and 0.42 M Na_3PO_4(aq); (c) a solution that is 0.12 M Na_2HPO_4(aq) and 0.12 M Na_3PO_4(aq).

12.9 Calculate the pH of the solution that results from mixing (a) 30.0 mL of 0.050 M HCN(aq) with 70.0 mL of 0.030 M NaCN(aq); (b) 40.0 mL of 0.030 M HCN(aq) with 60.0 mL of 0.050 M NaCN(aq); (c) 25.0 mL of 0.105 M HCN(aq) with 25.0 mL of 0.105 M NaCN(aq).

12.10 Calculate the pH of the solution that results from mixing (a) 0.200 L of 0.050 M $(CH_3)_2NH$(aq) with 0.320 L of 0.040 M $(CH_3)_2NH_2Cl$(aq); (b) 72.0 mL of 0.015 M $(CH_3)_2NH$(aq) with 20.0 mL of 0.200 M $(CH_3)_2NH_2Cl$(aq); (c) 150.0 mL of 0.060 M $(CH_3)_2NH$(aq) with 30.0 mL of 0.080 M $(CH_3)_2NH_2Cl$(aq).

12.11 A buffer solution of volume 100.0 mL is 0.100 M CH_3COOH(aq) and 0.100 M $NaCH_3CO_2$(aq). (a) What are the pH and the pH change resulting from the addition of 10.0 mL of 0.950 M NaOH(aq) to the buffer solution? (b) What are the pH and the pH change resulting from the addition of 20.0 mL of 0.100 M HNO_3(aq) to the initial buffer solution?

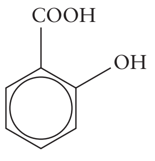
12.12 A buffer solution of volume 100.0 mL is 0.150 M Na_2HPO_4(aq) and 0.100 M KH_2PO_4(aq). (a) What are the pH and the pH change resulting from the addition of 80.0 mL of 0.0100 M NaOH(aq) to the buffer solution? (b) What are the pH and the pH change resulting from the addition of 10.0 mL of 1.0 M HNO_3(aq) to the initial buffer solution?

12.13 The pH of 0.40 M HF(aq) is 1.93. Calculate the change in pH when 0.356 g of sodium fluoride is added to 50.0 mL of the solution. Ignore any change in volume.

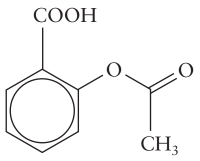
12.14 The pH of 0.50 M HBrO(aq) is 4.50. Calculate the change in pH when 6.80 g of sodium hypobromite is added to 100. mL of the solution. Ignore any change in volume.

12.15 Sodium hypochlorite, NaClO, is the active ingredient in many bleaches. Calculate the ratio of the concentrations of ClO^- and HClO in a bleach solution having a pH adjusted to 6.50 by the use of strong acid or strong base.

12.16 Aspirin (shown here as acetylsalicylic acid, $K_a = 3.2 \times 10^{-4}$) is a product of the reaction of salicylic acid with acetic anhydride. Calculate the ratio of the concentrations of the acetylsalicylate ion to acetylsalicylic acid in a solution that has a pH adjusted to 4.13 by the use of strong acid or strong base.



Salicylic acid



Acetylsalicylic acid

12.17 Predict the pH region in which each of the following buffers will be effective, assuming equal molarities of the acid and its conjugate base: (a) sodium lactate and lactic acid; (b) sodium benzoate and benzoic acid; (c) potassium hydrogen phosphate and potassium phosphate; (d) potassium hydrogen phosphate and potassium dihydrogen phosphate; (e) hydroxylamine and hydroxylammonium chloride.

12.18 Predict the pH region in which each of the following buffers will be effective, assuming equal molarities of the acid and its conjugate base: (a) sodium nitrite and nitrous acid; (b) sodium formate and formic acid; (c) sodium carbonate and sodium hydrogen carbonate; (d) ammonia and ammonium chloride; (e) pyridine and pyridinium chloride.

12.19 Use Tables 11.1, 11.2, and 11.9 to suggest a conjugate acid–base system that would be an effective buffer at a pH close to (a) 2; (b) 7; (c) 3; (d) 12.

12.20 Use Tables 11.1, 11.2, and 11.9 to suggest a conjugate acid–base system that would be an effective buffer at a pH close to (a) 4; (b) 9; (c) 5; (d) 11.

12.21 (a) What must be the ratio of the concentrations of CO_3^{2-} and HCO_3^- ions in a buffer solution having a pH of 11.0? (b) What mass of K_2CO_3 must be added to 1.00 L of 0.100 M $KHCO_3$(aq) to prepare a buffer solution with a pH of 11.0? (c) What mass of $KHCO_3$ must be added to 1.00 L of 0.100 M K_2CO_3(aq) to prepare a buffer solution with a pH of 11.0? (d) What volume of 0.200 M K_2CO_3(aq) must be added to 100. mL of 0.100 M $KHCO_3$(aq) to prepare a buffer solution with a pH of 11.0?

12.22 (a) What must be the ratio of the molarities of PO_4^{3-} and HPO_4^{2-} ions in a buffer solution having a pH of 12.0? (b) What mass of K_3PO_4 must be added to 1.00 L of 0.100 M K_2HPO_4(aq) to prepare a buffer solution with a pH of 12.0? (c) What mass of K_2HPO_4 must be added to 1.00 L of 0.100 M K_3PO_4(aq) to prepare a buffer solution with a pH of 12.0? (d) What volume of 0.150 M K_3PO_4(aq) must be added to 50.0 mL of 0.100 M K_2HPO_4(aq) to prepare a buffer solution with a pH of 12.0?

Titrations

12.23 (a) Sketch the titration curve for the titration of 5.00 mL 0.010 M NaOH(aq) with 0.005 M HCl(aq), indicating the pH of the initial and final solutions and the pH at the stoichiometric point. What volume of HCl has been added at (b) the stoichiometric point; (c) the halfway point of the titration?

12.24 (a) Sketch the titration curve for the titration of 5.00 mL 0.010 M HCl(aq) with 0.010 M $Ca(OH)_2$(aq), indicating the pH of the initial and final solutions and the pH at the stoichiometric point. What volume of titrant has been added at (b) the stoichiometric point; (c) the halfway point of the titration?

12.25 Calculate the volume of 0.150 M HCl(aq) required to neutralize (a) one-half and (b) all the hydroxide ions in 25.0 mL of 0.110 M NaOH(aq). (c) What is the molarity of Na^+ ions at the stoichiometric point? (d) Calculate the pH of the solution after the addition of 20.0 mL of 0.150 M HCl(aq) to 25.0 mL of 0.110 M NaOH(aq).

12.26 Calculate the volume of 0.125 M HCl(aq) required to neutralize (a) one-half and (b) all the hydroxide ions in 25.0 mL of 0.305 M KOH(aq). (c) What is the molarity of Cl^- ions at the stoichiometric point? (d) Calculate the pH of the solution after the addition of 35.0 mL of 0.125 M HCl(aq) to 25.0 mL of 0.305 M KOH(aq).

12.27 Suppose that 4.25 g of an unknown monoprotic weak acid, HA, is dissolved in water. Titration of the solution with 0.350 M NaOH(aq) required 52.0 mL to reach the stoichiometric point. After the addition of 26.0 mL, the pH of the solution was found to be 3.82. (a) What is the molar mass of the acid? (b) What is the value of pK_a for the acid?

12.28 Suppose that 0.483 g of an unknown monoprotic weak acid, HA, is dissolved in water. Titration of the solution with 0.250 M NaOH(aq) required 42.0 mL to reach the stoichiometric point. After the addition of 21.0 mL, the pH of the solution was found to be 3.75. (a) What is the molar mass of the acid? (b) What is the value of pK_a for the acid? Can you identify the acid?

12.29 Calculate the pH at each stage in the titration for the addition of 0.150 M HCl(aq) to 25.0 mL of 0.110 M NaOH(aq): (a) initially; (b) after the addition of 5.0 mL of acid; (c) after the addition of a further 5.0 mL; (d) at the stoichiometric point; (e) after the addition of 5.0 mL of acid beyond the stoichiometric point; (f) after the addition of 10.0 mL of acid beyond the stoichiometric point.

12.30 Calculate the pH at each stage in the titration in which 0.116 M HCl(aq) is added to 25.0 mL of 0.215 M KOH(aq): (a) initially; (b) after the addition of 5.0 mL of acid; (c) after the addition of a further 5.0 mL; (d) at the stoichiometric point; (e) after the addition of 5.0 mL of acid beyond the stoichiometric point; (f) after the addition of 10.0 mL of acid beyond the stoichiometric point.

12.31 Suppose that 1.436 g of impure sodium hydroxide is dissolved in 300. mL of aqueous solution and that 25.00 mL of this solution is titrated to the stoichiometric point with 34.20 mL of 0.0695 M HCl(aq). What is the percentage purity of the original sample?

12.32 Suppose that 1.652 g of impure barium hydroxide is dissolved in enough water to produce 200. mL of solution and that 25.0 mL of this solution is titrated to the stoichiometric point with 14.7 mL of 0.0825 M HCl(aq). What is the percentage purity of the original sample?

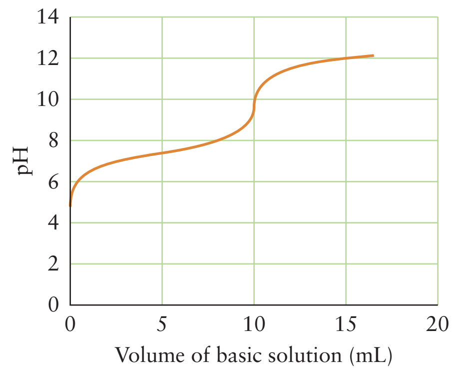
12.33 Suppose that 25.0 mL of 0.10 M CH_3COOH(aq) is titrated with 0.10 M NaOH(aq). (a) What is the initial pH of the 0.10 M CH_3COOH(aq) solution? (b) What is the pH after the addition of 10.0 mL of 0.10 M NaOH(aq)? (c) What volume of 0.10 M NaOH(aq) is required to reach halfway to the stoichiometric point? (d) Calculate the pH at that halfway point. (e) What volume of 0.10 M NaOH(aq) is required to reach the stoichiometric point? (f) Calculate the pH at the stoichiometric point.

12.34 Suppose that 30.0 mL of 0.20 M C_6H_5COOH(aq) is titrated with 0.30 M KOH(aq). (a) What is the initial pH of the 0.20 M C_6H_5COOH(aq)? (b) What is the pH after the addition of 15.0 mL of 0.30 M KOH(aq)? (c) What volume of 0.30 M KOH(aq) is required to reach halfway to the stoichiometric point? (d) Calculate the pH at the halfway point. (e) What volume of 0.30 M KOH(aq) is required to reach the stoichiometric point? (f) Calculate the pH at the stoichiometric point.

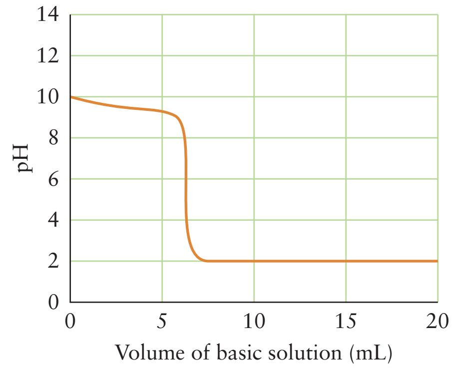
12.35 Suppose that 15.0 mL of 0.15 M NH_3(aq) is titrated with 0.10 M HCl(aq). (a) What is the initial pH of the 0.15 M NH_3(aq)? (b) What is the pH after the addition of 15.0 mL of 0.10 M HCl(aq)? (c) What volume of 0.10 M HCl(aq) is required to reach halfway to the stoichiometric point? (d) Calculate the pH at the halfway point. (e) What volume of 0.10 M HCl(aq) is required to reach the stoichiometric point? (f) Calculate the pH at the stoichiometric point. (g) Use Table 12.3 to select an indicator for the titration.

12.36 Suppose that 50.0 mL of 0.25 M CH_3NH_2(aq) is titrated with 0.35 M HCl(aq). (a) What is the initial pH of the 0.25 M CH_3NH_2(aq)? (b) What is the pH after the addition of 15.0 mL of 0.35 M HCl(aq)? (c) What volume of 0.35 M HCl(aq) is required to reach halfway to the stoichiometric point? (d) Calculate the pH at the halfway point. (e) What volume of 0.35 M HCl(aq) is required to reach the stoichiometric point? (f) Calculate the pH at the stoichiometric point. (g) Use Table 12.3 to select an indicator for the titration.

12.37 Following is the titration curve for the neutralization of 25 mL of a monoprotic acid with a strong base. Answer the following questions about the reaction and explain your reasoning in each case. (a) Is the acid strong or weak? (b) What is the initial hydronium ion concentration of the acid? (c) What is K_a for the acid? (d) What is the initial concentration of the acid? (e) What is the concentration of base in the titrant? (f) Use Table 12.3 to select an indicator for the titration.



12.38 Below is the titration curve for the neutralization of 25 mL of a base with a strong monoprotic acid. Answer the following questions about the reaction and explain your reasoning in each case. (a) Is the base strong or weak? (b) What is the initial hydroxide ion concentration of the base? (c) What is K_b for the base? (d) What is the initial concentration of the base? (e) What is the concentration of acid in the titrant? (f) Use Table 12.3 to select an indicator for the titration.



12.39 Which of the following indicators (see Table 12.3) could you use for a titration of 0.20 M CH_3COOH(aq) with 0.20 M NaOH(aq): (a) methyl orange; (b) litmus; (c) thymol blue; (d) phenolphthalein? Explain your selections.

12.40 Which of the following indicators (see Table 12.3) could you use for a titration of 0.20 M NH_3(aq) with 0.20 M HCl(aq): (a) bromocresol green; (b) methyl red; (c) phenol red; (d) thymol blue? Explain your selections.

12.41 Use Table 12.3 to suggest suitable indicators for the titrations described in Exercises 12.33 and 12.35.

12.42 Use Table 12.3 to suggest suitable indicators for the titrations described in Exercises 12.34 and 12.36.

Polyprotic Acid Titrations

12.43 What volume of 0.275 M KOH(aq) must be added to 75.0 mL of 0.137 M H_3AsO_4(aq) to reach (a) the first stoichiometric point; (b) the second stoichiometric point; (c) the third stoichiometric point?

12.44 What volume of 0.123 M NaOH(aq) must be added to 125 mL of 0.197 M H_2SO_3(aq) to reach (a) the first stoichiometric point; (b) the second stoichiometric point?

12.45 What volume of 0.255 M HNO_3(aq) must be added to 35.5 mL of 0.158 M Na_2HPO_3(aq) to reach (a) the first stoichiometric point; (b) the second stoichiometric point?

12.46 What volume of 0.0848 M HCl(aq) must be added to 88.8 mL of 0.233 M Na_3PO_4(aq) to reach (a) the first stoichiometric point; (b) the second stoichiometric point; (c) the third stoichiometric point?

12.47 (a) Sketch the titration curve for the titration of 5.00 mL 0.010 M $H_2S_2O_3$(aq) with 0.010 M KOH(aq), identifying the initial and final points, the stoichiometric points, and each of the halfway points. (b) What volume of KOH has been added at each stoichiometric point? (c) Determine the pH at each stoichiometric point. For $H_2S_2O_3$(aq), $pK_{a1} = 0.6$ and $pK_{a2} = 1.74$.

12.48 (a) Sketch the titration curve for the titration of 5.00 mL 0.010 M H_3AsO_4(aq) with 0.010 M KOH(aq), identifying the initial and final points, the stoichiometric points, and each of the halfway points. (b) What volume of KOH has been added at each stoichiometric point? (c) Determine the pH at each stoichiometric point. For H_3AsO_4(aq), $pK_{a1} = 2.25$ and $pK_{a2} = 6.77$.

12.49 Suppose that 0.122 g of phosphorous acid, H_3PO_3, is dissolved in water and that the total volume of the solution is 50.0 mL. (a) Estimate the pH of this solution. (b) Estimate the pH of the solution that results when 5.00 mL of 0.175 M NaOH(aq) is added to the phosphorous acid solution. (c) Estimate the pH of the solution if an additional 5.00 mL of 0.175 M NaOH(aq) is added to the solution in part (b).

12.50 Suppose that 0.242 g of oxalic acid, $(COOH)_2$, is dissolved in 50.0 mL of water. (a) Estimate the pH of this solution. (b) Estimate the pH of the solution that results when 15.0 mL of 0.150 M NaOH(aq) is added to the oxalic acid solution. (c) Estimate the pH of the solution that results if an additional 5.00 mL of NaOH(aq) solution is added to the solution from part (b).

12.51 Estimate the pH of the solution that results when each of the following solutions is added to 50.0 mL of 0.275 M Na_2HPO_4(aq): (a) 50.0 mL of 0.275 M HCl(aq); (b) 75.0 mL of 0.275 M HCl(aq); (c) 25.0 mL of 0.275 M HCl(aq).

12.52 Estimate the pH of the solution that results when 75.0 mL of 0.0995 M Na_2CO_3(aq) is mixed with (a) 25.0 mL of 0.130 M HNO_3(aq); (b) 65.0 mL of 0.130 M HNO_3(aq).

Solubility Equilibria

The values for the solubility products of some sparingly soluble salts are listed in Table 12.4.

12.53 Determine K_{sp} for each of the following sparingly soluble substances, given their molar solubilities: (a) AgBr, 8.8×10^{-7} mol·L^{-1}; (b) $PbCrO_4$, 1.3×10^{-7} mol·L^{-1}; (c) $Ba(OH)_2$, 0.11 mol·L^{-1}; (d) MgF_2, 1.2×10^{-3} mol·L^{-1}. For the purpose of this calculation, ignore any reaction of the anion with water and the autoprotolysis of water.

12.54 Determine K_{sp} for each of the following sparingly soluble compounds, given their molar solubilities: (a) AgI, 9.1×10^{-9} mol·L^{-1}; (b) $Ca(OH)_2$, 0.011 mol·L^{-1}; (c) Ag_3PO_4, 2.7×10^{-6} mol·L^{-1}; (d) Hg_2Cl_2, 5.2×10^{-7} mol·L^{-1}. For the purpose of this calculation, ignore any reaction of the anion with water and the autoprotolysis of water.

12.55 The molarity of CrO_4^{2-} in a saturated Tl_2CrO_4 solution is 6.3×10^{-5} mol·L^{-1}. What is the K_{sp} of Tl_2CrO_4?

12.56 The molar solubility of cerium(III) hydroxide, $Ce(OH)_3$, is 5.2×10^{-6} mol·L^{-1}. What is the K_{sp} of cerium(III) hydroxide? For the purpose of this calculation, ignore the autoprotolysis of water.

12.57 Calculate the molar solubility in water of (a) BiI_3 ($K_{sp} = 7.71 \times 10^{-19}$); (b) CuCl; (c) $CaCO_3$. For the purpose of this calculation, ignore any reaction of the anion with water.

12.58 Calculate the molar solubility in water of (a) $PbBr_2$; (b) Ag_2CO_3; (c) $Fe(OH)_2$. For the purpose of this calculation, ignore any reaction of the anion with water and the autoprotolysis of water.

12.59 Use the data in Table 12.4 to calculate the molar solubility of each sparingly soluble substance in its respective solution: (a) silver chloride in 0.20 M NaCl(aq); (b) mercury(I) chloride in 0.150 M NaCl(aq); (c) lead(II) chloride in 0.025 M $CaCl_2$(aq); (d) iron(II) hydroxide in 2.5×10^{-3} M $FeCl_2$(aq). For the purpose of this calculation, ignore the autoprotolysis of water.

12.60 Use the data in Table 12.4 to calculate the solubility of each sparingly soluble substance in its respective solution: (a) silver bromide in 0.040 M NaBr(aq); (b) magnesium carbonate in 2.0×10^{-3} M Na_2CO_3(aq); (c) lead(II) sulfate in 0.15 M Na_2SO_4(aq); (d) nickel(II) hydroxide in 0.215 M $NiSO_4$(aq). For the purpose of this calculation, ignore the autoprotolysis of water.

12.61 Use the data in Table 12.4 to calculate the solubility of each of the following sparingly soluble substances in its respective solution: aluminum hydroxide at (a) pH = 7.0; (b) pH = 4.5; zinc hydroxide at (c) pH = 7.0; (d) pH = 6.0.

12.62 Use the data in Table 12.4 to calculate the solubility of each of the following sparingly soluble compounds in its respective solution: iron(III) hydroxide at (a) pH = 11.0; (b) pH = 3.0; iron(II) hydroxide at (c) pH = 8.0; (d) pH = 6.0.

12.63 (a) What molarity of Ag^+ ions is required for the formation of a precipitate in 1.0×10^{-5} M NaCl(aq)? (b) What mass (in micrograms) of solid $AgNO_3$ needs to be added for the onset of precipitation in 100. mL of the solution in part (a)?

12.64 Iodide ions can be used to precipitate lead(II) ions from 0.0030 M $Pb(NO_3)_2$(aq). (a) What minimum iodide ion concentration is required for the onset of PbI_2 precipitation? (b) What mass (in grams) of KI must be added for PbI_2 to form?

12.65 Determine the pH required for the onset of precipitation of $Ni(OH)_2$ from (a) 0.060 M $NiSO_4$(aq); (b) 0.030 M $NiSO_4$(aq).

12.66 Decide whether a precipitate will form when each of the following pairs of solutions are mixed: (a) 5.0 mL of 0.10 M K_2CO_3(aq) and 1.00 L of 0.010 M $AgNO_3$(aq); (b) 3.3 mL of 1.0 M HCl(aq), 4.9 mL of 0.0030 M $AgNO_3$(aq), and enough water to dilute the solution to 50.0 mL. For the purpose of this calculation, ignore any reaction of the anion with water.

12.67 Suppose that there are typically 20 average-sized drops in 1.0 mL of an aqueous solution. Will a precipitate form when 1 drop of 0.010 M NaCl(aq) is added to 10.0 mL of (a) 0.0040 M $AgNO_3$(aq); (b) 0.0040 M $Pb(NO_3)_2$(aq)?

12.68 Assume 20 drops per milliliter. Will a precipitate form if (a) 7 drops of 0.0029 M K_2CO_3(aq) are added to 25.0 mL of 0.0018 M $CaCl_2$(aq); (b) 10 drops of 0.010 M Na_2CO_3(aq) are added to 10.0 mL of 0.0040 M $AgNO_3$(aq)? For the purpose of this calculation, ignore any reaction of the anion with water.

12.69 The concentrations of magnesium, calcium, and nickel(II) ions in an aqueous solution are 0.0010 mol·L^{-1}. (a) In what order do they precipitate when solid KOH is added? (b) Determine the pH at which each salt precipitates.

12.70 Suppose that two hydroxides, MOH and M′$(OH)_2$, both have $K_{sp} = 1.0 \times 10^{-12}$ and that initially both cations are present in a solution at concentrations of 0.0010 mol·L^{-1}. Which hydroxide precipitates first, and at what pH, when solid NaOH is added?

12.71 We wish to separate magnesium ions and barium ions by selective precipitation. Which anion, fluoride or carbonate, would be the better choice for achieving this precipitation? Why?

12.72 We wish to separate barium ions from calcium ions by selective precipitation. Which anion, fluoride or carbonate, would be the better choice for achieving this precipitation? Why?

12.73 In the process of separating Pb^{2+} ions from Cu^{2+} ions as sparingly soluble iodates, what is the Pb^{2+} concentration when Cu^{2+} just begins to precipitate as sodium iodate is added to a solution that is initially 0.0010 M $Pb(NO_3)_2$(aq) and 0.0010 M $Cu(NO_3)_2$(aq)?

12.74 A chemist attempts to separate barium ions from lead ions by using the sulfate ion as a precipitating agent. (a) What sulfate ion concentrations are required for the precipitation of $BaSO_4$ and $PbSO_4$ from a solution containing 0.010 M Ba^{2+}(aq) and 0.010 M Pb^{2+}(aq)? (b) What is the concentration of barium ions when the lead sulfate begins to precipitate?

12.75 Consider the two equilibria

$$CaF_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\,F^-(aq) \qquad K_{sp} = 4.0 \times 10^{-11}$$

$$F^-(aq) + H_2O(l) \rightleftharpoons HF(aq) + OH^-(aq) \qquad K_b(F^-) = 2.9 \times 10^{-11}$$

(a) Write the chemical equation for the overall equilibrium and determine the corresponding equilibrium constant. Determine the solubility of CaF_2 at (b) pH = 7.0; (c) pH = 3.0.

12.76 Consider the two equilibria

$$BaF_2(s) \rightleftharpoons Ba^{2+}(aq) + 2\,F^-(aq) \qquad K_{sp} = 1.7 \times 10^{-6}$$

$$F^-(aq) + H_2O(l) \rightleftharpoons HF(aq) + OH^-(aq) \qquad K_b(F^-) = 2.9 \times 10^{-11}$$

(a) Write the chemical equation for the overall equilibrium and determine the corresponding equilibrium constant. Determine the solubility of BaF_2 at (b) pH = 7.0; (c) pH = 5.0.

12.77 Calculate the solubility of silver bromide in 0.10 M KCN(aq). Refer to Tables 12.4 and 12.5.

12.78 Precipitated silver chloride dissolves in ammonia solutions as a result of the formation of $Ag(NH_3)_2{}^+$. What is the solubility of silver chloride in 1.0 M NH_3(aq)? Refer to Tables 12.4 and 12.5.

12.79 You find a bottle of a pure silver halide that could be AgCl or AgI. Develop a simple chemical test that would allow you to distinguish which compound was in the bottle.

12.80 Which of the following compounds, if either, will dissolve in 1.00 M HNO_3(aq): (a) Bi_2S_3(s); (b) FeS(s)? Substantiate your answer by giving an appropriate calculation.

12.81 A metal alloy sample is believed to contain silver, bismuth, and nickel. Explain how it could be determined qualitatively that all three of these metals are present.

12.82 Zinc(II) readily forms the complex ion $Zn(OH)_4{}^{2-}$. Explain how this fact can be used to distinguish a solution of $ZnCl_2$ from $MgCl_2$.

Integrated Exercises

12.83 A buffer solution containing equal amounts of acetic acid and sodium acetate is prepared. What concentration of the buffer must be prepared to prevent a change in the pH by more than 0.20 pH units after the addition of 1.00 mL of 6.00 M HCl(aq) to 100.0 mL of the buffer solution?

12.84 You require 0.150 L of a buffer with pH = 3.00. On the shelf is a bottle of trichloracetic acid/sodium trichloracetate buffer with pH = 2.95. The label also says [trichloracetate ion] = 0.200 M. What mass of which substance (trichloracetic acid or sodium trichloracetate) should you add to 0.150 L of the buffer to obtain the desired pH?

12.85 Malonic acid, $HOOCCH_2COOH$, a diprotic acid with $pK_{a1} = 2.8$ and $pK_{a2} = 5.7$, is titrated with KOH(aq). (a) What is the pH when $[HOOCCH_2COOH] = [HOOCCH_2CO_2^-]$? (b) What is the pH when $[HOOCCH_2CO_2^-] = [^-O_2CCH_2CO_2^-]$? (c) Which is the predominant species at pH = 4.2?

12.86 A species that can accept two protons is classified as dibasic. The dibasic molecule 1,2-ethanediamine, $H_2NC_2H_4NH_2$, which has $pK_{b1} = 3.19$ and $pK_{b2} = 6.44$, is titrated with HCl(aq). (a) What is the pH when $[H_2NC_2H_4NH_2] = [H_2NC_2H_4NH_3^+]$? (b) What is the pH when $[H_2NC_2H_4NH_3^+] = [^+H_3NC_2H_4NH_3^+]$? (c) Which is the predominant species at pH = 4.8?

12.87 Novocaine, which is used by dentists as a local anesthetic, is a weak base with $pK_b = 5.05$. Blood has a pH of 7.4. What is the ratio of the concentration of novocaine to that of its conjugate acid in the bloodstream?

12.88 To simulate blood conditions, a phosphate buffer system with a pH = 7.40 is desired. What mass of Na_2HPO_4 must be added to 0.500 L of 0.10 M NaH_2PO_4(aq) to prepare such a buffer?

12.89 A buffer is prepared by adding 55.0 mL of 0.15 M HNO_3(aq) to 45.0 mL of 0.65 M $NaC_6H_5CO_2$(aq). Determine the solubility of PbF_2 in this buffer solution.

12.90 A buffer is prepared by adding 25.0 mL of 0.12 M HCl(aq) to 55.0 mL of 0.52 M $NaCH_3CO_2$(aq). What is the solubility of BaF_2 in this buffer solution?

12.91 For some diprotic acids, such as oxalic acid, the titration curve has two distinct stoichiometric points, but in other cases, such as tartaric acid, only one stoichiometric point, with a rise that is not very steep, can be observed. Explain the differences in these two titration curves.

12.92 A 25.0-mL sample of 0.150 M Na_2CO_3(aq) is titrated with 0.100 M HCl(aq). What is the pH of the solution at each stoichiometric point in the titration?

12.93 Which sulfide precipitates first when sulfide ions are added to a solution containing equal concentrations of Co^{2+}, Cu^{2+}, and Cd^{2+}? For CoS, $K_{sp} = 5 \times 10^{-22}$. Explain your conclusions.

12.94 You decide to use sulfide precipitation to separate the copper(II) ions from the manganese(II) ions in a solution that is 0.20 M Cu^{2+}(aq) and 0.20 M Mn^{2+}(aq). Determine the minimum sulfide ion concentration that will result in the precipitation of one cation (identify the cation) but not the other.

12.95 In a precipitation titration the concentration of an ion is measured as it forms a precipitate. For example, the concentration of CO_3^{2-} ions in a 25.0-mL sample was determined by titrating with 0.110 M $AgNO_3$(aq). Before the stoichiometric point, the Ag^+ ions react immediately with the CO_3^{2-} ions, but after the stoichiometric point the concentration of Ag^+ ion increases rapidly. (a) The stoichiometric point is reached after the addition of 36.2 mL of the $AgNO_3$(aq). What is the concentration of CO_3^{2-} ions in the sample? (b) The concentration of Ag ion is followed by using a special electrode and measuring pAg (–log $[Ag^+]$). Sketch the plot of pAg against volume of $AgNO_3$(aq) and determine the value of pAg at the stoichiometric point.

12.96 What volume (in liters) of a saturated mercury(II) sulfide, HgS, solution contains an average of one mercury(II) ion, Hg^{2+}?

12.97 In an attempt to determine the concentration of sulfur dioxide in the air near a power plant, two students set up a bubbler that passes air through 50.00 mL of 1.0×10^{-4} M NaOH(aq). The temperature is 22°C, and the atmospheric pressure 753 Torr. The air is pumped for 2.5 h at a flow rate of $3.0\ L\cdot h^{-1}$. The students then returned to the laboratory and titrated the solution with 1.5×10^{-4} M HCl(aq) with phenolphthalein indicator to see how much NaOH was left unreacted. They found that 30.2 mL of HCl(aq) was required to reach the stoichiometric point. (a) Write the balanced chemical equation for the reaction of SO_2 and water. (b) What amount of NaOH (in mol) had reacted with the SO_2? (c) What was the concentration of sulfur dioxide in the air, in parts per million?

12.98 Consider the equilibria

$$ZnS(s) \rightleftharpoons Zn^{2+}(aq) + S^{2-}(aq)$$

$$S^{2-}(aq) + H_2O(l) \rightleftharpoons HS^-(aq) + OH^-(aq)$$

$$HS^-(aq) + H_2O(l) \rightleftharpoons H_2S(aq) + OH^-(aq)$$

Write the chemical equation for the overall equilibrium and determine the corresponding equilibrium constant. (b) Determine the solubility of ZnS in a saturated H_2S solution (0.1 M H_2S(aq)) adjusted to pH = 7.0. (c) Determine the solubility of ZnS in a saturated H_2S solution (0.1 M H_2S(aq)) adjusted to pH = 10.0.

12.99 Using data available in the tables and appendices, calculate the standard Gibbs free energy of formation of PbF_2(s).

12.100 Silver iodide is very insoluble in water. A common method for increasing its solubility is to increase the temperature of the solution containing the solid. Estimate the solubility of AgI at 85°C.

12.101 The main buffer in the blood consists primarily of hydrogen carbonate ions (HCO_3^-) and H_3O^+ ions in equilibrium with water and CO_2:

$$H_3O^+(aq) + HCO_3^-(aq) \rightleftharpoons 2\,H_2O(l) + CO_2(aq) \qquad K = 7.9 \times 10^{-7}$$

This reaction assumes that all H_2CO_3 produced decomposes completely to CO_2 and H_2O. Suppose that 1.0 L of blood is removed from the body and brought to pH = 6.1. (a) If the concentration of HCO_3^- is $5.5\ \mu mol\cdot L^{-1}$, calculate the amount (in moles) of CO_2 present in the solution at this pH. (b) Calculate the change in pH that occurs when 0.65 μmol H_3O^+ is added to this sample of blood at this pH (that is, pH = 6.1). See Box 12.1.

12.102 The pH of the blood is maintained by a finely tuned buffering system, consisting primarily of hydrogen carbonate ion (HCO_3^-) and H_3O^+ in equilibrium with water and CO_2.

$$H_3O^+(aq) + HCO_3^-(aq) \rightleftharpoons H_2CO_3(aq) + H_2O(l)$$

$$H_3O^+(aq) + HCO_3^-(aq) \rightleftharpoons 2\,H_2O(l) + CO_2(g)$$

During exercise, CO_2 is produced at a rapid rate in muscle tissue. (a) How does exercise affect the pH of blood? (b) Hyperventilation (rapid and deep breathing) can occur during intense exertion. How does hyperventilation affect the pH of the blood? (c) The normal first-aid treatment for hyperventilation is to have the patient breathe into a paper bag. Explain briefly why this treatment works and tell what effect the paper-bag treatment has on the pH of the blood. See Box 12.1.

12.103 A buffer solution of volume 300.0 mL is 0.200 M $CH_3COOH(aq)$ and 0.300 M $NaCH_3CO_2(aq)$. (a) What is the initial pH of this solution? (b) What mass of NaOH would have to be dissolved in this solution to bring the pH to 6.0?

12.104 A buffer solution of volume 300.0 mL is 0.400 M $NH_3(aq)$ and 0.200 M $NH_4Cl(aq)$. (a) What is the initial pH of this solution? (c) What volume of HCl gas at 2.00 atm and 25°C would have to be dissolved in this solution to bring the pH to 8.0?

Chemistry Connections

12.105 Soluble nontoxic salts such as $Fe_2(SO_4)_3$ are often used during water purification to remove soluble toxic contaminants, because they form gelatinous hydroxides that encapsulate the contaminants and allow them to be filtered from the water.
(a) Calculate the molar solubility in water of $Fe(OH)_3$ at 25°C.
(b) What is the concentration of hydroxide ion in a saturated solution of $Fe(OH)_3$? Calculate the pH of the solution.
(c) Discuss whether your result in part (b) is reasonable for a solution of a basic hydroxide. Explain what assumptions were made in your calculations and evaluate the validity of the assumptions.
(d) A simplified equation for the reaction of Fe^{3+} ions with water is $Fe^{3+}(aq) + 6\,H_2O(l) \rightleftharpoons Fe(OH)_3(s) + 3\,H_3O^+(aq)$. Use the data in Table 12.4 and K_w to calculate the equilibrium constant for this reaction.
(e) If 10.0 g of $Fe_2(SO_4)_3$ is dissolved in enough water to make up 1.00 L of aqueous solution and the pH of the solution is raised to 8.00 by addition of NaOH, what mass of solid $Fe(OH)_3$ will form?
(f) To test for the ability of $Fe_2(SO_4)_3$ to remove chloride ions from water, a standard aqueous solution containing 24.72 g of NaCl in 1.000 L of solution was prepared. A 25.00-mL sample of the NaCl solution was then combined with the mixture described in part (e) and stirred. The $Fe(OH)_3$ precipitate containing encapsulated chloride ion was removed by filtration, then dissolved in acid. An aqueous solution of $AgNO_3$ was then added to the resulting solution and the solid AgCl formed filtered and dried. The mass of AgCl was 0.604 g. What percentage of the chloride ion in the 25.00-mL sample had been removed from the solution?

What Are the Key Ideas? The tendency of electrons to be transferred in a chemical reaction depends on the species involved and their concentrations. When the process is spontaneous and reduction and oxidation occur at different locations, the reaction can do work and drive electrons through an external circuit.

Why Do We Need to Know This Material? The topics described in this chapter may one day unlock a virtually inexhaustible supply of clean energy supplied daily by the Sun. The key is electrochemistry, the study of the interaction of electricity and chemical reactions. The transfer of electrons from one species to another is one of the fundamental processes underlying life, photosynthesis, fuel cells, and the refining of metals. An understanding of how electrons are transferred helps us to design ways to use chemical reactions to generate electricity and to use electricity to bring about chemical reactions. Electrochemical measurements also allow us to determine the values of thermodynamic quantities.

What Do We Need to Know Already? This chapter extends the thermodynamic discussion presented in Chapter 8. In particular, it builds on the concept of Gibbs free energy (Section 8.12), its relation to maximum nonexpansion work (Section 8.14), and the dependence of the reaction Gibbs free energy on the reaction quotient (Section 10.3). For a review of redox reactions, see Section K. To prepare for the quantitative treatment of electrolysis, review stoichiometry in Section L.

The nature of electricity was unknown until the late eighteenth century, when the Italian scientist Luigi Galvani discovered that by touching the muscles of dead animals, mainly frogs, with rods bearing electric charges, he could make their muscles twitch. He believed that electricity came from the muscles themselves. However, at the end of that century another Italian, Alessandro Volta, suggested that the electricity came from the fact that the muscles were between two different metals when touched by the rods. He proved that the electricity came from metals by constructing a tower of alternating discs of different metals in layers separated by paper strips soaked in a solution of sodium chloride (Fig. 13.1). This apparatus, a "voltaic pile," was the first electrical storage device, a simple battery, but because it opened a door to a new understanding of the structure of matter, it amazed the scientists and even the rulers of the day.

Those early observations have evolved into the branch of chemistry called **electrochemistry.** This subject deals not only with the use of spontaneous chemical reactions to produce electricity but also with the use of electricity to drive nonspontaneous reactions forward. Electrochemistry also provides techniques for monitoring chemical reactions and for measuring properties of solutions such as the pK_a of an acid and the thermodynamic characteristics of reactions. Electrochemistry even allows us to monitor the activity of our brain and heart (perhaps while we are trying to master chemistry), the pH of our blood, and the presence of pollutants in our water supply.

REPRESENTING REDOX REACTIONS

An electric current is the flow of electrons through a circuit. When the current is generated chemically, the electrons emerge from a location where oxidation takes place and travel to a location where reduction occurs. Because oxidation and reduction are involved in the generation of an electric current, redox reactions (Section K) are central to the discussion of electrochemistry. In this chapter we take a closer look at them and see how they and other types of reactions can be used to generate electricity.

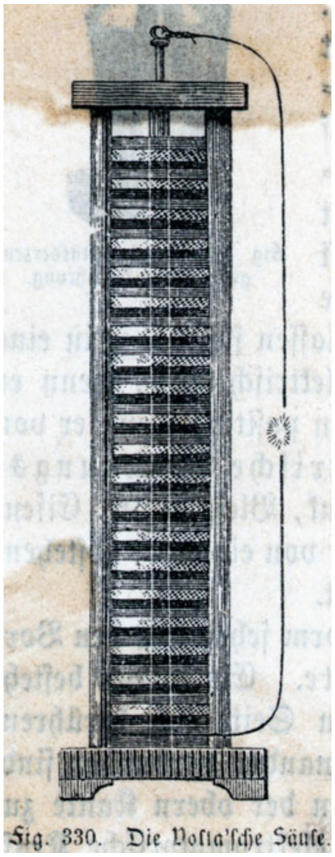

FIGURE 13.1 Volta used this stack of alternating disks of two different metals separated by paper soaked in salt water to produce the first sustained electric current.

For a quantitative discussion of redox reactions we need to be able to write balanced chemical equations. Some redox reactions can be tricky to balance, and special techniques, which we describe in Sections 13.1 and 13.2, have been developed to simplify the procedure.

The chapter begins with a review of redox reactions, which are particularly important for understanding the chemical production of electricity, a topic that occupies the major part of this chapter. Redox reactions are also important in the final part of the chapter, which discusses the use of electricity to bring about chemical reactions.

13.1 Half-Reactions

The key to writing and balancing equations for redox reactions is to think of the reduction and oxidation processes separately. We saw in Section K that oxidation is the loss of electrons and reduction the gain of electrons.

A **half-reaction** is the oxidation or reduction part of a reaction considered alone. An oxidation half-reaction shows the removal of electrons from a species that is being oxidized in a redox reaction. For example, Volta used silver and zinc plates in one of his voltaic piles to carry out the reaction

$$Zn(s) + 2\,Ag^+(aq) \longrightarrow Zn^{2+}(aq) + 2\,Ag(s)$$

To show the oxidation of zinc explicitly we write

$$Zn(s) \longrightarrow Zn^{2+}(s) + 2\,e^-$$

An oxidation half-reaction is a *conceptual* way of reporting an oxidation: the electrons are never actually free. In an equation for an oxidation half-reaction, the electrons released always appear on the right of the arrow. Their state is not given, because they are in transit and do not have a definite physical state. The reduced and oxidized species in a half-reaction jointly form a **redox couple.** In this example, the redox couple consists of Zn^{2+} and Zn, and is denoted Zn^{2+}/Zn. A redox couple has the form Ox/Red, where Ox is the oxidized form of the species and Red is the reduced form.

A note on good practice: Distinguish a conceptual half-reaction from an actual ionization, where the electron is removed and which we would write, for example, as $Na(g) \longrightarrow Na^+(g) + e^-(g)$, with the state of the electron specified.

Now consider reduction. To show the addition of electrons to a species, we write the corresponding half-reaction for electron gain. For example, to show the reduction of Ag^+ ions to Ag metal we write

$$Ag^+(aq) + e^- \longrightarrow Ag(s)$$

This half-reaction, too, is conceptual: the electrons are not actually free. In the equation for a reduction half-reaction, the electrons gained always appear on the left of the arrow. In this example, the redox couple is Ag^+/Ag.

Half-reactions express the two contributions (oxidation and reduction) to an overall redox reaction.

13.2 Balancing Redox Equations

In redox reactions, it is conventional to write H^+ rather than H_3O^+.

Balancing the chemical equation for a redox reaction by inspection can be a real challenge, especially for one taking place in aqueous solution, when water may participate and we must include H_2O and either H^+ or OH^-. In such cases, it is easier to simplify the equation by separating it into its reduction and oxidation half-reactions, balance the half-reactions separately, and then add them together to obtain the balanced equation for the overall reaction. When adding the equations for half-reactions, we match the number of electrons released by oxidation with the number used in reduction, because electrons are neither created nor destroyed in chemical reactions. The procedure is outlined in Toolbox 13.1 and illustrated in Examples 13.1 and 13.2.

TOOLBOX 13.1 HOW TO BALANCE COMPLICATED REDOX EQUATIONS

CONCEPTUAL BASIS

When balancing redox equations, we express the gain of electrons (reduction) and the loss of electrons (oxidation) as separate half-reactions, and then balance both atoms and charge in each of the two half-reactions. When we combine the half-reactions, the number of electrons released in the oxidation must equal the number used in the reduction.

PROCEDURE

In general, first balance the half-reactions separately, then combine them.

Step 1 Identify the species being oxidized and the species being reduced from the changes in their oxidation numbers.
Step 2 Write the two skeletal (unbalanced) equations for the oxidation and reduction half-reactions.
Step 3 Balance all elements in the half-reactions except O and H.
Step 4 In acidic solution, balance O by using H_2O and then balance H by using H^+. In basic solution, balance O by using H_2O; then balance H by adding H_2O to the side of each half-reaction that needs H and adding OH^- to the other side.

When we add . . . OH^- . . . $\longrightarrow$ . . . H_2O . . . to a half-reaction, we are effectively adding one H atom to the right. When we add . . . H_2O . . . $\longrightarrow$ . . . OH^- . . . , we are effectively adding one H atom to the left. Note that one H_2O molecule is added for each H atom needed. If necessary, cancel like species on opposite sides of the arrow.

Step 5 Balance the electric charges by adding electrons to the left for reductions and to the right for oxidations until the charges on the two sides of the arrow are the same.
Step 6 If necessary, multiply each half-reaction by the factor required to give equal numbers of electrons in the two half-reactions, and then add the two equations and include physical states. In some cases it is possible to simplify the half-reactions before they are combined.

Finally, simplify the appearance of the complete equation by canceling species that appear on both sides of the arrow and check to make sure that charges as well as numbers of atoms balance.

Examples 13.1 and 13.2 illustrate this procedure.

EXAMPLE 13.1 Balancing a redox equation in acidic solution

Permanganate ions, MnO_4^-, react with oxalic acid, $H_2C_2O_4$, in acidic aqueous solution, producing manganese(II) ions and carbon dioxide. The skeletal equation (with states added) is

$$MnO_4^-(aq) + H_2C_2O_4(aq) \longrightarrow Mn^{2+}(aq) + CO_2(g)$$

Balance the net ionic equation for this reaction.

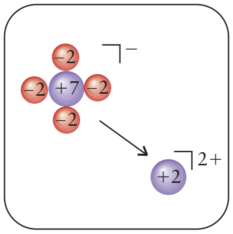
PLAN To balance the equation, work through the procedure for an acidic solution set out in Toolbox 13.1.

SOLVE

Reduction half-reaction:

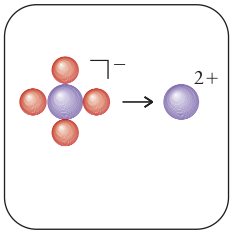
Step 1 Identify the species being reduced.

The oxidation number of Mn decreases from +7 to +2, so the Mn in the MnO_4^- ion is reduced.



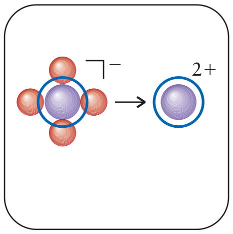
Step 2 Write the skeletal equation for reduction.

$$MnO_4^- \longrightarrow Mn^{2+}$$



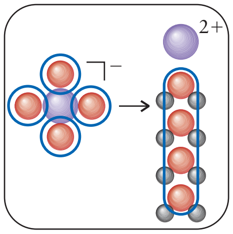
Step 3 Balance all elements except H and O.

$$MnO_4^- \longrightarrow Mn^{2+}$$



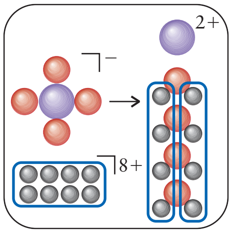
Step 4 Balance the O atoms by adding H_2O.

$$MnO_4^- \longrightarrow Mn^{2+} + 4\,H_2O$$



Balance the H atoms by adding H^+.

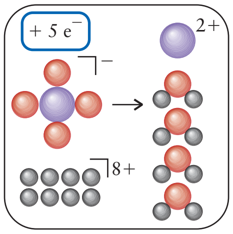
$$MnO_4^- + 8\,H^+ \longrightarrow Mn^{2+} + 4\,H_2O$$



Step 5 Balance the net charges by adding electrons.

Net charge on the left is +7 and on the right +2; we need 5 electrons on the left to bring it to +2.

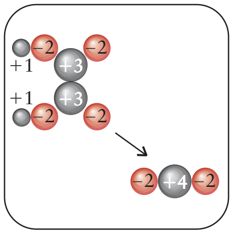
$$MnO_4^- + 8\,H^+ + 5\,e^- \longrightarrow Mn^{2+} + 4\,H_2O$$



Oxidation half-reaction:

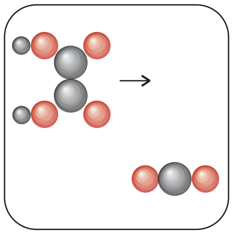
Step 1 Identify the species being oxidized.

The oxidation number of carbon increases from +3 to +4, so the C atoms in the oxalic acid are oxidized.



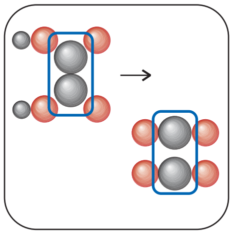
Step 2 Write the skeletal equation for the species being oxidized.

$$H_2C_2O_4 \longrightarrow CO_2$$



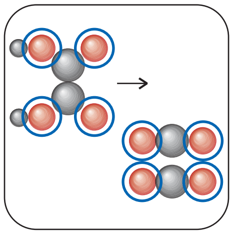
Step 3 Balance all elements except H and O.

$$H_2C_2O_4 \longrightarrow 2\,CO_2$$



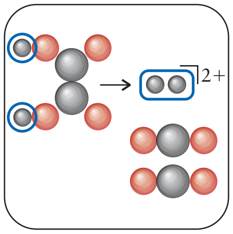
Step 4 Balance the O atoms by adding H_2O (none required).

$$H_2C_2O_4 \longrightarrow 2\ CO_2$$



Balance the H atoms by adding H^+.

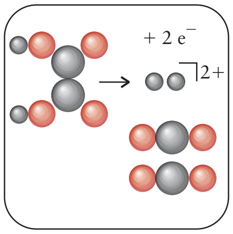
$$H_2C_2O_4 \longrightarrow 2\ CO_2 + 2\ H^+$$



Step 5 Balance the net charges by adding electrons.

Net charge on the left is 0 and on the right +2; we need 2 electrons on the right to bring it to 0.

$$H_2C_2O_4 \longrightarrow 2\ CO_2 + 2\ H^+ + 2\ e^-$$



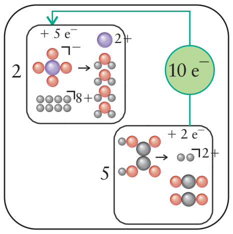
A note on good practice: At this point, check that the number of electrons lost or gained in each half-reaction is the same as the change in oxidation number of the element oxidized or reduced.

Now bring the two half-reactions together.

Step 6 Write the overall equation. First, balance electrons.

Five electrons are gained in one half-reaction and two lost in the other, so we need 10 in each half-reaction. Multiply the reduction half-reaction by 2 and multiply the oxidation half-reaction by 5.

$$2\ MnO_4^- + 16\ H^+ + 10\ e^- \longrightarrow 2\ Mn^{2+} + 8\ H_2O$$
$$5\ H_2C_2O_4 \longrightarrow 10\ CO_2 + 10\ H^+ + 10\ e^-$$



Add the equations and cancel electrons.

$$2\ MnO_4^- + 5\ H_2C_2O_4 + 16\ H^+ \longrightarrow 2\ Mn^{2+} + 8\ H_2O + 10\ CO_2 + 10\ H^+$$

Cancel 10 H^+ ions on each side and include physical states.

$$2\ MnO_4^-(aq) + 5\ H_2C_2O_4(aq) + 6\ H^+(aq) \longrightarrow 2\ Mn^{2+}(aq) + 8\ H_2O(l) + 10\ CO_2(g)$$

Self-Test 13.1A Copper reacts with dilute nitric acid to form copper(II) nitrate and the gas nitric oxide, NO. Write the net ionic equation for the reaction.

[***Answer:*** $3\ Cu(s) + 2\ NO_3^-(aq) + 8\ H^+(aq) \longrightarrow 3\ Cu^{2+}(aq) + 2\ NO(g) + 4\ H_2O(l)$]

Self-Test 13.1B Acidified potassium permanganate solution reacts with sulfurous acid, $H_2SO_3(aq)$, to form sulfuric acid and manganese(II) ions. Write the net ionic equation for the reaction. In acidic aqueous solution, H_2SO_3 is present as electrically neutral molecules and sulfuric acid is present as HSO_4^- ions.

EXAMPLE 13.2 **Balancing a redox equation in basic solution**

The products of the reaction between bromide ions and permanganate ions, MnO_4^-, in basic aqueous solution are solid manganese(IV) oxide, MnO_2, and bromate ions. Balance the net ionic equation for the reaction.

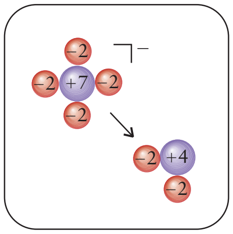
PLAN Work through the procedure for a basic solution set out in Toolbox 13.1.

SOLVE

Reduction half-reaction:

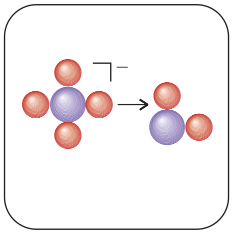
Step 1 Identify the species being reduced.

The oxidation number of Mn changes from +7 in MnO_4^- to +4 in MnO_2, so the Mn in MnO_4^- is reduced.



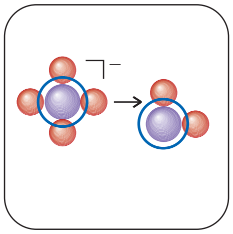
Step 2 Write the skeletal equation for reduction.

$$MnO_4^- \longrightarrow MnO_2$$



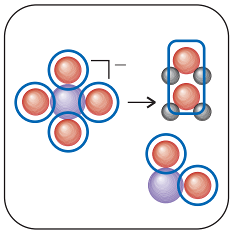
Step 3 The Mn atoms are balanced.

$$MnO_4^- \longrightarrow MnO_2$$



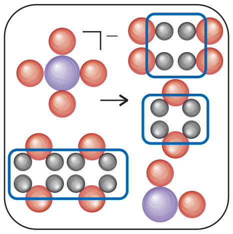
Step 4 Balance the O atoms by adding H_2O.

$$MnO_4^- \longrightarrow MnO_2 + 2\,H_2O$$



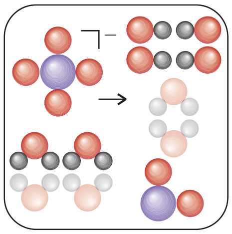
Balance the H atoms by adding (for each H atom needed) one H_2O molecule to the side of each equation that needs hydrogen and one OH^- ion to the opposite side. Here, four H atoms are needed on the left side.

$$MnO_4^- + 4\,H_2O \longrightarrow MnO_2 + 2\,H_2O + 4\,OH^-$$



Cancel like species on opposite sides of the arrow (in this case, $2\,H_2O$).

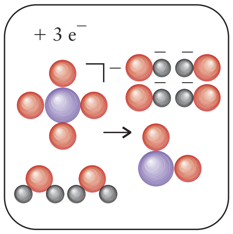
$$MnO_4^- + 2\,H_2O \longrightarrow MnO_2 + 4\,OH^-$$



Step 5 Balance charge by adding electrons.

Net charge on the left is −1 and on the right it is −4; we need 3 electrons on the left to bring it to −4.

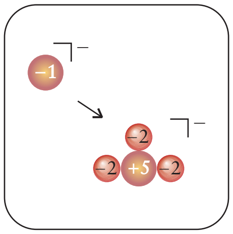
$$MnO_4^- + 2\,H_2O + 3\,e^- \longrightarrow MnO_2 + 4\,OH^-$$



Oxidation half-reaction:

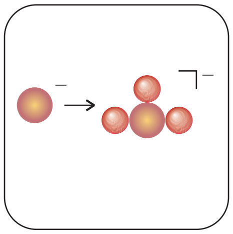
Step 1 Identify the species being oxidized.

The oxidation number of Br increases from −1 in Br^- to +5 in BrO_3^-, and so Br^- is oxidized.



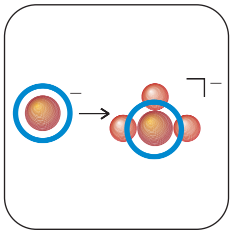
Step 2 Write the skeletal equation for oxidation.

$$Br^- \longrightarrow BrO_3^-$$



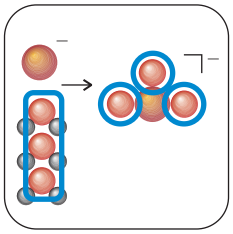
Step 3 The Br atoms are balanced.

$$Br^- \longrightarrow BrO_3^-$$



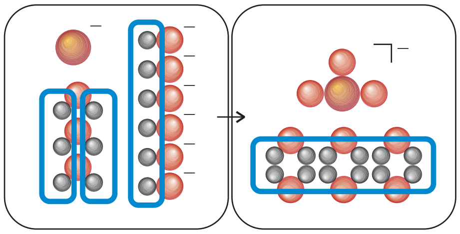
Step 4 Balance the O atoms by adding H_2O.

$$Br^- + 3\,H_2O \longrightarrow BrO_3^-$$



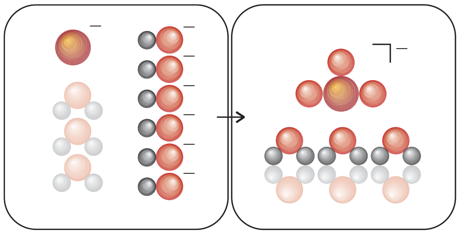
Balance the H atoms by adding (for each H atom needed) one H_2O molecule to the side of each equation that needs hydrogen and one OH^- ion to the opposite side. Here, the right side needs H atoms.

$$Br^- + 3\,H_2O + 6\,OH^- \longrightarrow BrO_3^- + 6\,H_2O$$

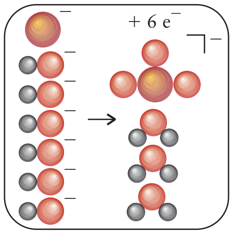


Cancel like species on opposite sides of the arrow (in this case, 3 H_2O).

$$Br^- + 6\,OH^- \longrightarrow BrO_3^- + 3\,H_2O$$



Step 5 Balance charge by adding electrons.



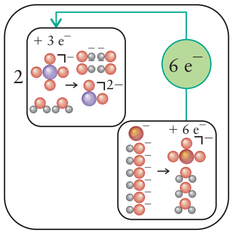
Net charge on the left is −7 and on the right it is −1; we need 6 electrons on the right to bring it to −7.

$$Br^- + 6\,OH^- \longrightarrow BrO_3^- + 3\,H_2O + 6\,e^-$$

A note on good practice: As before, at this point check that the number of electrons lost or gained in each half-reaction is the same as the change in oxidation number of the element oxidized or reduced.

Now bring the two half-reactions together.

Step 6 Write the overall equation.



Because 6 electrons are lost and 3 gained, we need 6 in each half-reaction. Multiply the reduction half-reaction by 2.

$$2\,MnO_4^- + 4\,H_2O + 6\,e^- \longrightarrow 2\,MnO_2 + 8\,OH^-$$

The oxidation half-reaction remains unchanged.

$$Br^- + 6\,OH^- \longrightarrow BrO_3^- + 3\,H_2O + 6\,e^-$$

Add the equations and cancel electrons.

$$2\,MnO_4^- + Br^- + 6\,OH^- + 4\,H_2O \longrightarrow 2\,MnO_2 + BrO_3^- + 8\,OH^- + 3\,H_2O$$

Cancel 3 H_2O and 6 OH^-, then include the physical states.

$$2\,MnO_4^-(aq) + Br^-(aq) + H_2O(l) \longrightarrow 2\,MnO_2(s) + BrO_3^-(aq) + 2\,OH^-(aq)$$

Self-Test 13.2A An alkaline (basic) solution of hypochlorite ions reacts with solid chromium(III) hydroxide to produce aqueous chromate ions and chloride ions. Write the net ionic equation for the reaction.

[***Answer:*** $2\,Cr(OH)_3(s) + 4\,OH^-(aq) + 3\,ClO^-(aq) \longrightarrow 2\,CrO_4^{2-}(aq) + 5\,H_2O(l) + 3\,Cl^-(aq)$]

Self-Test 13.2B When iodide ions react with iodate ions in basic aqueous solution, triiodide ions, I_3^-, are formed. Write the net ionic equation for the reaction. (Note that the same product is obtained in each half-reaction.)

The chemical equation for a reduction half-reaction is added to the equation for an oxidation half-reaction to form the balanced chemical equation for the overall redox reaction.

GALVANIC CELLS

Whenever we turn on a portable media player or a laptop computer, we are completing a circuit that allows a chemical reaction to take place in a battery, a direct descendant of Volta's pile of metals and paper. A battery is an example of an electrochemical cell. In general, an **electrochemical cell** is a device in which an electric current—a flow of electrons through a circuit—is either produced by a spontaneous chemical reaction or used to bring about a nonspontaneous reaction. A **galvanic cell** is an electrochemical cell in which a spontaneous chemical reaction is used to generate an electric current. Technically, a **battery** is a collection of galvanic cells joined in series; so the voltage that it produces—its ability to push an electric current through a circuit—is the sum of the voltages of each cell.

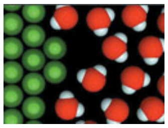
Galvanic cells are also known as *voltaic cells.*

The formal term for "voltage" is "potential difference", measured in volts: $1\,V = 1\,J\cdot C^{-1}$ (see Section 13.4).

13.3 The Structure of Galvanic Cells

To see how a spontaneous reaction can be used to generate an electric current consider the redox reaction between zinc metal and copper(II) ions:

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s) \quad \textbf{(A)}$$



If we were to place a piece of zinc metal into an aqueous copper(II) sulfate solution, we would see a layer of metallic copper begin to deposit on the surface of the zinc (as in Fig. K.5). If we could watch the reaction at the atomic level, we would see that, as the reaction takes place, electrons are transferred from the Zn atoms to adjacent Cu^{2+} ions in the solution. These electrons reduce the Cu^{2+} ions to Cu atoms, which stick to the surface of the zinc or form a finely divided solid deposit in the beaker. The piece of zinc slowly disappears and the blue color of the solution is lost as the Zn atoms give up electrons and form colorless Zn^{2+} ions that drift off into the solution, replacing the Cu^{2+} ions. The Gibbs free energy of the system decreases as electrons are transferred and the reaction approaches equilibrium. However, although energy is released as heat, no electrical work is done.

Now suppose we separate the reactants but provide a pathway for the electrons to travel from the zinc metal to the copper(II) ions. The reaction will still occur, even though the reactants are not in contact. As the reaction proceeds, the electrons can do work—for example, drive an electric motor—as they pass from the species being oxidized to the species being reduced. This process is what happens in a galvanic cell. A galvanic cell consists of two **electrodes,** or metallic conductors, which make electrical contact with the contents of the cell but not with each other, and an **electrolyte**, an ionically conducting medium, inside the cell. In an *ionic conductor* an electric current is carried by the movement of ions. The electrolyte is typically an aqueous solution of an ionic compound. Oxidation takes place at one electrode as the species being oxidized releases electrons into the metallic conductor. Reduction takes place at the other electrode, where the species that is undergoing reduction collects electrons from the metallic conductor (Fig. 13.2). We can think of the overall chemical reaction as pushing electrons on to one electrode from the oxidation process taking place there and pulling them off the other electrode for the reduction taking place at it. This push–pull process sets up a flow of electrons in the external circuit joining the two electrodes, and that current can be used to do electrical work.

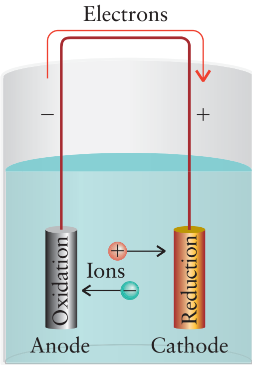


FIGURE 13.2 In an electrochemical cell, a reaction takes place in two separate regions. Oxidation takes place at one electrode (the anode), and the electrons released travel through the external circuit to the other electrode, the cathode, where they cause reduction. The circuit is completed by the ions that carry the electric charge through the solution.

Animation 13.2

The term "electrolyte" was first introduced in Section I to refer to the solute. In the discussion of electrochemical cells, the term is commonly used to refer to the ionically conducting medium, which can be a liquid or solid.

The electrode at which oxidation takes place is called the **anode.** The electrode at which reduction takes place is called the **cathode.** Electrons are released by the oxidation half-reaction at the anode, travel through the external circuit, and reenter the cell at the cathode, where they are used in the reduction half-reaction. A commercial galvanic cell has its cathode marked with a + sign and its anode with a − sign. Think of the + sign as indicating the electrode at which the electrons enter the cell and the − sign as indicating the electrode at which the electrons leave the cell.

The *Daniell cell* is an early example of a galvanic cell that makes use of the oxidation of copper by zinc ions, as in reaction A. The British chemist John Daniell invented it in 1836, when the growth of telegraphy created an urgent need for a cheap, reliable, steady source of electric current. Daniell set up the arrangement shown in Fig. 13.3, in which the two reactants are separated: the zinc metal is immersed in a solution of zinc sulfate and the copper electrode is immersed in a solution of copper(II) sulfate. For the electrons to travel from Zn atoms to Cu^{2+} ions and bring about the spontaneous reaction, they must pass from the zinc metal through the wire that serves as the external circuit, then through the copper electrode into the copper(II) solution. The Cu^{2+} ions are converted into Cu atoms at the cathode by the reduction half-reaction $Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s)$. At the same time zinc atoms are converted into Zn^{2+} ions at the anode by the oxidation half-reaction $Zn(s) \longrightarrow Zn^{2+}(aq) + 2\,e^-$. As Cu^{2+} ions are reduced, the solution at the cathode becomes negatively charged and the solution at the anode begins to develop a positive charge as additional Zn^{2+} ions enter the solution. To prevent this charge buildup, which would quickly stop the flow of electrons, the two solutions are in contact through a porous wall: ions provided by the electrolyte solutions move between the two compartments and complete the electrical circuit.

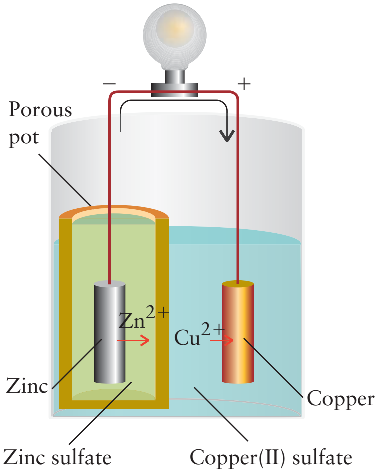

FIGURE 13.3 The Daniell cell consists of copper and zinc electrodes dipping into solutions of copper(II) sulfate and zinc sulfate, respectively. The two solutions make contact through the porous barrier, which allows ions to pass through and complete the electric circuit.

The electrodes in the Daniell cell are made of the metals involved in the reaction. However, not all electrode reactions include a conducting solid as a reactant or product. For example, to use the reduction $2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g)$ at an electrode, a chemically inert metallic conductor, such as an unreactive metal or graphite, must carry the electrons into or out of the electrode compartment. Platinum is customarily used as the electrode for hydrogen: the gas is bubbled over the metal immersed in a solution

that contains hydrogen ions. This arrangement is called a *hydrogen electrode*. The entire compartment with metal conductor and electrolyte solution is commonly referred to as "the electrode" or more formally as a **half-cell.**

In a galvanic cell, a spontaneous chemical reaction draws electrons into the cell through the cathode, the site of reduction, and releases them at the anode, the site of oxidation.

13.4 Cell Potential and Reaction Gibbs Free Energy

A reaction with a lot of pushing-and-pulling power generates a high potential difference (colloquially, a high voltage). A reaction with little pushing-and-pulling power generates only a small potential difference (a low voltage). An exhausted battery is a cell in which the reaction is at equilibrium; it has lost its power to move electrons and has a potential difference of zero. The SI unit of potential (and potential difference) is the **volt** (V). A volt is defined so that a charge of one coulomb (1 C) falling through a potential difference of one volt (1 V) releases one joule (1 J) of energy:

One coulomb is the magnitude of the charge delivered by a current of one ampere flowing for one second: $1\ C = 1\ A{\cdot}s$.

$$1\ V{\cdot}C = 1\ J$$

To express these ideas quantitatively it is helpful to note that electrical potential is analogous to gravitational potential. The maximum work that a falling weight can do is equal to its mass times the difference in gravitational potential. Similarly, the maximum work that an electron can do is equal to its charge times the difference in electrical potential through which it falls. Electrical work is a type of nonexpansion work because it involves moving electrons rather than changing the volume of the system. In Section 8.14 we established that at constant temperature and pressure, the maximum nonexpansion work that a system can do is equal to the change in the Gibbs free energy. We need to bring these two concepts together by finding the relation between the Gibbs free energy of a reaction (a thermodynamic property) and the potential difference (an electrochemical property) produced by that reaction.

HOW DO WE DO THAT?

We established in Section 8.14 (Eq. 21) that the change in Gibbs free energy is the maximum nonexpansion work that a reaction can do at constant pressure and temperature:

$$\Delta G = w_e$$

The work done when an amount n of electrons (in moles) travels through a potential difference E is their total charge times the potential difference. The charge of one electron is $-e$; the charge per mole of electrons is $-eN_A$, where N_A is Avogadro's constant. Therefore, the total charge is $-neN_A$ and the work done is

$$w_e = \text{total charge} \times \text{potential difference} = (-neN_A) \times E$$

Faraday's constant, F, is the magnitude of the charge per mole of electrons (the product of the elementary charge e and Avogadro's constant N_A):

$$F = eN_A = (1.602\,177 \times 10^{-19}\ C) \times \{6.0223 \times 10^{23}\ (\text{mol e}^-)^{-1}\}$$
$$= 9.6485 \times 10^4\ C{\cdot}(\text{mol e}^-)^{-1}$$

Faraday's constant is normally abbreviated to $F = 9.6485 \times 10^4\ C{\cdot}mol^{-1}$ (or $96.485\ kC{\cdot}mol^{-1}$). We can now write the preceding expression for work as

$$w_e = -nFE$$

When this equation is combined with the thermodynamic equation relating Gibbs free energy and nonexpansion work, we obtain

$$\Delta G = -nFE$$

The units of ΔG are joules (or kilojoules), with a value that depends not only on E, but also on the amount n (in moles) of electrons transferred in the reaction. Thus, in reaction A, $n = 2$ mol. As in the discussion of the relation between Gibbs free energy and equilibrium

constants (Section 10.3), we shall sometimes need to use this relation in its "molar" form, with n interpreted as a pure number.

$$\Delta G_r = -nFE$$

The units of ΔG_r are joules (or kilojoules) per mole. The subscript r is always the signal that we are using this "molar" form.

The relation that we have derived,

$$\Delta G = -nFE \quad \textbf{(1a)}$$

relates the thermodynamic information that we have been compiling since Chapter 7 to the electrochemical information in this chapter. When using the molar convention for the reaction Gibbs energy, we add the subscript "r" and write

$$\Delta G_r = -nFE \quad \textbf{(1b)}$$

where n is a pure number with the unit "mol" struck out. We see from this equation that E provides an experimental criterion of spontaneity: if the potential difference is positive, then the reaction Gibbs free energy is negative, and the cell reaction has a spontaneous tendency to form products. If the potential difference is negative, then the *reverse* of the cell reaction is spontaneous, and the cell reaction has a spontaneous tendency to form reactants.

There is a hidden assumption in the derivation of Eq. 1. *Maximum* nonexpansion work is obtained when a cell is operating *reversibly*. Therefore, Eq. 1 applies only when the pushing power of the cell is balanced against an external matching source of potential. In practice, that means using a voltmeter with such a high resistance that the potential difference is measured without drawing any current. The potential difference under these conditions is the *maximum* potential that can be produced. It is called the **cell potential** (which is still widely called the *electromotive force*, emf, of the cell). From now on, E_{cell} will always be taken to represent this potential difference. A *working cell*, one actually producing current, such as the cell in a media player, will produce a potential difference smaller than that predicted by Eq. 1.

Remember the definition of reversibility in Section 7.3, which requires the pushing force of the system to be balanced against an equal and opposite force.

EXAMPLE 13.3 Calculating the reaction Gibbs free energy

The potential of the Daniell cell for certain concentrations of copper and zinc ions is 1.04 V. What is the reaction Gibbs free energy under those conditions?

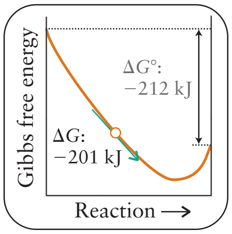
Anticipate Because the cell generates an electric current, we should expect to find that the Gibbs free energy of reaction is negative, corresponding to a spontaneous reaction.

PLAN Use Eq. 1 to determine the reaction Gibbs free energy from the cell potential.

SOLVE From the chemical equation for the cell reaction (reaction A), we see that $n = 2$ mol.

From $\Delta G = -nFE_{cell}$,

$$\Delta G = -(2\ \text{mol}) \times (9.6485 \times 10^4\ \text{C·mol}^{-1}) \times (1.04\ \text{V})$$
$$= -2.01 \times 10^5\ \text{C·V}$$



Evaluate Because 1 C·V = 1 J, we can conclude that the Gibbs free energy of reaction A under these conditions is −201 kJ; because this value is negative, as we expected, the reaction is spontaneous in the forward direction for this composition of the cell.

A note on good practice: The value of n depends on the balanced equation. Check to ensure that n matches the number of moles of electrons transferred in the balanced equation.

Self-Test 13.3A The reaction taking place in a nicad cell is $Cd(s) + 2\,Ni(OH)_3(s) \longrightarrow Cd(OH)_2(s) + 2\,Ni(OH)_2(s)$, and the cell potential when fully charged is 1.25 V. What is the reaction Gibbs free energy? (See Table 13.2.)

[***Answer:*** −241 kJ]

Self-Test 13.3B The reaction taking place in the silver cell used in some cameras and wristwatches is $Ag_2O(s) + Zn(s) \longrightarrow 2\,Ag(s) + ZnO(s)$, and the cell potential when new is 1.6 V. What is the reaction Gibbs free energy? (See Table 13.2.)

We shall often employ Eq. 1 for the *standard* reaction Gibbs free energy, $\Delta G°$, when it becomes

$$\Delta G° = -nFE_{cell}° \qquad (2)^*$$

In this expression, $E_{cell}°$ is the **standard cell potential,** the cell potential measured when all the species taking part are in their standard states. In practice, this condition means that all gases are at 1 bar, all participating solutes are at 1 $mol{\cdot}L^{-1}$, and all liquids and solids are pure. For example, to measure the standard potential of the Daniell cell, we use 1 M $CuSO_4(aq)$ and a pure copper electrode in one electrode compartment and 1 M $ZnSO_4(aq)$ and a pure zinc electrode in the other.

More precisely, all the solutes should be at unit activity, not unit molarity. Activities differ appreciably from molarities in electrolyte solution because ions interact over long distances. However, we ignore this complication here.

The value of E_{cell} is the same, regardless of how we write the equation, but the value of ΔG depends on the stoichiometric coefficients in the chemical equation. When we multiply all the coefficients by 2 the value of ΔG doubles. However, multiplying all the coefficients by 2 also doubles the value of n, and so $E_{cell} = -\Delta G/nF$ remains the same. That is, although the reaction Gibbs free energy changes when the chemical equation is multiplied by a factor, E_{cell} (and its standard value, $E_{cell}°$) does not change:

	$\Delta G°$	$E_{cell}°$
$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)$	−212 kJ	+1.10 V
$2\,Zn(s) + 2\,Cu^{2+}(aq) \longrightarrow 2\,Zn^{2+}(aq) + 2\,Cu(s)$	−424 kJ	+1.10 V

A practical implication of this conclusion is that the cell potential is independent of the size of the cell. To get a higher potential than predicted by Eq. 1, we have to construct a battery by joining cells in series: the potential is then the sum of the potentials of the individual cells (see Section 13.15 for some examples).

Cell potential and reaction Gibbs free energy are related by Eq. 1 ($\Delta G = -nFE_{cell}$), and their standard values are related by Eq. 2 ($\Delta G° = -nFE_{cell}°$). The magnitude of the cell potential is independent of how the chemical equation is written.

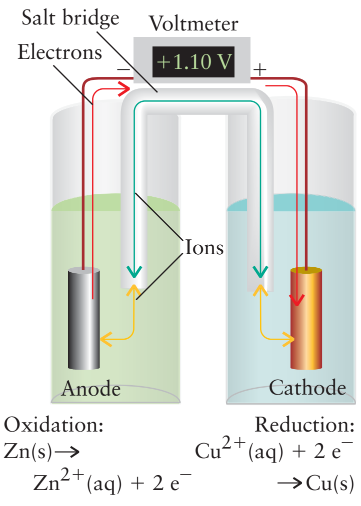


FIGURE 13.4 In a galvanic cell electrons produced by oxidation at the anode (–) travel through the external circuit and reenter the cell at the cathode (+), where they cause reduction. The circuit is completed inside the cell by migration of ions through the salt bridge. When the cell potential is measured, no current actually flows: the voltmeter measures the tendency of the electrons to flow from one electrode to the other.

13.5 The Notation for Cells

Chemists use a special notation to specify the structure of electrode compartments in a galvanic cell. The two electrodes in the Daniell cell, for instance, are denoted $Zn(s)|Zn^{2+}(aq)$ and $Cu^{2+}(aq)|Cu(s)$. Each vertical line represents an interface between phases—in this case, between solid metal and ions in solution in the order reactant|product.

The structure of a cell is expressed in a symbolic **cell diagram,** by using the conventions specified by IUPAC and used by chemists throughout the world. The diagram for the Daniell cell, for instance, is

$$Zn(s)|Zn^{2+}(aq)|Cu^{2+}(aq)|Cu(s)$$

In the Daniell cell, zinc sulfate and copper(II) sulfate solutions meet inside the porous barrier to complete the circuit. However, when different ions mingle together, they can affect the cell voltage. To keep solutions from mixing, chemists use a **salt bridge** to join the two electrode compartments and complete the electrical circuit. A salt bridge typically consists of a gel containing a concentrated aqueous salt solution in an inverted U-tube (Fig. 13.4). The bridge allows a flow of ions, and so it completes the electrical circuit, but the ions are chosen so that they do not affect the cell reaction (often KCl is

used). In a cell diagram, a salt bridge is shown by a double vertical line (‖), and so the arrangement in Fig. 13.4 is denoted

$$\mathrm{Zn(s)|Zn^{2+}(aq)\|Cu^{2+}(aq)|Cu(s)}$$

Thinking point: Are there any salts that you definitely would *not* want to use in a salt bridge?

Any inert metallic component of an electrode is written as the outermost component of that electrode in the cell diagram. For example, a hydrogen electrode constructed with platinum is denoted $\mathrm{H^+(aq)|H_2(g)|Pt(s)}$ when it is the right-hand electrode in a cell diagram and $\mathrm{Pt(s)|H_2(g)|H^+(aq)}$ when it is the left-hand electrode. An electrode consisting of a platinum wire dipping into a solution of iron(II) and iron(III) ions is denoted either $\mathrm{Fe^{3+}(aq), Fe^{2+}(aq)|Pt(s)}$ or $\mathrm{Pt(s)|Fe^{3+}(aq),Fe^{2+}(aq)}$. In this case, the oxidized and reduced species are both in the same phase, and so a comma rather than a line is used to separate them. Pairs of ions in solution are normally written in the order Ox,Red.

When it is important to emphasize the spatial arrangement of an electrode, the order may reflect that arrangement, as in $\mathrm{Cl^-(aq)|Cl_2(g)|Pt(s)}$.

Self-Test 13.4A Write the diagram for a cell with a hydrogen electrode on the left and an iron(III)/iron(II) electrode on the right. The two electrode compartments are connected by a salt bridge and platinum is used as the conductor at each electrode.

[***Answer:*** $\mathrm{Pt(s)|H_2(g)|H^+(aq)\|Fe^{3+}(aq),Fe^{2+}(aq)|Pt(s)}$]

Self-Test 13.4B Write the diagram for a cell that has an electrode consisting of a manganese wire dipping into a solution of manganese(II) ions on the left, a salt bridge, and a copper(II)/copper(I) electrode on the right with a platinum wire.

As already remarked, the cell potential is measured with an electronic voltmeter (Fig. 13.5), and we identify the cathode by noting which terminal of the cell is positive. If the cathode is the electrode that we have placed on the right of the cell diagram, then by convention the cell potential is reported as positive, as in

Formerly, cell potentials were measured with a device called a potentiometer, but electronic devices are more reliable and easier to interpret.

electrons (→)

$$\mathrm{Zn(s)|Zn^{2+}(aq)\|Cu^{2+}(aq)|Cu(s)} \qquad E_{\mathrm{cell}} = +1.10\ \mathrm{V}$$

Anode (−) Cathode (+)

(The cell potential depends on the concentrations of the ions, as we explore later; here we have reported the value observed when the two solutions have equal cation concentrations.) In this case, the electrons can be thought of as tending to travel through the external circuit from the left of the cell as written (the anode) to the right (the cathode). However, if the cathode is found to be the electrode that we have written on the left of the cell diagram, then the cell potential is reported as negative, as in

electrons (←)

$$\mathrm{Cu(s)|Cu^{2+}(aq)\|Zn^{2+}(aq)|Zn(s)} \qquad E_{\mathrm{cell}} = -1.10\ \mathrm{V}$$

Cathode (+) Anode (−)

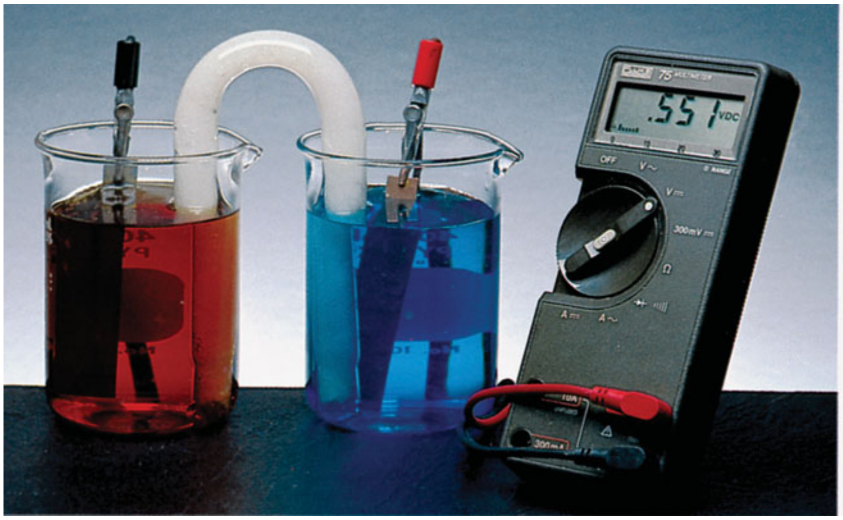

FIGURE 13.5 The cell potential is measured with an electronic voltmeter, a device designed to draw negligible current so that the composition of the cell does not change during the measurement. The display shows a positive value when the + terminal of the meter is connected to the cathode of the galvanic cell, which is also a + terminal. The salt bridge completes the electric circuit within the cell.

Lab Video 13.5

In summary, the sign of the cell potential reported in conjunction with a cell diagram is the same as the sign of the right-hand electrode in the diagram:

- A positive cell potential indicates that the right-hand electrode in the cell diagram is the cathode.
- A negative cell potential indicates that the right-hand electrode in the cell diagram is the anode.

A particular cell diagram corresponds to a specific direction of writing the corresponding cell reaction. *Solely for the purpose of writing the cell reaction corresponding to a given cell diagram*, we suppose that the right-hand electrode in the diagram is the site of reduction and that the left-hand electrode is the site of oxidation, and write the corresponding half-reactions. Thus, for the cell written as $Zn(s)|Zn^{2+}(aq)||Cu^{2+}(aq)|Cu(s)$, we write

$Zn(s)|Zn^{2+}(aq)||Cu^{2+}(aq)|Cu(s)$

Left (L)	Right (R)
$Zn(s) \longrightarrow Zn^{2+}(aq) + 2\,e^-$	$Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s)$
(oxidation)	(reduction)

Overall (R + L): $Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)$ $\quad E_{cell} = +1.10\text{ V}$

Because $E_{cell} > 0$, and therefore $\Delta G < 0$ for this reaction, the cell reaction as written is spontaneous for the concentrations of ions that we chose. For the alternative way of writing the cell diagram, $Cu(s)|Cu^{2+}(aq)||Zn^{2+}(aq)|Zn(s)$, we would have

$Cu(s)|Cu^{2+}(aq)||Zn^{2+}(aq)|Zn(s)$

Left (L)	Right (R)
$Cu(s) \longrightarrow Cu^{2+}(aq) + 2\,e^-$	$Zn^{2+}(aq) + 2\,e^- \longrightarrow Zn(s)$
(oxidation)	(reduction)

Overall (L + R): $Zn^{2+}(aq) + Cu(s) \longrightarrow Zn(s) + Cu^{2+}(aq)$ $\quad E_{cell} = -1.10\text{ V}$

Because $E_{cell} < 0$, and therefore $\Delta G > 0$, the *reverse* of the cell reaction as written is spontaneous for the chosen concentrations of ions.

The general procedure for writing the chemical equation for the reaction corresponding to a given cell diagram is set out in Toolbox 13.2.

TOOLBOX 13.2 HOW TO WRITE A CELL REACTION CORRESPONDING TO A CELL DIAGRAM

CONCEPTUAL BASIS

A cell diagram corresponds to a specific cell reaction in which the right-hand electrode in the cell diagram is treated as the site of reduction and the left-hand electrode is treated as the site of oxidation. The sign of the cell potential then distinguishes whether the resulting reaction is spontaneous in the direction written ($E > 0$) or whether the reverse reaction is spontaneous ($E < 0$).

PROCEDURE

Step 1 Write the equation for the electrode on the right of the cell diagram as a reduction half-reaction (remember: **R**ight for **R**eduction).

Step 2 Write the equation for the electrode on the left of the cell diagram as an oxidation half-reaction.

Step 3 Multiply one or both equations by a factor if necessary to equalize the number of electrons, and then add the two equations.

If the cell potential is positive, then the reaction is spontaneous as written. If the cell potential is negative, then the reverse reaction is spontaneous.

This procedure is illustrated in Example 13.4.

EXAMPLE 13.4 Writing a cell reaction

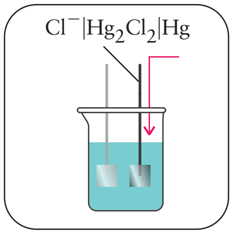
Write the reaction for the cell $Pt(s)|H_2(g)|HCl(aq)|Hg_2Cl_2(s)|Hg(l)$.

PLAN Follow the procedure set out in Toolbox 13.2.

SOLVE

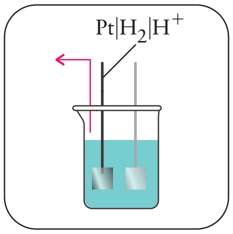
Step 1 Write the equation for the reduction at the right-hand electrode.

$$Hg_2Cl_2(s) + 2\,e^- \longrightarrow 2\,Hg(l) + 2\,Cl^-(aq)$$



Step 2 Write the equation for the oxidation at the left-hand electrode.

$$\tfrac{1}{2}\,H_2(g) \longrightarrow H^+(aq) + e^-$$

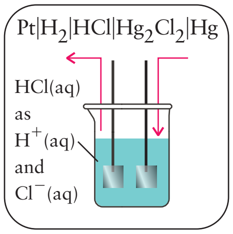


Step 3 To balance electrons, multiply the oxidation half-reaction by 2.

$$H_2(g) \longrightarrow 2\,H^+(aq) + 2\,e^-$$

Add the half-reactions together.

$$Hg_2Cl_2(s) + H_2(g) \longrightarrow 2\,Hg(l) + 2\,Cl^-(aq) + 2\,H^+(aq)$$



If the concentrations in the cell are such that it is reported as having a positive potential (that is, the mercury/mercury(I) chloride electrode is found to be positive), then mercury(I) ions are being reduced and the reaction is spontaneous as written. If the concentrations are such that the potential is found to be negative (that is, the hydrogen electrode is found to be positive), then the reverse of the reaction that we have derived would be spontaneous.

Self-Test 13.5A (a) Write the chemical equation for the reaction corresponding to the cell $Pt(s)|H_2(g)|H^+(aq)\|Co^{3+}(aq),Co^{2+}(aq)|Pt(s)$. (b) Given that the cell potential is positive, is the cell reaction spontaneous as written?

[***Answer:*** (a) $H_2(g) + 2\,Co^{3+}(aq) \longrightarrow 2\,H^+(aq) + 2\,Co^{2+}(aq)$; (b) yes]

Self-Test 13.5B (a) Write the chemical equation for the reaction corresponding to the cell $Hg(l)|Hg_2Cl_2(s)|HCl(aq)\|Hg_2(NO_3)_2(aq)|Hg(l)$. (b) Given that the cell potential is positive, is the cell reaction spontaneous as written?

An electrode is designated by representing the interfaces between phases by a vertical line. A cell diagram depicts the physical arrangement of species and interfaces, with any salt bridge denoted by a double vertical line. The sign with which the cell potential is reported is the same as the measured sign of the right-hand electrode in the cell diagram. A positive cell potential indicates that the cell reaction is spontaneous as written.

13.6 Standard Potentials

There are thousands of possible galvanic cells that can be studied. However, instead of having to learn about all these different cells, it is much simpler to learn about the smaller number of electrodes that are combined to form the cells. Under standard conditions (all solutes present at 1 mol·L^{-1}; all gases at 1 bar), we can think of each electrode as making a characteristic contribution to the cell potential called its **standard potential**, $E°$. Each standard potential is a measure of the electron-pulling power of a single electrode. In a galvanic cell, the electrodes pull in opposite directions, so the

Standard potentials are also called *standard electrode potentials.* Because they are always written for reduction half-reactions, they are also sometimes called *standard reduction potentials.*

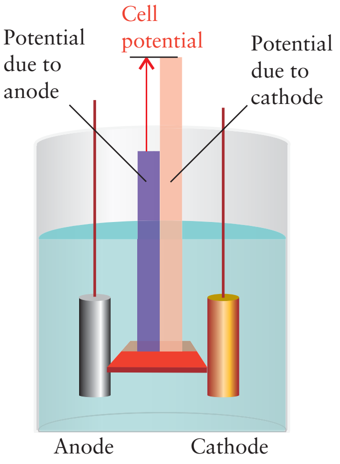


FIGURE 13.6 The cell potential can be thought of as the difference of the two potentials produced by the two electrodes.

overall pulling power of the cell, the cell's standard potential, is the *difference* of the standard potentials of the two electrodes (Fig. 13.6). That difference is always written as

$$E_{cell}° = E°(\text{electrode on right of cell diagram}) - E°(\text{electrode on left of cell diagram}) \quad \textbf{(3a)}$$

or, more succinctly,

$$E_{cell}° = E_R° - E_L° \quad \textbf{(3b)}$$

If $E_{cell}° > 0$, then the corresponding cell reaction is spontaneous under standard conditions (that is, as explained in Section 10.3, $K > 1$ for the reaction) and the electrode on the right of the cell diagram serves as the cathode. For example, for the cell

$$Fe(s)|Fe^{2+}(aq)\|Ag^{+}(aq)|Ag(s), \quad \text{corresponding to } 2\,Ag^{+}(aq) + Fe(s) \longrightarrow 2\,Ag(s) + Fe^{2+}(aq)$$

we write

$$E_{cell}° = E°(Ag^{+}/Ag) - E°(Fe^{2+}/Fe)$$

and find $E_{cell}° = +\,1.24$ V at 25°C. Because $E_{cell}° > 0$, the cell reaction has $K > 1$, with products dominant at equilibrium, and iron metal can reduce silver ions. If we had written the cell in the opposite order,

$$Ag(s)|Ag^{+}(aq)\|Fe^{2+}(aq)|Fe(s), \quad \text{corresponding to } 2\,Ag(s) + Fe^{2+}(aq) \longrightarrow Ag^{+}(aq) + Fe(s)$$

we would have written

$$E_{cell}° = E°(Fe^{2+}/Fe) - E°(Ag^{+}/Ag)$$

and would have found $E_{cell}° = -1.24$ V. We would report that for this reaction $K < 1$, with reactants dominant at equilibrium. However, the conclusion is the same: iron has a tendency to reduce silver.

A note on good practice: Although $E_{cell}° > 0$ is often said to signify a spontaneous reaction, it actually signifies that the reaction is spontaneous only when the reactants and products all have their standard values. At other compositions, the reverse reaction might be spontaneous. It is much better to regard $E_{cell}° > 0$ as signifying that $K > 1$ for the reaction and $E_{cell}° < 0$ as signifying that $K < 1$, because the equilibrium constant is a fixed characteristic of the reaction. Whether or not the forward reaction is positive then depends on the relative sizes of Q and K, as explained in Chapter 10.

A problem with compiling a list of standard potentials is that we know only the *overall* cell potential, not the contribution of a single electrode. A voltmeter placed between the two electrodes of a galvanic cell measures the *difference* of their potentials, not the individual values. To provide numerical values for individual standard potentials, we arbitrarily set the standard potential of one particular electrode, the hydrogen electrode, equal to zero at all temperatures:

$$2\,H^{+}(g) + 2\,e^{-} \longrightarrow H_2(g) \qquad E° = 0$$

In redox couple notation, $E°(H^{+}/H_2) = 0$ at all temperatures. A hydrogen electrode in its standard state, with hydrogen gas at 1 bar and the hydrogen ions present at 1 mol·L^{-1} (strictly, unit activity), is called a **standard hydrogen electrode** (SHE). The standard hydrogen electrode is then used to define the standard potentials of all other electrodes:

> The standard potential of a couple is the standard potential of a cell (including the sign) in which the couple forms the right-hand electrode in the cell diagram and a hydrogen electrode forms the left-hand electrode in the cell diagram.

For example, for the cell

$$Pt(s)|H_2(g)|H^{+}(aq)\|Cu^{2+}(aq)|Cu(s)$$

we find that the standard cell potential is 0.34 V with the copper electrode the cathode, and so $E_{cell}° = +0.34$ V. Because the hydrogen electrode contributes zero to the standard cell potential, the cell potential is attributed entirely to the copper electrode, and we write

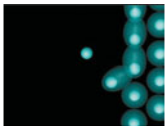
$$Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s) \qquad E°(Cu^{2+}/Cu) = +0.34\text{ V}$$

The standard potential of an electrode is a measure of the tendency of the associated half-reaction to occur relative to the reduction of H^+ ions. For example, because the cell reaction

$$Cu^{2+}(aq) + H_2(g) \longrightarrow Cu(s) + 2\,H^+(aq)$$

has $K > 1$ (because $E_{cell}° > 0$), we can consider the oxidizing ability of $Cu^{2+}(aq)$, as represented by the reduction half-reaction $Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s)$, to be greater than the oxidizing ability of $H^+(aq)$, as represented by $2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g)$. Consequently, Cu^{2+} ions can be reduced to metallic copper by hydrogen gas, in the sense that $K > 1$ for the reaction. In general (Fig. 13.7):

> The more *positive* the potential, the greater the electron-pulling power of the reduction half-reaction and, therefore, the more strongly *oxidizing* the redox couple (the stronger the tendency for the half-reaction to occur as a reduction).



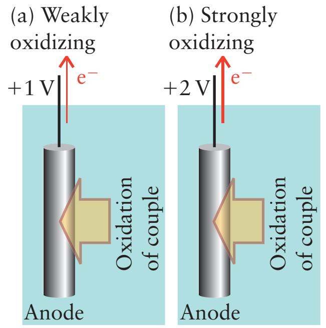


FIGURE 13.7 (a) A couple that has a small positive potential has only a small tendency to be reduced and so has a weak electron-pulling power (is a weak acceptor of electrons) relative to hydrogen ions; hence it is a weak oxidizing agent. (b) A couple with a high positive potential has strong pulling power (is a strong acceptor of electrons) and is a strong oxidizing agent.

Animation 13.7

Now consider the cell

$$Pt(s)|H_2(g)|H^+(aq)\|Zn^{2+}(aq)|Zn(s)$$

and the corresponding cell reaction

$$Zn^{2+}(aq) + H_2(g) \longrightarrow Zn(s) + 2\,H^+(aq)$$

The magnitude of the standard cell potential is 0.76 V, but in this case the hydrogen electrode is found to be the cathode: therefore, the standard cell potential is reported as -0.76 V. Because the entire potential is attributed to the zinc electrode, we write

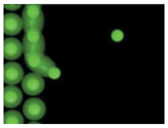
$$Zn^{2+}(aq) + 2\,e^- \longrightarrow Zn(s) \qquad E°(Zn^{2+}/Zn) = -0.76\text{ V}$$

The negative standard potential means that the Zn^{2+}/Zn electrode is the anode in a cell with H^+/H_2 as the other electrode and, therefore, that the *reverse* of the cell reaction, specifically

$$Zn(s) + 2\,H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2(g)$$

has $E_{cell}° > 0$ and therefore $K > 1$. We can conclude that the reducing ability of Zn(s) in the half-reaction $Zn(s) \longrightarrow Zn^{2+}(aq) + 2\,e^-$ is greater than the reducing ability of $H_2(g)$ in the half-reaction $H_2(g) \longrightarrow 2\,H^+(aq) + 2\,e^-$. Consequently, zinc metal can reduce H^+ ions in acidic solution to hydrogen gas under standard conditions. In general (Fig. 13.8):

> The more *negative* the potential, the greater the electron-donating power of the oxidation half-reaction and therefore the more strongly *reducing* the redox couple (that is, the stronger the tendency for the half-reaction to occur as an oxidation).



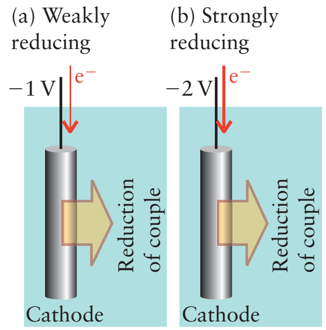


FIGURE 13.8 (a) A couple that has a small negative potential has only a small tendency to be oxidized and so has a poor pushing power (is a weak donor of electrons) relative to hydrogen; hence it is a weak reducing agent. (b) A couple with a large negative potential has strong pushing power (is a strong donor of electrons) and is a strong reducing agent.

Animation 13.8

Table 13.1 lists a number of standard electrode potentials measured at 25°C (the only temperature we consider here); a longer list can be found in Appendix 2B. The standard potentials of elements vary in a complicated way through the periodic table (Fig. 13.9). However, the most negative—the most strongly reducing—are usually found toward the left of the periodic table, and the most positive—the most strongly oxidizing—are found toward the upper right.

In Appendix 2B, standard potentials are listed both by numerical value and alphabetically, to make it easy to find the one you want.

EXAMPLE 13.5 Determining the standard potential of an electrode

The standard potential of a zinc electrode is -0.76 V, and the standard potential of the cell

$$Zn(s)|Zn^{2+}(aq)\|Sn^{4+}(aq), Sn^{2+}(aq)|Pt(s)$$

is $+0.91$ V. What is the standard potential of the Sn^{4+}/Sn^{2+} electrode?

TABLE 13.1 Standard Potentials at 25°C*

Species	Reduction half-reaction	$E°$ (V)
Oxidized form is strongly oxidizing		
F_2/F^-	$F_2(g) + 2\,e^- \longrightarrow 2\,F^-(aq)$	+2.87
Au^+/Au	$Au^+(aq) + e^- \longrightarrow Au(s)$	+1.69
Ce^{4+}/Ce^{3+}	$Ce^{4+}(aq) + e^- \longrightarrow Ce^{3+}(aq)$	+1.61
$MnO_4^-,H^+/Mn^{2+},H_2O$	$MnO_4^-(aq) + 8\,H^+(aq) + 5\,e^- \longrightarrow Mn^{2+}(aq) + 4\,H_2O(l)$	+1.51
Cl_2/Cl^-	$Cl_2(g) + 2\,e^- \longrightarrow 2\,Cl^-(aq)$	+1.36
$Cr_2O_7^{2-},H^+/Cr^{3+},H_2O$	$Cr_2O_7^{2-}(aq) + 14\,H^+(aq) + 6\,e^- \longrightarrow 2\,Cr^{3+}(aq) + 7\,H_2O(l)$	+1.33
$O_2,H^+/H_2O$	$O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l)$	+1.23; +0.82 at pH = 7
Br_2/Br^-	$Br_2(l) + 2\,e^- \longrightarrow 2\,Br^-(aq)$	+1.09
$NO_3^-,H^+/NO,H_2O$	$NO_3^-(aq) + 4\,H^+(aq) + 3\,e^- \longrightarrow NO(g) + 2\,H_2O(l)$	+0.96
Ag^+/Ag	$Ag^+(aq) + e^- \longrightarrow Ag(s)$	+0.80
Fe^{3+}/Fe^{2+}	$Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq)$	+0.77
I_2/I^-	$I_2(s) + 2\,e^- \longrightarrow 2\,I^-(aq)$	+0.54
$O_2,H_2O/OH^-$	$O_2(g) + 2\,H_2O(l) + 4\,e^- \longrightarrow 4\,OH^-(aq)$	+0.40; +0.82 at pH = 7
Cu^{2+}/Cu	$Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s)$	+0.34
$AgCl/Ag,Cl^-$	$AgCl(s) + e^- \longrightarrow Ag(s) + Cl^-(aq)$	+0.22
H^+/H_2	$2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g)$	0, by definition
Fe^{3+}/Fe	$Fe^{3+}(aq) + 3\,e^- \longrightarrow Fe(s)$	−0.04
$O_2,H_2O/HO_2^-,OH^-$	$O_2(g) + H_2O(l) + 2\,e^- \longrightarrow HO_2^-(aq) + OH^-(aq)$	−0.08
Pb^{2+}/Pb	$Pb^{2+}(aq) + 2\,e^- \longrightarrow Pb(s)$	−0.13
Sn^{2+}/Sn	$Sn^{2+}(aq) + 2\,e^- \longrightarrow Sn(s)$	−0.14
Fe^{2+}/Fe	$Fe^{2+}(aq) + 2\,e^- \longrightarrow Fe(s)$	−0.44
Zn^{2+}/Zn	$Zn^{2+}(aq) + 2\,e^- \longrightarrow Zn(s)$	−0.76
$H_2O/H_2,OH^-$	$2\,H_2O(l) + 2\,e^- \longrightarrow H_2(g) + 2\,OH^-(aq)$	−0.83; −0.42 at pH = 7
Al^{3+}/Al	$Al^{3+}(aq) + 3\,e^- \longrightarrow Al(s)$	−1.66
Mg^{2+}/Mg	$Mg^{2+}(aq) + 2\,e^- \longrightarrow Mg(s)$	−2.36
Na^+/Na	$Na^+(aq) + e^- \longrightarrow Na(s)$	−2.71
K^+/K	$K^+(aq) + e^- \longrightarrow K(s)$	−2.93
Li^+/Li	$Li^+(aq) + e^- \longrightarrow Li(s)$	−3.05
Reduced form is strongly reducing		

*For a more extensive table, see Appendix 2B.

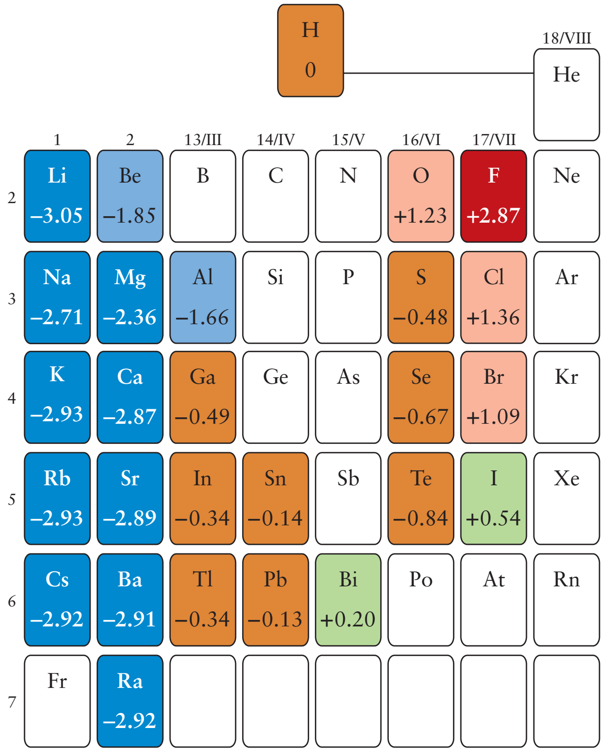

FIGURE 13.9 The variation of standard potentials through the main groups of the periodic table. Note that the most negative values are in the s block and that the most positive values are close to fluorine.

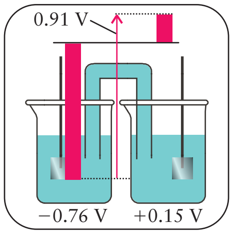
Anticipate Because the cell potential is positive, the cell reaction is spontaneous as written under standard conditions, which means that the right hand electrode (tin) will act as the cathode. Therefore, tin(IV) has a stronger potential to be reduced than zinc and we should expect that the standard potential of the Sn^{4+}/Sn^{2+} electrode will be more positive than that of zinc.

PLAN To determine the standard potential of an electrode from the potential of a standard cell in which the other electrode has a known standard potential, we use Eq. 3 rearranged into $E_R° = E_{cell}° + E_L°$.

SOLVE

From Eq. 3, $E_{cell}° = E_R° - E_L°$,

$$E_{cell}° = E°(Sn^{4+}/Sn^{2+}) - E°(Zn^{2+}/Zn) = +0.91\text{ V}$$



Rearrange Eq. 3 into $E_R° = E_{cell}° + E_L°$:

$$\begin{aligned} E°(Sn^{4+}/Sn^{2+}) &= E_{cell}° + E°(Zn^{2+}/Zn) \\ &= 0.91\text{ V} - 0.76\text{ V} \\ &= +0.15\text{ V} \end{aligned}$$

Evaluate As expected, the Sn^{4+}/Sn^{2+} electrode has the more positive standard potential.

Self-Test 13.6A The standard potential of the Ag^+/Ag couple is +0.80 V, and the standard potential of the cell $Pt(s)|I_2(s)|I^-(aq)||Ag^+(aq)|Ag(s)$ is +0.26 V at the same temperature. What is the standard potential of the I_2/I^- couple?

[***Answer:*** +0.54 V]

Self-Test 13.6B The standard potential of the Fe^{2+}/Fe couple is −0.44 V and the standard potential of the cell $Fe(s)|Fe^{2+}(aq)||Pb^{2+}(aq)|Pb(s)$ is +0.31 V. What is the standard potential of the Pb^{2+}/Pb couple?

In some cases, we find that available tables of data do not contain the standard potential that we need but do contain closely related values for the same element. For instance, we might require the standard potential of the Ce^{4+}/Ce couple, whereas we know only the values for the Ce^{3+}/Ce and Ce^{4+}/Ce^{3+} couples. In such cases, the potential of a couple cannot in general be determined by adding or subtracting the standard potentials directly. Instead, we calculate the values of $\Delta G°$ for each half-reaction and combine them into the $\Delta G°$ for the desired half-reaction. We then convert that value of $\Delta G°$ into the corresponding standard potential by using Eq. 2.

EXAMPLE 13.6 Calculating the standard potential of a couple from two related couples

Use the information in Appendix 2B to determine the standard potential for the redox couple Ce^{4+}/Ce, for which the reduction half-reaction is

$$Ce^{4+}(aq) + 4\,e^- \longrightarrow Ce(s) \qquad \textbf{(B)}$$

PLAN Use the alphabetical listing in Appendix 2B to find half-reactions that can be combined to give the desired half-reaction. Combine these half-reactions and their Gibbs free energies of reaction. Convert the Gibbs free energies into standard potentials by using Eq. 2 and then simplify the resulting expressions.

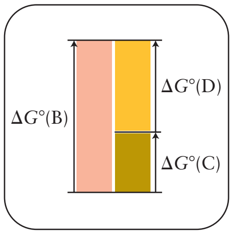
SOLVE From the data in Appendix 2B,

$$Ce^{3+}(aq) + 3\,e^- \longrightarrow Ce(s) \qquad E° = -2.48\text{ V} \qquad \textbf{(C)}$$

$$Ce^{4+}(aq) + e^- \longrightarrow Ce^{3+}(aq) \qquad E° = +1.61\text{ V} \qquad \textbf{(D)}$$

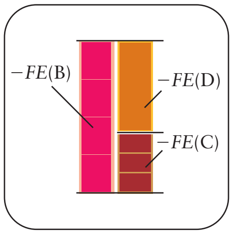
Add the reaction Gibbs free energies to get the overall reaction Gibbs free energy.

$$\Delta G°(\mathrm{B}) = \Delta G°(\mathrm{C}) + \Delta G°(\mathrm{D})$$



From $\Delta G_r° = -nFE°$,

$$-4FE°(\mathrm{B}) = -3FE°(\mathrm{C}) + \{-FE°(\mathrm{D})\}$$



Divide by $-4F$.

$$E°(\mathrm{B}) = \frac{3E°(\mathrm{C}) + E°(\mathrm{D})}{4}$$

Insert the data.

$$E°(\mathrm{B}) = \frac{3(-2.48\ \mathrm{V}) + 1.61\ \mathrm{V}}{4} = -1.46\ \mathrm{V}$$

Note that this value is not the same as the sum of the potentials for half-reactions C and D (−0.87).

Self-Test 13.7A Use the data in Appendix 2B to calculate the standard potential of the couple $Au^{3+}(aq)/Au^{+}(aq)$.

[***Answer:*** +1.26 V]

Self-Test 13.7B Use the data in Appendix 2B to calculate the standard potential of the couple $Mn^{3+}(aq)/Mn(s)$.

The standard potential of an electrode is the standard potential of a cell in which the electrode on the left in the cell diagram is a hydrogen electrode. A metal with a negative standard potential has a thermodynamic tendency to reduce hydrogen ions in solution; the ions of a metal with a positive standard potential have a tendency to be reduced by hydrogen gas.

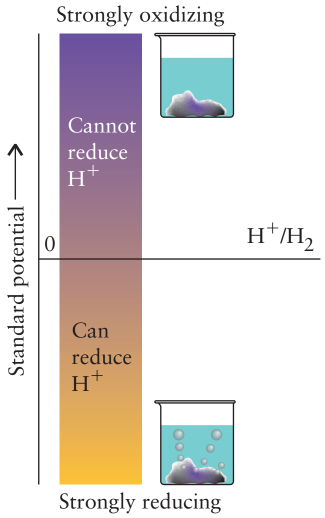


FIGURE 13.10 The significance of standard potentials. Only couples with negative standard potentials (and hence lying below hydrogen in the electrochemical series) can reduce hydrogen ions under standard conditions. The reducing power increases as the standard potential decreases.

13.7 The Electrochemical Series

When redox couples are ordered by their standard potentials, we have a list of oxidizing and reducing agents ordered by their strengths. As we have seen, *the more negative the standard potential of a couple, the greater its reducing strength*. Only a couple with a negative potential can reduce hydrogen ions under standard conditions (that is, have $K > 1$ for the reduction of hydrogen ions). A couple with a positive potential, such as Au^{3+}/Au, cannot reduce hydrogen ions under standard conditions in the sense that such a reaction would have $K < 1$, and commonly $K \ll 1$ for the reduction of hydrogen ions (Fig. 13.10).

When Table 13.1 is viewed as a table of relative strengths of oxidizing and reducing agents, it is called the **electrochemical series.** The species on the left of each equation in Table 13.1 are potentially oxidizing agents. They can themselves be reduced. Species on the right of the equations are potentially reducing agents. An oxidized species in the list (on the left of the equation) has a tendency (in the sense that $K > 1$) to oxidize a reduced species that lies below it. For example, Cu^{2+} ions oxidize zinc metal. A reduced species (on the right of the equation) has a tendency to reduce an oxidized species that lies above it. For example, zinc metal reduces H^{+} ions to hydrogen gas.

The higher the position of a species on the left side of an equation in Table 13.1, the greater its oxidizing strength. For example, F_2 is a strong oxidizing agent, whereas Li^+ is a very, very poor oxidizing agent. It also follows that, the lower the standard potential, the greater the reducing strength of the reduced species on the right side of an equation in Table 13.1. For example, lithium metal is the strongest reducing agent in the table.

Self-Test 13.8A Can lead produce zinc metal from aqueous zinc sulfate under standard conditions?

[***Answer:*** No, because lead lies above zinc in Table 13.1.]

Self-Test 13.8B Can chlorine gas oxidize water to oxygen gas under standard conditions in basic solution?

We can use the electrochemical series to predict whether a reaction has $K > 1$ or $K < 1$. A cell reaction that has $K > 1$ has $E_{cell}° > 0$. The standard cell potential is positive when the standard potential for the reduction half-reaction is more positive than that for the oxidation half-reaction.

EXAMPLE 13.7 Calculating the standard cell potential for a redox reaction

Acidified aqueous permanganate solutions and acidified aqueous dichromate solutions are powerful oxidizing agents. Suppose solutions of the two reagents are prepared and serve as the two half-cells in a galvanic cell with platinum electrodes that generates a current in an external circuit. (a) Determine the standard potential of the cell constructed from these half-cells. (b) Write the net ionic equation for the cell having a positive standard potential. (c) Write the cell diagram for the reaction.

Anticipate The permanganate standard potential lies above that of the dichromate ion in Table 13.1. Therefore, we should expect that under standard conditions the permanganate ion will act as the oxidizing agent in the reaction and the dichromate ion the reducing agent.

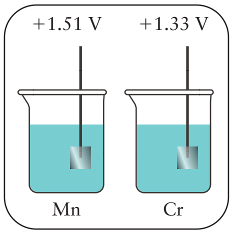
PLAN Find the standard potentials of the two reduction half-reactions in Appendix 2B. The couple with the higher standard potential will act as an oxidizing agent (and be the site of reduction). That couple will be the right-hand electrode in the cell diagram corresponding to a spontaneous reaction under standard conditions. To calculate the standard potential of the cell, subtract the standard potential of the oxidation half-reaction (the one with the lower standard potential) from that of the reduction half-reaction. To write the cell reaction, follow the procedure in Toolbox 13.2.

SOLVE

(a) Find the two standard potentials in Appendix 2B.

$$MnO_4^-(aq) + 8\,H^+(aq) + 5\,e^- \longrightarrow Mn^{2+}(aq) + 4\,H_2O(l) \qquad E° = +1.51\text{ V}$$

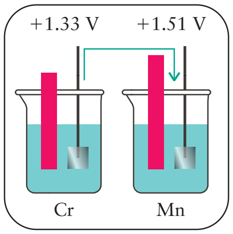
$$Cr_2O_7^{2-}(aq) + 14\,H^+(aq) + 6\,e^- \longrightarrow 2\,Cr^{3+}(aq) + 7\,H_2O(l) \qquad E° = +1.33\text{ V}$$



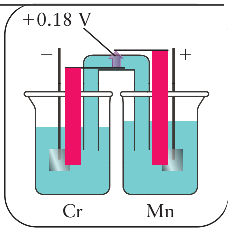
The half-reaction with the higher value of $E°$ occurs at the cathode in a cell reaction with a positive potential.

$$E°(MnO_4^-,H^+/Mn^{2+},H_2O) > E°(Cr_2O_7^{2-},H^+/Cr^{3+},H_2O)$$

Therefore, MnO_4^- serves as the cathode under standard conditions.



Find the standard potential from $E° = E°$(for reduction) − $E°$(for oxidation).



$$E° = 1.51\text{ V} - 1.33\text{ V}$$
$$= +0.18\text{ V}$$

(b) To construct the cell reaction, combine the two half-reactions, leaving the permanganate half-reaction as a reduction and reversing the dichromate half-reaction. To match numbers of electrons, multiply the manganese half-reaction by 6 and the chromium half-reaction by 5:

$$10\,Cr^{3+}(aq) + 35\,H_2O(l) \longrightarrow 5\,Cr_2O_7^{2-}(aq) + 70\,H^+(aq) + 30\,e^-$$
$$6\,MnO_4^-(aq) + 48\,H^+(aq) + 30\,e^- \longrightarrow 6\,Mn^{2+}(aq) + 24\,H_2O(l)$$

Their net sum gives the cell reaction:

$$6\,MnO_4^-(aq) + 11\,H_2O(l) + 10\,Cr^{3+}(aq) \longrightarrow 6\,Mn^{2+}(aq) + 22\,H^+(aq) + 5\,Cr_2O_7^{2-}(aq)$$

(c) Write the cell diagram with the cathode on the right-hand side:

$$Pt(s)|Cr_2O_7^{2-}(aq),Cr^{3+}(aq),H^+(aq)||H^+(aq),MnO_4^-(aq),Mn^{2+}(aq)|Pt(s)$$

Evaluate As expected, the permanganate ion is the oxidizing agent in the cell reaction and the dichromate ion the reducing agent.

Self-Test 13.9A Which metal, zinc or nickel, is the stronger reducing agent in aqueous solution under standard conditions? (a) Evaluate the standard potential of the appropriate cell; (b) specify the cell with a cell diagram; (c) write the net ionic equation for the spontaneous reaction; (d) state your answer to the question.

[***Answer:*** (a) +0.53 V; (b) $Zn(s)|Zn^{2+}(aq)||Ni^{2+}(aq)|Ni(s)$; (c) $Zn(s) + Ni^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Ni(s)$; (d) zinc]

Self-Test 13.9B Which is the stronger oxidizing agent, Cu^{2+} or Ag^+, in aqueous solution under standard conditions? Evaluate the standard potential of the appropriate cell, specify the cell with a cell diagram, and write the net ionic equation for the corresponding cell reaction.

The oxidizing and reducing power of a redox couple determines its position in the electrochemical series. The strongest oxidizing agents are at the top left of the table; the strongest reducing agents are at the bottom right of the table.

13.8 Standard Potentials and Equilibrium Constants

One of the most useful applications of standard potentials is in the calculation of equilibrium constants from electrochemical data. Perhaps surprisingly, the reactions need not be redox reactions: the techniques that we develop here can be applied to any kind of reaction, including neutralization and precipitation reactions, provided that they can be expressed as the difference of two reduction half-reactions. For example, even a "reaction" as simple as the expansion of a gas can be expressed as the difference of two reduction half-reactions:

$$\text{R:}\quad 2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g, P_2)$$
$$\text{L:}\quad 2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g, P_1)$$
$$\text{R} - \text{L:}\quad H_2(g, P_1) \longrightarrow H_2(g, P_2)$$

We saw in Section 10.3 that the standard reaction Gibbs free energy, $\Delta G_r°$ (remember that the r signifies the molar convention) is related to the equilibrium constant of the

reaction by $\Delta G_r° = -RT \ln K$. In this chapter, we have seen that the standard reaction Gibbs free energy is related to the standard potential of a galvanic cell by $\Delta G_r° = -nFE_{cell}°$, with n a pure number. When we combine the two equations, we get

$$nFE_{cell}° = RT \ln K \qquad (4)$$

This expression can be rearranged to allow us to calculate the equilibrium constant from the standard cell potential:

$$\ln K = \frac{nFE°}{RT} \qquad (5)^*$$

A note on good practice: Equation 5 was derived on the basis of the "molar" convention for writing the reaction Gibbs free energy; that means that the n must be interpreted as a pure number. That convention keeps the units straight: $FE_{cell}°$ has the units joules per mole, so does RT, so the ratio $FE_{cell}°/RT$ is a pure number and, with n a pure number, the right hand side is a pure number too (as it must be, if it is to be equal to a logarithm).

Because the magnitude of K increases exponentially with $E_{cell}°$, a reaction with a large positive $E_{cell}°$ has $K \gg 1$. A reaction with a large negative $E_{cell}°$ has $K \ll 1$.

Thinking point: What is the value of K for a reaction that has $E_{cell}° = 0$?

The fact that we can calculate $E_{cell}°$ from standard potentials allows us to calculate equilibrium constants for any reaction that can be expressed as two half-reactions. The reaction does not need to be spontaneous nor does it have to be a redox reaction. Toolbox 13.3 summarizes the steps and Example 13.8 shows the steps in action.

TOOLBOX 13.3 HOW TO CALCULATE EQUILIBRIUM CONSTANTS FROM ELECTROCHEMICAL DATA

CONCEPTUAL BASIS

The logarithm of the equilibrium constant of a reaction is proportional to the standard potential of the corresponding cell. We can expect a cell reaction with a large positive potential to have a strong tendency to take place, and therefore to produce a high proportion of products at equilibrium. Therefore, we expect $K > 1$ when $E° > 0$ (and often $K \gg 1$). The opposite is true for a cell reaction with a negative standard potential.

PROCEDURE

The procedure for calculating an equilibrium constant from electrochemical data is as follows.

Step 1 Write the balanced equation for the reaction. Then find two reduction half-reactions in Appendix 2B that combine to give that equation. Reverse one of the half-reactions and add them together.

Step 2 Identify the numerical (unitless) value of n from the change in oxidation numbers or by examining the half-reactions (after multiplication by appropriate factors) for the number of electrons transferred in the balanced equation.

Step 3 To obtain $E_{cell}°$, subtract the standard potential of the half-reaction that was reversed (oxidation) from the standard potential of the half-reaction that was left as a reduction: $E° = E°(\text{for reduction}) - E°(\text{for oxidation})$. Alternatively, write a cell diagram for the reaction; in that case, $E_{cell}° = E_R° - E_L°$.

Step 4 Use the relation $\ln K = nFE_{cell}°/RT$ to calculate the value of K (with n a pure number).

At 25.00°C (298.15 K), RT/F = 0.025 693 V; so, at that temperature,

$$\ln K = \frac{nE_{cell}°}{0.025\,693\ \text{V}}$$

This procedure is illustrated in Example 13.8.

EXAMPLE 13.8 Calculating the equilibrium constant for a reaction

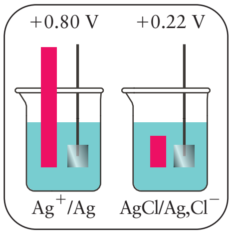
Calculate the equilibrium constant at 25.00°C for the reaction $AgCl(s) \longrightarrow Ag^+(aq) + Cl^-(aq)$. The equilibrium constant for this reaction is actually the solubility product, $K_{sp} = [Ag^+][Cl^-]$, for silver chloride (Section 12.8).

Anticipate Because silver chloride is almost insoluble, we expect K_{sp} to be very small (and $E_{cell}°$ therefore to be negative).

PLAN Follow the procedure in Toolbox 13.3.

SOLVE

Step 1 Find the two reduction half-reactions required for the cell reaction.



R: $AgCl(s) + e^- \longrightarrow Ag(s) + Cl^-(aq)$ $E° = +0.22$ V

L: $Ag^+(aq) + e^- \longrightarrow Ag(s)$ $E° = +0.80$ V

Reverse the second half-reaction.

$Ag(s) \longrightarrow Ag^+(aq) + e^-$

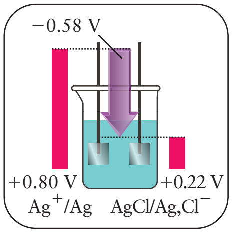
Add this equation to the reduction half-reaction and cancel species that appear on both sides of the equation.

$AgCl(s) \longrightarrow Ag^+(aq) + Cl^-(aq)$

Step 2 From the half-reactions note the stoichiometric coefficient for the number of electrons transferred.

$n = 1$

Step 3 Find $E_{cell}°$ from $E_{cell}° = E°(\text{for reduction}) - E°(\text{for oxidation})$.



$$E_{cell}° = 0.22\text{ V} - 0.80\text{ V} = -0.58\text{ V}$$

From $\ln K = nFE_{cell}°/RT = nE_{cell}°/(RT/F)$ with K identified with K_{sp} and $RT/F =$ 0.025 693 V at 298 K:

$$\ln K_{sp} = \frac{(1) \times (-0.58\text{ V})}{0.025\,693\text{ V}} = -\frac{0.58}{0.025\,693}$$

Take the antilogarithm (e^x) of $\ln K_{sp}$.

$$K_{sp} = e^{-0.58/0.025\,693} = 1.6 \times 10^{-10}$$

Evaluate The value of K_{sp} is indeed very small; it is also the same as that listed in Table 12.4. Many of the solubility products listed in tables were determined from potential measurements and calculations like this one.

Self-Test 13.10A Use Appendix 2B to calculate the solubility product of mercury(I) chloride, Hg_2Cl_2.

[***Answer:*** 2.6×10^{-18}]

Self-Test 13.10B Use the tables in Appendix 2B to calculate the solubility product of cadmium hydroxide, $Cd(OH)_2$.

The equilibrium constant of a reaction can be calculated from standard potentials by combining the equations for the half-reactions to give the cell reaction of interest and determining the standard potential of the corresponding cell.

13.9 The Nernst Equation

As a reaction proceeds toward equilibrium, the concentrations of its reactants and products change and ΔG approaches zero. Therefore, as reactants are consumed in a working electrochemical cell, the cell potential also decreases until finally it reaches

zero. A "dead" battery is one in which the cell reaction has reached equilibrium. At equilibrium, a cell generates zero potential difference across its electrodes and the reaction can no longer do work. To describe this behavior quantitatively, we need to find how the cell potential varies with the concentrations of species in the cell.

HOW DO WE DO THAT?

To establish how the cell potential depends on concentration, we first note that the potential is proportional to the reaction Gibbs free energy (Eq. 2). We already know how ΔG_r varies with composition:

$$\Delta G_r = \Delta G_r^\circ + RT \ln Q$$

where Q is the reaction quotient for the cell reaction (Eq. 5 of Section 10.3). Because $\Delta G_r = -nFE_{cell}$ and $\Delta G_r^\circ = -nFE_{cell}^\circ$, it follows at once that

$$-nFE_{cell} = -nFE_{cell}^\circ + RT \ln Q$$

At this point, we divide through by $-nF$ to get an expression for E_{cell} in terms of Q, which is given below.

The equation for the concentration dependence of the cell potential that we have derived,

$$E_{cell} = E_{cell}^\circ - \frac{RT}{nF} \ln Q \qquad \textbf{(6a)*}$$

(with n a pure number) is called the **Nernst equation** for the German electrochemist Walther Nernst, who first derived it. At 298.15 K, $RT/F = 0.025\,693$ V; so at that temperature the Nernst equation takes the form

$$E_{cell} = E_{cell}^\circ - \frac{0.025\,693 \text{ V}}{n} \ln Q \qquad \textbf{(6b)*}$$

It is sometimes convenient to use this equation with common logarithms, in which case we make use of the relation $\ln x = \ln 10 \times \log x = 2.303 \log x$. At 298.15 K,

$$E_{cell} = E_{cell}^\circ - \frac{RT \ln 10}{nF} \log Q = E_{cell}^\circ - \frac{0.059\,17 \text{ V}}{n} \log Q \qquad \textbf{(6c)*}$$

The Nernst equation is widely used to estimate the potentials of cells under nonstandard conditions. In biology it is used, among other things, to estimate the potential difference across biological cell membranes, such as those of neurons.

EXAMPLE 13.9 Using the Nernst equation to predict a cell potential

Calculate the potential of a Daniell cell at 25°C in which the concentration of Zn^{2+} ions is 0.10 mol·L^{-1} and that of the Cu^{2+} ions is 0.0010 mol·L^{-1}.

PLAN Write the balanced equation for the cell reaction and the corresponding expression for Q, and note the value of n. Then determine E_{cell}° from the standard potentials in Table 13.1 or Appendix 2B. Determine the value of Q for the stated conditions. Calculate the cell potential by substituting these values into the Nernst equation, Eq. 6b.

SOLVE The Daniell cell and the corresponding cell reaction are

$$Zn(s)|Zn^{2+}(aq)||Cu^{2+}(aq)|Cu(s) \qquad Cu^{2+}(aq) + Zn(s) \longrightarrow Zn^{2+}(aq) + Cu(s)$$

Set up the reaction quotient.

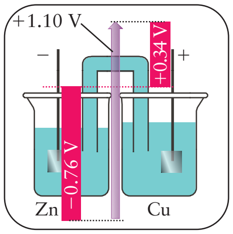
$$Q = \frac{a_{Zn^{2+}}}{a_{Cu^{2+}}} = \frac{[Zn^{2+}]}{[Cu^{2+}]} = \frac{0.10}{0.0010}$$

From the balanced equation, note the value of n.

$$n = 2$$

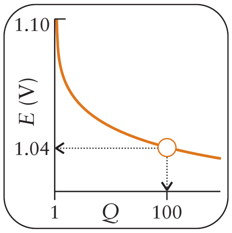
Determine the value of $E_{cell}° = E_R° - E_L°$.

$$E_{cell}° = 0.34 - (-0.76)\ \text{V} = +1.10\ \text{V}$$



From $E_{cell} = E_{cell}° - (RT/nF) \ln Q$,

$$E_{cell} = 1.10\ \text{V} - \frac{0.025\ 693\ \text{V}}{2} \ln \frac{0.10}{0.0010}$$
$$= 1.10\ \text{V} - 0.059\ \text{V}$$
$$= +1.04\ \text{V}$$



Self-Test 13.11A Calculate the potential of the cell $Zn(s)|Zn^{2+}(aq, 1.50\ mol{\cdot}L^{-1})\|Fe^{2+}(aq, 0.10\ mol{\cdot}L^{-1})|Fe(s)$.

[***Answer:*** +0.29 V]

Self-Test 13.11B Calculate the potential of the cell $Ag(s)|Ag^{+}(aq, 0.0010\ mol{\cdot}L^{-1})\|Ag^{+}(aq, 0.010\ mol{\cdot}L^{-1})|Ag(s)$.

An important application of the Nernst equation is the measurement of concentration. In a **concentration cell,** the two electrodes are identical except for their concentrations. For such a cell, there is no driving force for change when the two concentrations are the same (which is the case when they are in their standard states), and so $E_{cell}° = 0$. Therefore, at 25°C the potential corresponding to the cell reaction is related to Q by $E_{cell} = -(0.025\ 693\ \text{V}/n) \ln Q$. For example, a concentration cell having two Ag^{+}/Ag electrodes is

$$Ag(s)|Ag^{+}(aq, L)\|Ag^{+}(aq, R)|Ag(s) \qquad Ag^{+}(aq, R) \longrightarrow Ag^{+}(aq, L)$$

The cell reaction has $n = 1$ and $Q = [Ag^{+}]_L/[Ag^{+}]_R$. If the concentration of Ag^{+} in the right-hand electrode is 1 $mol{\cdot}L^{-1}$, Q is equal to $[Ag^{+}]_L$, and the Nernst equation is

$$E_{cell} = -(0.025\ 693\ \text{V}) \ln [Ag^{+}]_L$$

Therefore, by measuring E_{cell}, we can infer the concentration of Ag^{+} in the left-hand electrode compartment. If the concentration of Ag^{+} ions in the left-hand electrode is less than that in the right, then $E_{cell} > 0$ for the cell as specified and the right-hand electrode will be found to be the cathode.

EXAMPLE 13.10 Using the Nernst equation to find a concentration

Each electrode compartment of a galvanic cell contains a silver electrode and 10.0 mL of 0.10 M $AgNO_3(aq)$; they are connected by a salt bridge. You now add 10.0 mL of 0.10 M NaCl(aq) to the left-hand electrode compartment. Almost all the silver precipitates as silver chloride but a little remains in solution as a saturated solution of AgCl. The measured cell potential is $E_{cell} = +0.42$ V. What is the concentration of Ag^{+} in the saturated solution?

Anticipate Because silver chloride is very insoluble, we should expect a very low concentration.

PLAN The cell is a concentration cell in which the concentration of Ag^{+} in one compartment is determined by the solubility of AgCl. Use the Nernst equation, Eq. 6, to find the concentration of Ag^{+} in the compartment with the precipitate. The standard cell potential is 0 (in their standard states the electrodes are identical). At 25.00°C, $RT/F = 0.025\ 693$ V.

SOLVE The cell and the corresponding cell reaction are

$$Ag(s)|Ag^{+}(aq, L)\|Ag^{+}(aq, R)|Ag(s) \qquad Ag^{+}(aq, R) \longrightarrow Ag^{+}(aq, L)$$

Set up the reaction quotient, Q.

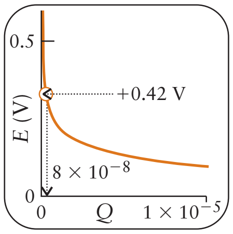
$$Q = \frac{[Ag^+]_L}{[Ag^+]_R} = \frac{[Ag^+]_L}{0.10}$$

From the balanced equation, note the value of n.

$n = 1$

From $E_{cell} = E_{cell}° - (RT/nF) \ln Q$ rearranged into $\ln Q = -E_{cell}/(RT/nF)$,

$$\ln Q = \frac{-0.42\ \text{V}}{0.025\,693\ \text{V}} = -16.34$$



From $Q = e^{\ln Q}$,

$Q = e^{-16.34}$

From $[Ag^+]_L = Q[Ag^+]_R$,

$[Ag^+]_L = e^{-16.34} \times 0.10 = 8.0 \times 10^{-9}$

Evaluate The concentration of Ag^+ ions in the saturated solution is 8.0 nmol·L^{-1}; as expected, this is a very low value.

Self-Test 13.12A Calculate the molar concentration of Y^{3+} in a saturated solution of YF_3 by using a cell constructed with two yttrium electrodes. The electrolyte in one compartment is 1.0 M $Y(NO_3)_3$(aq). In the other compartment you have prepared a saturated solution of YF_3. The measured cell potential is +0.34 V at 298 K.

[***Answer:*** 5.7×10^{-18} mol·L^{-1}]

Self-Test 13.12B Calculate the potential of a cell constructed with two silver electrodes. The electrolyte in one compartment is 1.0 M $AgNO_3$(aq). In the other compartment NaOH has been added to a $AgNO_3$ solution until the pH = 12.5 at 298 K.

The dependence of cell potential on composition is expressed by the Nernst equation, Eq. 6.

13.10 Ion-Selective Electrodes

An important application of the Nernst equation is the measurement of pH (and, through pH, acidity constants). The pH of a solution can be measured electrochemically with a device called a pH meter. The technique makes use of a cell in which one electrode is sensitive to the H_3O^+ concentration and another electrode serves as a reference. An electrode sensitive to the concentration of a particular ion is called an **ion-selective electrode.**

One combination of electrodes that could be used to determine pH is a hydrogen electrode connected through a salt bridge to a *calomel electrode*. The reduction half-reaction for the calomel electrode is

Calomel is the common name for mercury(I) chloride, Hg_2Cl_2. Note that the compound contains the diatomic cation Hg_2^{2+}.

$$Hg_2Cl_2(s) + 2\,e^- \longrightarrow 2\,Hg(l) + 2\,Cl^-(aq) \qquad E° = +0.27\ \text{V}$$

The overall cell reaction is

$$Hg_2Cl_2(s) + H_2(g) \longrightarrow 2\,H^+(aq) + 2\,Hg(l) + 2\,Cl^-(aq) \qquad Q = \frac{[H^+]^2[Cl^-]^2}{P_{H_2}}$$

Provided that the pressure of hydrogen is 1 bar, we can write the reaction quotient as $Q = [H^+]^2[Cl^-]^2$. To find the concentration of hydrogen ions, we write the Nernst equation:

$$E_{cell} = E_{cell}° - \frac{RT}{2F} \ln ([H^+]^2[Cl^-]^2)$$

FIGURE 13.11 A glass electrode in a protective plastic sleeve (left) is used to measure pH. It is used in conjunction with a thermometer (right) in pH meters such as this one.

We apply $\ln(ab) = \ln a + \ln b$,

$$E_{cell} = E_{cell}{}^{\circ} - \frac{RT}{2F}\ln([Cl^-]^2) - \frac{RT}{2F}\ln([H^+]^2)$$

then use $\ln a^2 = 2\ln a$ to obtain

$$E_{cell} = E_{cell}{}^{\circ} - (RT/F)\ln[Cl^-] - (RT/F)\ln[H^+]$$

The Cl^- concentration of a calomel electrode is fixed at the time of manufacture by saturating the solution with KCl, and so $[Cl^-]$ is a constant. We can therefore combine the first two terms on the right into a single constant, $E_{cell}' = E_{cell}{}^{\circ} - (RT/F)\ln[Cl^-]$:

$$E_{cell} = E_{cell}' - (RT/F)\ln[H^+]$$

Then, because $\ln x = \ln 10 \times \log x$, and $(RT/F)\ln 10 = (0.026\,93\ \text{V}) \times 2.303 = 0.0592\ \text{V}$ at 25°C,

$$E_{cell} = E_{cell}' - (RT/F)\ln 10 \times \log[H^+]$$
$$= E_{cell}' + (0.0592\ \text{V}) \times \text{pH}$$

Therefore, by measuring the cell potential, E_{cell}, we can determine the pH. The value of E_{cell}' is established by calibrating the cell, which requires measuring E for a solution of known pH.

A **glass electrode**, a thin-walled glass bulb containing an electrolyte, is much easier to use than a hydrogen electrode and has a potential that varies linearly with the pH of the solution outside the glass bulb (Fig. 13.11). Often there is a calomel electrode built into the probe that makes contact with the test solution through a miniature salt bridge. A pH meter therefore usually has only one probe, which forms a complete electrochemical cell once it is dipped into a solution. The meter is calibrated with a buffer of known pH, and the measured cell potential is then automatically converted into the pH of the solution, which is displayed.

Commercially available electrodes used in *pX meters* are sensitive to other ions, such as Na^+, Ca^{2+}, $NH_4{}^+$, CN^-, or S^{2-}. They are used to monitor industrial processes and in pollution control.

The pH or concentrations of ions can be measured by using an electrode that responds selectively to only one species of ion.

ELECTROLYTIC CELLS

Redox reactions that have a positive Gibbs free energy of reaction are not spontaneous, but an electric current can be used to make them take place. For example, there is no common spontaneous chemical reaction in which fluorine is a product, and so the element cannot be isolated by any common chemical reaction. It was not until 1886 that the French chemist Henri Moissan found a way to force the formation of fluorine by passing an electric current through an anhydrous molten mixture of potassium fluoride and hydrogen fluoride. Fluorine is still prepared commercially by the same process.

In the next two sections we study **electrolysis,** the process of driving a reaction in a nonspontaneous direction by using an electric current. First, we see how electrochemical cells are constructed for electrolysis and how to predict the potential needed to bring electrolysis about. Then, we examine the products of electrolysis and see how to predict the amount of products to expect for a given flow of electric current.

13.11 Electrolysis

An electrochemical cell in which electrolysis takes place is called an **electrolytic cell.** The arrangement of components in electrolytic cells is different from that in galvanic cells. Typically, the two electrodes share the same compartment, there is only one electrolyte, and concentrations and pressures are far from standard. As in all electrochemical cells,

the current is carried through the electrolyte by the ions present. For example, when copper metal is refined electrolytically, the anode is impure copper, the cathode is pure copper, and the electrolyte is an aqueous solution of $CuSO_4$. As the Cu^{2+} ions in solution migrate toward the cathode, where they are reduced and deposited as Cu atoms, more Cu^{2+} ions are produced by oxidation of copper metal at the anode.

Figure 13.12 shows schematically the layout of an electrolytic cell used for the commercial production of magnesium metal from molten magnesium chloride (the *Dow process*). As in a galvanic cell, oxidation takes place at the anode and reduction takes place at the cathode, electrons travel through the external wire from anode to cathode, cations move through the electrolyte toward the cathode, and anions move toward the anode. But unlike in a galvanic cell, in which the current is spontaneously generated, in an electrolytic cell a current must be supplied by an external electrical power source for reaction to occur. That power source can be a galvanic cell, which provides the current that drives electrons through the wire in a predetermined direction. The result is to force oxidation at one electrode and reduction at the other. For example, the following half-reactions are made to take place in the Dow process:

The anode (the site of oxidation) of an electrolytic cell is labeled + and the cathode (the site of reduction) is labeled −, the opposite of a galvanic cell. The + sign indicates that the electrode is pulling electrons away from the electroactive species undergoing oxidation.

Anode reaction: $2\ Cl^-(melt) \longrightarrow Cl_2(g) + 2\ e^-$

Cathode reaction: $Mg^{2+}(melt) + 2\ e^- \longrightarrow Mg(l)$

where "melt" signifies the molten salt. A rechargeable battery functions as a galvanic cell when it is doing work and as an electrolytic cell when it is being recharged.

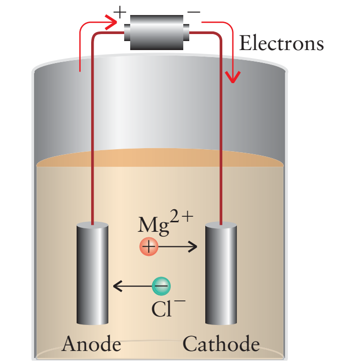


FIGURE 13.12 A schematic representation of the electrolytic cell used in the Dow process for magnesium. The electrolyte is molten magnesium chloride. As the current generated by the external source passes through the cell, chloride ions are oxidized to chlorine gas at the anode and magnesium ions are reduced to magnesium metal at the cathode.

To drive a reaction in a nonspontaneous direction, the external supply must generate a potential difference greater than the potential difference that would be produced by the reverse reaction. For example, because

$$2\ H_2(g) + O_2(g) \longrightarrow 2\ H_2O(l) \qquad E_{cell} = +1.23\ V \text{ at pH} = 7\text{, spontaneous}$$

to achieve the nonspontaneous reverse reaction

$$2\ H_2O(l) \longrightarrow 2\ H_2(g) + O_2(g) \qquad E_{cell} = -1.23\ V \text{ at pH} = 7\text{, nonspontaneous}$$

under standard conditions (other than for the H^+ concentration) we must apply at least 1.23 V from the external source to overcome the reaction's natural pushing power in the opposite direction. In practice, the applied potential difference must usually be substantially greater than the cell potential to reverse a spontaneous cell reaction and achieve a significant rate of product formation. The additional potential difference, which varies with the type of electrode, is called the **overpotential**. For platinum electrodes, the overpotential for the production of water from hydrogen and oxygen is about 0.6 V; so about 1.8 V (that is, 0.6 + 1.23 V) is actually required to electrolyze water when platinum electrodes are used. Much contemporary research on electrochemical cells involves attempts to reduce the overpotential and hence to increase the efficiency of electrolytic processes.

When carrying out an electrolysis in solution, we must consider the possibility that other species present might be oxidized or reduced by the electric current. For example, suppose that we want to electrolyze water to produce hydrogen and oxygen. Pure water does not carry a current because the concentration of ions (H_3O^+ and OH^-) in it is very low. Therefore, we must add an ionic solute with ions that are less easily oxidized or reduced than water:

$$O_2(g) + 4\ H^+(aq) + 4\ e^- \longrightarrow 2\ H_2O(l) \qquad E = +0.82\ V \text{ at pH} = 7$$

To reverse this half-reaction and bring about the oxidation of water, we need an applied potential difference of at least 0.82 V. Suppose the added salt is sodium chloride. When Cl^- ions are present at 1 mol·L^{-1} in water, is it possible that they, and not the water, will be oxidized? From Table 13.1, the standard potential for the reduction of chlorine is +1.36 V:

$$Cl_2(g) + 2\ e^- \longrightarrow 2\ Cl^-(aq) \qquad E° = +1.36\ V$$

To reverse this reaction and oxidize chloride ions, we have to supply at least 1.36 V. Because only 0.82 V is needed to force the oxidation of water but 1.36 V is needed to

force the oxidation of Cl^-, it appears that oxygen should be the product at the anode. However, the overpotential for oxygen production can be very high, and in practice chlorine also might be produced. At the cathode, we want the half-reaction $2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g)$ to take place. At pH = 7, the potential required for the reduction of hydrogen ions is 0.41 V. Hydrogen, rather than sodium metal, will be produced at the cathode, because the potential required to reduce sodium ions is significantly higher (+2.71 V). The most common salt used for the electrolysis of water is sodium sulfate, because neither ion reacts during electrolysis and the salt is inexpensive.

EXAMPLE 13.11 Deciding which species will be produced at an electrode

Suppose that an aqueous solution with pH = 7 and containing I^- ions at 1 $mol{\cdot}L^{-1}$ is being electrolyzed. Will O_2 or I_2 be produced at the anode?

PLAN Decide which oxidation requires the lower potential. Then, provided the overpotentials are similar, that couple will be preferentially oxidized.

SOLVE From Table 13.1,

$$I_2(s) + 2\,e^- \longrightarrow 2\,I^-(aq) \qquad E° = +0.54\text{ V}$$

so we know that at least 0.54 V is needed to oxidize I^-. We have seen that at least 0.82 V is needed to oxidize water:

$$O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l) \qquad E = +0.82\text{ V at pH} = 7$$

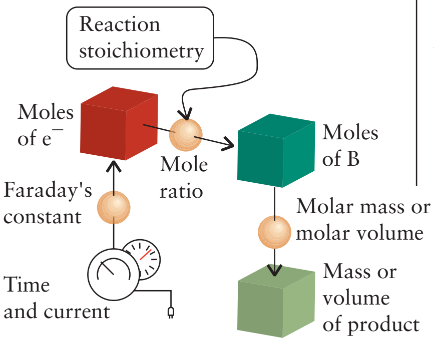
Therefore, provided that the overpotentials are similar, we expect I^- ions to be oxidized in preference to water.

Self-Test 13.13A Predict the products resulting from the electrolysis of 1 M $AgNO_3(aq)$.

[***Answer:*** Cathode, Ag; anode, O_2]

Self-Test 13.13B Predict the products resulting from the electrolysis of 1 M NaBr(aq).

The potential supplied to an electrolytic cell must be at least as great as that of the cell reaction to be reversed. If there is more than one reducible species in solution, the species with the greater potential for reduction is preferentially reduced. The same principle applies to oxidation.



1

13.12 The Products of Electrolysis

We saw in Section L how to calculate the maximum amount of product that can be formed from a given amount of a reactant. Now we shall see how to calculate the amount of product formed by a given amount of electricity (**1**). The calculation is based on observations made by Michael Faraday (Fig.13.13) and summarized—in more modern language than he used—as follows:

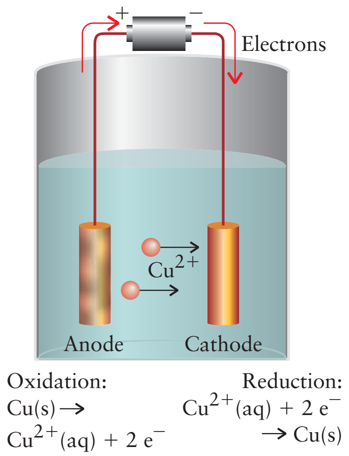
> **Faraday's law of electrolysis:** The amount of product formed or reactant consumed by an electric current is stoichiometrically equivalent to the amount of electrons supplied.

FIGURE 13.13 Michael Faraday (1791–1867).

To find the amount (in moles) of product that can be formed by an electrical current passed for a given time, we need to take into account the amount of product that can be formed by a given amount of electrons. For instance, copper is refined electrolytically by using an impure form of copper metal called blister copper as the anode in an electrolytic cell (Fig. 13.14). The current supply drives the oxidation of the blister copper to copper(II) ions, Cu^{2+}, which are then reduced to pure copper metal at the cathode in the reaction $Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s)$. To calculate the amount of Cu produced by using 4.0 mol e^- we write the mole ratio from this half-reaction, 2 mol $e^- \simeq$ 1 mol Cu, and then convert the amount of electrons to an amount of Cu atoms:

$$\begin{aligned}\text{Amount of Cu (mol)} &= (4.0\text{ mol e}^-) \times \frac{1\text{ mol Cu}}{2.0\text{ mol e}^-}\\ &= 2.0\text{ mol Cu}\end{aligned}$$

FIGURE 13.14 A schematic representation showing the electrolytic process for refining copper. The anode is impure copper. The Cu^{2+} ions produced by oxidation of the anode migrate to the cathode, where they are reduced to pure copper metal. A similar arrangement is used for electroplating objects.



Lab Video 13.14

Self-Test 13.14A What amount (in moles) of Al(s) can be produced from Al_2O_3 if 5.0 mol e^- is supplied?

[***Answer:*** 1.7 mol Al]

Self-Test 13.14B What amount (in moles) of Cr(s) can be produced from CrO_3 if 12.0 mol e^- is supplied?

The quantity, Q, of electricity passed through the electrolysis cell is measured in coulombs. It is determined by measuring the current, I, and the time, t, for which the current flows and is calculated from

$$\text{Charge supplied (C)} = \text{current (A)} \times \text{time (s)} \qquad \text{or} \qquad Q = It \tag{7}$$

For example, because 1 A·s = 1 C, if 2.00 A is passed for 125 s, the charge supplied to the cell is

$$Q = (2.00\text{ A}) \times (125\text{ s}) = 250.\text{ A·s} = 250.\text{ C}$$

To determine the amount of electrons supplied by a given charge, we use Faraday's constant, F, the magnitude of the charge per mole of electrons (Section 13.4). Because the charge supplied is $Q = nF$, where n is the amount of electrons (in moles), it follows that

$$n = \frac{Q}{F} = \frac{It}{F} \tag{8}*$$

In this context, Q is the charge supplied: don't confuse it with the reaction quotient Q!

So, by measuring the current and the time for which it flows, we can determine the amount of electrons supplied. By combining the amount of electrons supplied with the mole ratio from the stoichiometry of the electrode reaction, we can deduce the amount of product obtained (see **1**).

TOOLBOX 13.4 HOW TO PREDICT THE RESULT OF ELECTROLYSIS

CONCEPTUAL BASIS

The number of electrons required to reduce a species is related to the stoichiometric coefficients in the reduction half-reaction. The same is true of oxidation. Therefore, we can set up a stoichiometric relation between the reduced or oxidized species and the amount of electrons required to carry out the reaction. The amount of electrons required is calculated from the current and the length of time for which the current flows.

PROCEDURE

To determine the amount of product that can be produced:

Step 1 Identify the stoichiometric relation between electrons and the species of interest from the applicable half-reaction.

Step 2 Calculate the amount (in moles) of electrons supplied from Eq. 8, $n = It/F$. Use the stoichiometric relation from step 1 to convert n into the amount of substance. If required, use the molar mass to convert the amount of substance into mass (or molar volume to convert into volume).

This procedure is illustrated in Example 13.12.

To determine the time required for a given amount of product to be produced:

Step 1 Identify the stoichiometric relation between electrons and the species of interest from the applicable half-reaction.

Step 2 If required, use the molar mass to convert mass into amount (in moles). Use the stoichiometric relation from step 1 to convert amount of substance into amount of electrons passed, n (in moles).

Step 3 Substitute n, the current, and Faraday's constant into Eq. 8 rearranged to $t = Fn/I$ and solve for time.

This procedure is illustrated in Example 13.13.

EXAMPLE 13.12 Calculating the amount of product formed by electrolysis

Aluminum is produced by electrolysis of its oxide dissolved in molten cryolite (Na_3AlF_6). Find the mass of aluminum that can be produced in 1.00 day in an electrolytic cell operating continuously at 1.00×10^5 A. The cryolite does not react.

Anticipate In this industrial-scale process, with a high current acting for a long time, we should expect to generate many kilograms of aluminum.

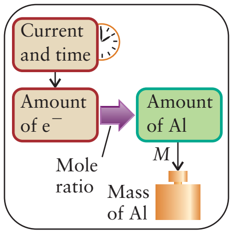
PLAN Use the first procedure in Toolbox 13.4.

SOLVE

Step 1 Write the half-reaction for the reduction and find the amount of electrons required to reduce 1 mol metal.

$$Al^{3+}(melt) + 3\ e^- \longrightarrow Al(l) \qquad 3\ mol\ e^- \mathrel{\hat{=}} 1\ mol\ Al$$

Step 2 From $m = nM$ and $n = It/F$, using $M(Al) = 26.98\ g\cdot mol^{-1}$, 3600 s = 1 h, and 24 h = 1 d, and remembering the stoichiometric relation between Al and the electrons:



$$m(Al) = n(e^-) \times \frac{1\ mol\ Al}{3\ mol\ e^-} \times \frac{26.98\ g\ Al}{1\ mol\ Al}$$

$$= \frac{(1.00 \times 10^5\ C\cdot s^{-1}) \times (24.0 \times 3600\ s)}{9.65 \times 10^4\ C\cdot(mol\ e^-)^{-1}} \times \frac{1\ mol\ Al}{3\ mol\ e^-} \times \frac{26.98\ g\ Al}{1\ mol\ Al}$$

$$= 8.05 \times 10^5\ g\ Al$$

Evaluate As expected, a large mass of aluminum (805 kg) is produced. The fact that the production of 1 mol Al requires 3 mol e^- accounts for the very high consumption of electricity characteristic of aluminum-production plants.

Self-Test 13.15A Determine the mass (in grams) of magnesium metal that can be obtained from molten magnesium chloride, by using a current of 7.30 A for 2.11 h. What volume of chlorine gas at 25°C and 1.00 atm will be produced at the anode?

[***Answer:*** 6.98 g; 7.03 L]

Self-Test 13.15B What mass of chromium metal can be obtained from a 1 M solution of CrO_3 in dilute sulfuric acid, by using a current of 6.20 A for 6.00 h?

EXAMPLE 13.13 **Calculating the time required to produce a given mass of product**

How many hours are required to plate 25.00 g of copper metal from 1.00 M $CuSO_4(aq)$, by using a current of 3.00 A?

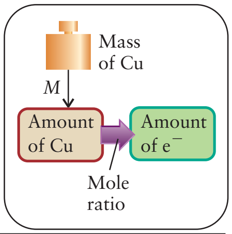
PLAN Use the second procedure in Toolbox 13.4.

SOLVE

Step 1 Find the stoichiometric relation between electrons and the species of interest from the half-reaction for the electrolysis.

$$Cu^{2+}(aq) + 2\ e^- \longrightarrow Cu(s) \qquad 2\ mol\ e^- \mathrel{\hat{=}} 1\ mol\ Cu$$

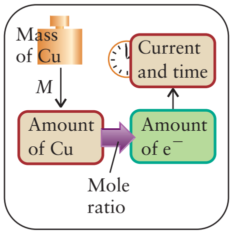
Step 2 To find $n(e^-)$, convert grams of Cu into moles of Cu and moles of Cu into moles of e^-.



$$n(e^-) = (25.00\ g\ Cu) \times \frac{1\ mol\ Cu}{63.54\ g\ Cu} \times \frac{2\ mol\ e^-}{1\ mol\ Cu}$$

$$= \frac{25.00 \times 2}{63.54} mol\ e^-$$

Step 3 Use $t = Fn/I$ and convert seconds to hours.



$$t = \frac{9.6485 \times 10^4 C\cdot(mol\ e^-)^{-1}}{3.00\ C\cdot s^{-1}} \times \frac{25.00 \times 2}{63.54} mol\ e^- \times \frac{1\ h}{3600\ s}$$

$$= 7.0\ h$$

Self-Test 13.16A Determine the time, in hours, required to electroplate 7.00 g of magnesium metal from molten magnesium chloride, by using a current of 7.30 A.

[*Answer:* 2.12 h]

Self-Test 13.16B How many hours are required to plate 12.00 g of chromium metal from a 1 M solution of CrO_3 in dilute sulfuric acid, by using a current of 6.20 A?

The amount of product in an electrolysis reaction is calculated from the stoichiometry of the half-reaction, the current, and the time for which the current flows.

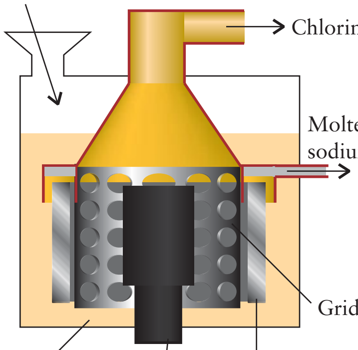


FIGURE 13.15 In the Downs process, molten sodium chloride is electrolyzed with a graphite anode (at which the Cl^- ions are oxidized to chlorine) and a steel cathode (at which the Na^+ ions are reduced to sodium). The sodium and chlorine are kept apart by the hoods surrounding the electrodes. Calcium chloride is present to lower the melting point of sodium chloride to an economical temperature.

THE IMPACT ON MATERIALS

Electrochemical cells play important roles in both the purification and the preservation of metallic materials. Redox reactions are used throughout the chemical industry to extract metals from their ores. However, redox reactions also corrode the artifacts that industry produces. What redox reactions achieve, redox reactions can destroy.

13.13 Applications of Electrolysis

We have already described the refining of copper and the electrolytic extraction of aluminum, magnesium, and fluorine. Another important industrial application of electrolysis is the production of sodium metal by the *Downs process*, the electrolysis of molten rock salt (Fig. 13.15):

Cathode reaction: $2\,Na^+(melt) + 2\,e^- \longrightarrow 2\,Na(l)$

Anode reaction: $2\,Cl^-(melt) \longrightarrow Cl_2(g) + 2\,e^-$

Sodium chloride is plentiful as the mineral rock salt, but the solid does not conduct electricity because the ions are locked into place. Sodium chloride must be molten for electrolysis to occur. The electrodes in the cell are made of inert materials such as carbon, and the cell is designed to keep the sodium and chlorine produced by the electrolysis out of contact with each other and away from air. In a modification of the Downs process, the electrolyte is an aqueous solution of sodium chloride (see Section 15.6). The products of this *chloralkali process* are chlorine and aqueous sodium hydroxide.

Thinking point: In the Downs process $CaCl_2$ is added to the NaCl to reduce the latter's melting point. Why then is calcium metal not produced at the cathode?

Electroplating is the electrolytic deposition of a thin film of metal on an object (Fig. 13.16). The object to be electroplated (either metal or graphite-coated plastic)

FIGURE 13.16 Chromium plating lends decorative flair as well as electrochemical protection to the steel of this motorcycle. Large quantities of electricity are needed for chromium plating because six electrons are required to produce each atom of chromium from chromium(VI) oxide.

FIGURE 13.17 Iron nails stored in oxygen-free water (left) do not rust, because the oxidizing power of water itself is weak. When oxygen is present (as a result of air dissolving in the water, right), oxidation is thermodynamically spontaneous and rust soon forms.

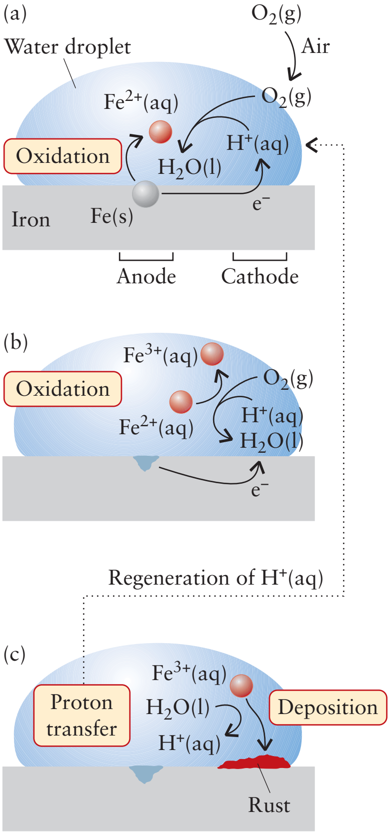

FIGURE 13.18 The mechanism of rust formation in a drop of water. (a) Oxidation of the iron occurs at a location out of contact with the oxygen of the air. The surface of the metal acts as an anode in a tiny galvanic cell, with the metal at the outer edge of the drop serving as the cathode. (b) Further oxidation of Fe^{2+} results in the formation of Fe^{3+} ions. (c) Protons are removed from H_2O as oxide ions combine with Fe^{3+} ions to deposit as rust. These protons are recycled, as indicated by the dotted line.

constitutes the cathode, and the electrolyte is an aqueous solution of a salt of the plating metal. Metal is deposited on the cathode by reduction of ions in the electrolyte solution. These cations are supplied either by the added salt or from oxidation of the anode, which is made of the plating metal.

Electrolysis is used industrially to produce aluminum and magnesium; to extract metals from their salts; to prepare chlorine, fluorine, and sodium hydroxide; to refine copper; and in electroplating.

13.14 Corrosion

Corrosion is the unwanted oxidation of a metal. It cuts short the lifetimes of steel products such as bridges and automobiles, and replacing corroded metal parts costs billions of dollars a year. Corrosion is an electrochemical process, and the electrochemical series is a source of insight into why corrosion occurs and how to prevent it.

The main culprit in corrosion is water. One half-reaction that we have to take into account is

$$2\,H_2O(l) + 2\,e^- \longrightarrow H_2(g) + 2\,OH^-(aq) \qquad E° = -0.83\text{ V}$$

This standard potential is for an OH^- concentration of 1 mol·L^{-1}, which corresponds to pH = 14, a strongly basic solution. However, from the Nernst equation, we can calculate that, at pH = 7, this couple has $E = -0.42$ V. Any metal with a standard potential more negative than −0.42 V can therefore reduce water at pH = 7: that is, at this pH, any such metal can be oxidized by water. Because $E° = -0.44$ V for $Fe^{2+}(aq) + 2\,e^- \longrightarrow Fe(s)$, iron has only a very slight tendency to be oxidized by water at pH = 7. For this reason, iron can be used for pipes in water supply systems and can be stored in oxygen-free water without rusting (Fig. 13.17).

The rusting of iron in the environment occurs when iron is exposed to damp air, with both oxygen and water present. Then the half-reaction

$$O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l) \qquad E° = +1.23\text{ V}$$

must be taken into account. The potential of this half-reaction at pH = 7 and $p(O_2) = 0.2$ bar is +0.81 V, which lies well above the value for iron. Hence, iron can reduce oxygen in aqueous solution at pH = 7. In other words, oxygen and water can jointly oxidize iron metal to iron(II) ions. They can also subsequently work together to oxidize the iron(II) ions to iron(III), because $E° = +0.77$ V for $Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq)$.

Let's look in more detail at the processes. A drop of water on the surface of iron can act as the electrolyte for corrosion in a tiny electrochemical cell (Fig. 13.18). At the edge of the drop, dissolved oxygen oxidizes the iron in the process

$$2\,Fe(s) \longrightarrow 2\,Fe^{2+}(aq) + 4\,e^-$$
$$O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l)$$
$$\text{Overall: } 2\,Fe(s) + O_2(g) + 4\,H^+(aq) \longrightarrow 2\,Fe^{2+}(aq) + 2\,H_2O(l) \qquad \textbf{(E)}$$

The electrons withdrawn from the metal by this oxidation can be restored from another part of the conducting metal—in particular, from iron lying beneath the oxygen-poor region in the center of the drop. The iron atoms there give up their electrons to the iron atoms at the edge of the drop, form Fe^{2+} ions, and drift away into the surrounding water. This process results in the formation of tiny pits in the surface of the iron. The Fe^{2+} ions are then oxidized further to Fe^{3+} by the dissolved oxygen:

$$2\,Fe^{2+}(aq) \longrightarrow 2\,Fe^{3+}(aq) + 2\,e^-$$
$$\tfrac{1}{2}\,O_2(g) + 2\,H^+(aq) + 2\,e^- \longrightarrow H_2O(l)$$
$$\text{Overall: } 2\,Fe^{2+}(aq) + \tfrac{1}{2}\,O_2(g) + 2\,H^+(aq) \longrightarrow 2\,Fe^{3+}(aq) + H_2O(l) \qquad \textbf{(F)}$$

These ions then precipitate as a hydrated iron(III) oxide, $Fe_2O_3 \cdot H_2O$, the brown, insoluble substance that in its impure form we call *rust*. The oxide ions can be regarded as

FIGURE 13.19 Steel girders are galvanized by immersion in a bath of molten zinc.

coming from deprotonation of water molecules and as immediately forming the hydrated solid by precipitation with the Fe^{3+} ions produced in reaction F:

$$4\,H_2O(l) + 2\,Fe^{3+}(aq) \longrightarrow 6\,H^+(aq) + Fe_2O_3\cdot H_2O(s) \qquad \textbf{(G)}$$

This step restores the $H^+(aq)$ ions needed for reaction E, and so hydrogen ions function as a catalyst. The removal of Fe^{3+} ions from solution drives the reaction forward. The overall process is the sum of reactions E, F, and G:

$$2\,Fe(s) + \tfrac{3}{2}\,O_2(g) + H_2O(l) \longrightarrow Fe_2O_3\cdot H_2O(s)$$

Water is more highly conducting when it has dissolved ions, and the formation of rust is then accelerated. That is one reason why the salt air of coastal cities and salt used for de-icing highways is so damaging to exposed metal.

Because corrosion is electrochemical, we can use our knowledge of redox reactions to combat it. The simplest way to prevent corrosion is to protect the surface of the metal from exposure to air and water by painting. A method that achieves greater protection is to **galvanize** the metal, coating it with an unbroken film of zinc (Fig. 13.19). Zinc lies below iron in the electrochemical series; so, if a scratch exposes the metal beneath, the more strongly reducing zinc releases electrons to the iron. As a result, the zinc, not the iron, is oxidized. The zinc itself survives exposure on the unbroken surface because it is **passivated,** protected from further reaction, by a protective oxide. In general, the oxide of any metal that takes up more space than does the metal that it replaces acts as a **protective oxide**, an oxide that protects the metal from further oxidation. Zinc and chromium both form low-density protective oxides that can protect iron from oxidation.

It is not possible to galvanize large metal structures, such as ships, underground pipelines, gasoline storage tanks, and bridges, but **cathodic protection** can be used. For example, a block of a more strongly reducing metal than iron, typically zinc or magnesium, can be buried in moist soil and connected to an underground pipeline (Fig. 13.20). The block of magnesium is oxidized preferentially and supplies electrons to the iron for the reduction of oxygen. The block, which is called a **sacrificial anode,** protects the pipeline and is inexpensive to replace. For similar reasons, automobiles generally have negative ground systems as part of their electrical circuitry, which means that the body of the car is connected to the anode of the battery. The decay of the anode in the battery is the sacrifice that helps preserve the vehicle itself.

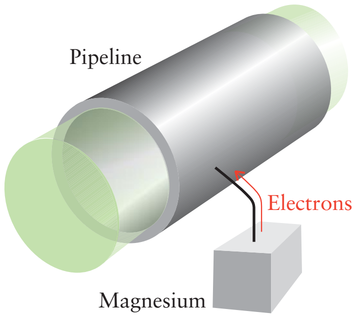

FIGURE 13.20 In the cathodic protection of a buried pipeline or other large metal construction, the artifact is connected to a number of buried blocks of metal, such as magnesium or zinc. The sacrificial anodes (the magnesium block in this illustration) supply electrons to the pipeline (the cathode of the cell), thereby preserving it from oxidation.

A common means of protecting the steel bodies of automobiles and trucks is through *cationic electrodeposition* coatings. In this process, a corrosion-resistant primer is deposited electrochemically on the automobile body, which serves as the cathode for the process. For many years lead(IV) oxide was used to provide this corrosion protection. However, lead is toxic and concerns for environmental pollution stimulated research into alternative metals for cationic electrodeposition coatings. Eventually it was

discovered that yttrium oxide also offers corrosion resistance and, in fact, is twice as effective as lead. Yet yttrium is nontoxic and its oxide is a ceramic. Thus, the oxide is insoluble in water and is not spread into the environment through waterways.

Self-Test 13.17A Which of the following procedures helps to prevent the corrosion of an iron rod in water: (a) decreasing the concentration of oxygen in the water; (b) painting the rod?

[***Answer:*** Both]

Self-Test 13.17B Which of the following elements can act as a sacrificial anode for iron: (a) copper; (b) aluminum; (c) tin?

The corrosion of iron is accelerated by the presence of oxygen, moisture, and salt. Corrosion can be inhibited by coating the surface with paint or zinc or by using cathodic protection.

13.15 Practical Cells

An important application of galvanic cells is their use as the portable power sources called batteries. An ideal battery should be inexpensive, portable, safe to use, and environmentally benign. It should also maintain a potential difference that is stable with the passage of time (Table 13.2). Both the mass and the volume of a battery are critical parameters. The electrolyte in a battery uses as little water as possible, both to reduce leakage of the electrolyte and to keep the mass low. Much of the research on batteries deals with raising the *specific energy* (the energy that it can generate divided by its mass), typically expressed in kilowatt-hours per kilogram, $kW{\cdot}h{\cdot}kg^{-1}$.

$1\ kW{\cdot}h = (10^3\ J{\cdot}s^{-1}) \times (3600\ s) = 3.6 \times 10^6\ J = 3.6\ MJ$ exactly.

A **primary cell** is a galvanic cell with the reactants sealed inside at manufacture. It cannot be recharged; when it runs down, it is discarded. A **fuel cell** is like a primary cell, but the reactants are continuously supplied (Box 13.1).

TABLE 13.2 Reactions in Commercial Batteries*

Primary cells		
dry	$Zn(s)\|ZnCl_2(aq), NH_4Cl(aq)\|MnO(OH)(s)\|MnO_2(s)\|graphite$	1.5 V
	Anode: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2\ e^-$	
	followed by $Zn^{2+}(aq) + 4\ NH_3(aq) \longrightarrow [Zn(NH_3)_4]^{2+}(aq)$	
	Cathode: $MnO_2(s) + H_2O(l) + e^- \longrightarrow MnO(OH)(s) + OH^-(aq)$	
	followed by $NH_4^+(aq) + OH^-(aq) \longrightarrow H_2O(l) + NH_3(aq)$	
alkaline	$Zn(s)\|ZnO(s)\|OH^-(aq)\|Mn(OH)_2(s)\|MnO_2(s)\|graphite$	1.5 V
	Anode: $Zn(s) + 2\ OH^-(aq) \longrightarrow ZnO(s) + H_2O(l) + 2\ e^-$	
	Cathode: $MnO_2(s) + 2\ H_2O(l) + 2\ e^- \longrightarrow Mn(OH)_2(s) + 2\ OH^-(aq)$	
silver	$Zn(s)\|ZnO(s)\|KOH(aq)\|Ag_2O(s)\|Ag(s)\|steel$	1.6 V
	Anode: $Zn(s) + 2\ OH^-(aq) \longrightarrow ZnO(s) + H_2O(l) + 2\ e^-$	
	Cathode: $Ag_2O(s) + H_2O(l) + 2\ e^- \longrightarrow 2\ Ag(s) + 2\ OH^-(aq)$	
Secondary cells		
lead–acid	$Pb(s)\|PbSO_4(s)\|H^+(aq), HSO_4^-(aq)\|PbO_2(s)\|PbSO_4(s)\|Pb(s)$	2 V
	Anode: $Pb(s) + HSO_4^-(aq) \longrightarrow PbSO_4(s) + H^+(aq) + 2\ e^-$	
	Cathode: $PbO_2(s) + 3\ H^+(aq) + HSO_4^-(aq) + 2\ e^- \longrightarrow PbSO_4(s) + 2\ H_2O(l)$	
nicad	$Cd(s)\|Cd(OH)_2(s)\|KOH(aq)\|Ni(OH)_3(s)\|Ni(OH)_2(s)\|Ni(s)$	1.25 V
	Anode: $Cd(s) + 2\ OH^-(aq) \longrightarrow Cd(OH)_2(s) + 2\ e^-$	
	Cathode: $2\ Ni(OH)_3(s) + 2\ e^- \longrightarrow 2\ Ni(OH)_2(s) + 2\ OH^-(aq)$	
NiMH	$M(s)\|MH(s)\|KOH(aq)\|NiOOH(s)\|Ni(OH)_2(s)\|Ni(s)$	1.2 V
	Anode: $MH(s)^\dagger + OH^-(aq) \longrightarrow M(s) + H_2O(l) + e^-$	
	Cathode: $NiOOH(s) + H_2O(l) + e^- \longrightarrow Ni(OH)_2(s) + OH^-$	
sodium–sulfur	$Na(l)\|Na^+(ceramic\ electrolyte), S^{2-}(ceramic\ electrolyte)\|S_8(l)$	2.2 V
	Anode: $2\ Na(l) \longrightarrow 2\ Na^+(electrolyte) + 2\ e^-$	
	Cathode: $S_8(l) + 16\ e^- \longrightarrow 8\ S^{2-}(electrolyte)$	

*Cell notation is described in Section 13.5.
†The metal in a nickel–metal hydride battery is usually a complex alloy of several metals, such as Cr, Ni, Co, V, Ti, Fe, and Zr.

A *dry cell* is the primary cell used in most common applications, such as portable media players, remote controls, and flashlights (Fig. 13.21). Its familiar cylindrical zinc container serves as the anode; in the center is the cathode, a carbon rod. The interior of the container is lined with paper that serves as the porous barrier. The electrolyte is a moist paste of ammonium chloride, manganese(IV) oxide, finely granulated carbon, and an inert filler, usually starch. The ammonia provided by the ammonium ions forms the complex ion $Zn(NH_3)_4^{2+}$ with the Zn^{2+} ions and prevents their buildup and a consequent reduction of the potential.

Two primary cells that provide a more stable and longer-lasting potential than the dry cell are the alkaline cell and silver cell. An *alkaline cell* is similar to a dry cell but uses an alkaline electrolyte, with which the zinc electrode does not readily react when the battery is not in use. As a result, alkaline cells have longer lives than dry cells. They are used in smoke detectors and backup power supplies. A *silver cell* has a cathode made of solid Ag_2O and Ag. The relatively high potential of a silver cell, with its solid reactants and products, is maintained with great reliability over long periods of time and the cell can be manufactured in very small sizes. These features make it desirable for medical implants such as pacemakers, for hearing aids, and for cameras.

Secondary cells are galvanic cells that must be charged before they can be used; this type of cell is normally rechargeable. The batteries used in portable computers and automobiles are secondary cells. In the charging process, an external source of electricity reverses the spontaneous cell reaction and creates a nonequilibrium mixture of reactants. After charging, the cell can again produce electricity.

The *lead-acid cell* of an automobile battery is a secondary cell that contains several grids that act as electrodes (Fig. 13.22). Although it has a low specific energy, because the total surface area of these grids is large, the battery can generate large currents for short periods, such as the time needed for starting an engine. The electrodes are initially a hard lead–antimony alloy covered with a paste of lead(II) sulfate. The electrolyte is dilute sulfuric acid. During the first charging, some of the lead(II) sulfate is reduced to lead on one of the electrodes; that electrode will act as the anode during discharge. Simultaneously, during charging, lead(II) sulfate is oxidized to lead(IV) oxide on the electrode that will later act as the cathode during discharge. The lead–acid cell, which has a potential of 2 V, is used in a series of six cells to provide a 12-V source of power for starting the engine in most vehicles and as the main power source in many electric vehicles.

Hybrid vehicles make use of the rechargeable *nickel–metal hydride (NiMH) cell* to supplement energy provided by burning gasoline. In this type of battery, hydrogen is stored in the form of a metal hydride, using a heterogeneous alloy of several metals, commonly including titanium, vanadium, chromium, and nickel. The advantages include low mass, high energy density (the energy that it can generate divided by its volume), long shelf life, high current load capability, rapid charging, and good capacity (long time between charges). Because the materials are nontoxic, disposal of the batteries does not generate environmental problems.

The *lithium-ion cell* is used in laptop computers and many media players, because it can be recharged many times. This type of battery has an electrolyte consisting of polypropylene oxide or polyethylene oxide mixed with molten lithium salts and then allowed to cool. The resulting rubbery materials serve as good conductors of Li^+ ions. The low mass density of lithium gives it the highest available energy density, and lithium's very negative electrode potential provides a cell potential as high as 4 V.

A *sodium–sulfur cell* is one of the more startling batteries (Fig. 13.23). It has liquid reactants (sodium and sulfur) and a solid electrolyte (a porous aluminum oxide ceramic); it must operate at a temperature of about 320°C; and it is highly dangerous in case of breakage. Because sodium has a low density, these cells have a very high specific energy. Their most common application is to power electric vehicles. Once the vehicle is operating, the heat generated by the battery is sufficient to maintain the temperature.

Practical galvanic cells can be classified as primary cells (reactants are sealed inside in a charged state), secondary cells (can be recharged), and fuel cells.

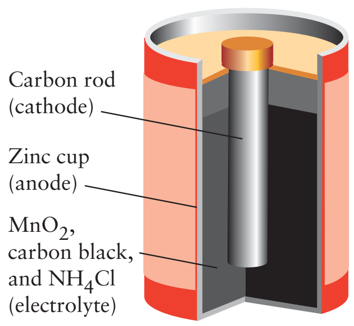

FIGURE 13.21 A commercial dry cell. The dry cell is also called the Leclanché cell, for Georges Leclanché, the French engineer who invented it in about 1866. The electrolyte is a moist paste.

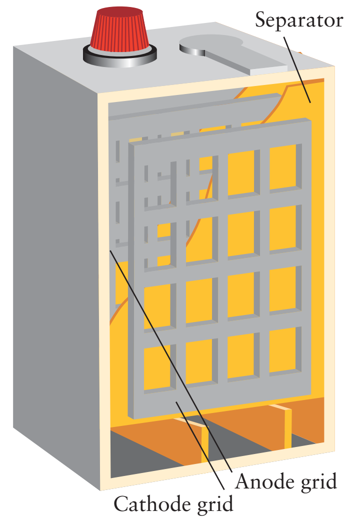

FIGURE 13.22 A lead–acid battery consists of a number of cells in series. A series of six cells produces about 12 V.

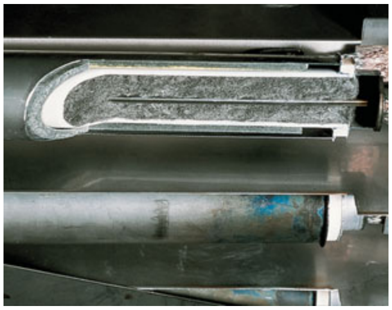

FIGURE 13.23 A sodium–sulfur battery used in an electric vehicle.

BOX 13.1 FRONTIERS OF CHEMISTRY: FUEL CELLS

Spacecraft need a source of electrical power and astronauts need enough water for drinking and washing. Because the mass of spacecraft that are built to lift off from planets must be kept as low as possible, most batteries—which usually provide energy from the oxidation of a metal—would be too heavy. Electricity can be obtained from combustion reactions by burning a fuel to create heat, which runs a generator. However, producing electricity from burning fuels is very inefficient because energy is wasted as heat.

An answer to the problem already existed. Francis Bacon, a British scientist and engineer, had developed an idea proposed by Sir William Grove in 1839. A **fuel cell** generates electricity directly from a chemical reaction, as in a battery, but uses reactants that are supplied continuously, as in an engine. A fuel cell that runs on hydrogen and oxygen is currently installed on the space shuttle (see Fig. L.1). An advantage of this fuel cell is that the only product of the cell reaction, water, can be used for life support.

In a simple version of a fuel cell, a fuel such as hydrogen gas is passed over a platinum electrode, oxygen is passed over the other, similar electrode, and the electrolyte is aqueous potassium hydroxide. A porous membrane that is permeable to ions separates the two electrode compartments. Many varieties of fuel cells are possible, and in some the electrolyte is a solid polymer membrane or a ceramic (see Section 6.11). Three of the most promising fuel cells are the alkali fuel cell, the phosphoric acid fuel cell, and the methanol fuel cell.

The *hydrogen–oxygen cell* used in the space shuttle is called an *alkali fuel cell*, because it has an alkaline electrolyte:

Anode: $2\,H_2(g) + 4\,OH^-(aq) \longrightarrow 4\,H_2O(l) + 4\,e^-$

Electrolyte: $KOH(aq)$

Cathode: $O_2(g) + 4\,e^- + 2\,H_2O(l) \longrightarrow 4\,OH^-(aq)$

Although its cost prohibits its use in many applications, the alkali fuel cell is the primary fuel cell used in the aerospace industry.

An acid electrolyte may also be used, as in a *phosphoric acid fuel cell*:

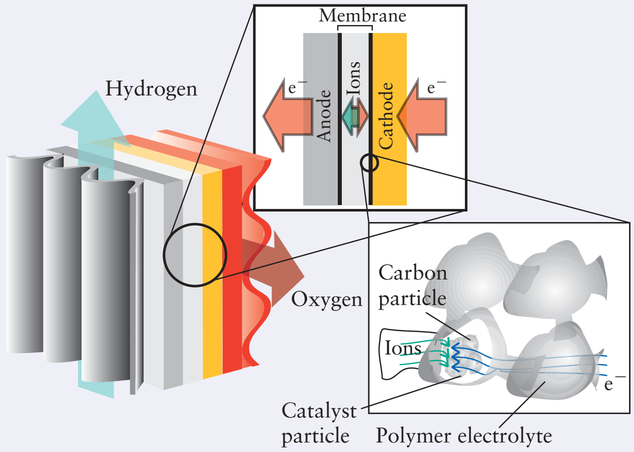
Anode: $2\,H_2(g) \longrightarrow 4\,H^+(aq) + 4\,e^-$

Electrolyte: $H_3PO_4(aq)$

Cathode: $O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l)$

This fuel cell has shown promise for *combined heat and power systems* (CHP systems). In such systems, the waste heat is used to heat buildings or to do work. Efficiency in a CHP plant can reach 80%. These plants could replace heating plants and power sources in colleges and universities, hotels, and apartment buildings.

Although hydrogen gas is an attractive fuel, it has disadvantages for mobile applications: it is difficult to store and dangerous to handle. One possibility for portable fuel cells is to store the hydrogen in nanotubes made of carbon, silicon, or compounds



A proton exchange membrane is used in both hydrogen and methanol fuel cells. It allows protons but not electrons to travel through it: the protons flow through the porous membrane to the cathode, where they combine with oxygen to form water, while the electrons flow through an external circuit. Several layers of cells are combined to generate the power required.

SKILLS YOU SHOULD HAVE MASTERED

- ❑ 1 Balance chemical equations for redox reactions by the half-reaction method (Toolbox 13.1 and Examples 13.1 and 13.2).
- ❑ 2 Estimate the reaction Gibbs free energy from a cell potential (Example 13.3).
- ❑ 3 Write the cell diagram for a redox reaction (Self-Test 13.4).
- ❑ 4 Write the chemical equation for a cell reaction, given the cell diagram (Toolbox 13.2 and Example 13.4).
- ❑ 5 Determine the standard potential of an electrode from a cell potential (Example 13.5).
- ❑ 6 Calculate the standard potential of a redox couple from two others relating to different oxidation states (Example 13.6).
- ❑ 7 Predict the spontaneous direction of a redox reaction by using the electrochemical series (Example 13.7).
- ❑ 8 Calculate the equilibrium constant for a reaction from the standard cell potential (Toolbox 13.3 and Example 13.8).
- ❑ 9 Use the Nernst equation to predict a cell potential for an arbitrary composition of the cell (Examples 13.9 and 13.10).
- ❑ 10 Predict the likely products of electrolysis of an aqueous solution from standard potentials (Example 13.11).
- ❑ 11 Calculate the amount of product produced from electrolysis or the time required for electrolysis (Toolbox 13.4 and Examples 13.12 and 13.13).
- ❑ 12 Describe corrosion and means for protecting iron from corrosion (Section 13.14).
- ❑ 13 Describe the operation of commercial practical cells (Section 13.15).

This automobile is powered by a hydrogen fuel cell with a proton exchange membrane. Its operation is pollution free, because the only product of the combustion is water.

such as WS_2 or TiO_2. Hydrogen molecules are readily adsorbed on the surfaces of these materials and nanotubes have very large surface areas. Carbon nanofibers in herringbone patterns have been shown to store huge amounts of hydrogen and to result in energy densities twice that of gasoline. Another option is the use of organometallic materials or inorganic hydrides, such as sodium aluminum hydride, $NaAlH_4$, doped with titanium.

Until these materials have been developed, one attractive fuel is methanol, which is easy to handle and is rich in hydrogen atoms:

Anode: $CH_3OH(l) + 6\ OH^-(aq) \longrightarrow 5\ H_2O(l) + CO_2(g) + 6\ e^-$

Electrolyte: polymeric materials

Cathode: $O_2(g) + 4\ e^- + 2\ H_2O(l) \longrightarrow 4\ OH^-(aq)$

A disadvantage of methanol is the phenomenon of "electro-osmotic drag" in which protons moving through the polymer proton exchange electrolyte membrane that separates the anode and cathode carry water and methanol with them into the cathode compartment. In the cathode, the potential is sufficient to oxidize CH_3OH to CO_2, thereby reducing the efficiency of the cell. One solution might be to find a material for the cathode that is selective to oxygen reduction so that any methanol that leaks in is not oxidized.

An exciting emerging technology is the *biofuel cell*. A biofuel cell is like a conventional fuel cell; however, in place of a platinum catalyst, it uses enzymes or even whole organisms. The electricity is extracted through organic molecules that can support the transfer of electrons. One application is as the power source for medical implants, such as pacemakers, perhaps by using the glucose present in the bloodstream as the fuel.

? HOW MIGHT YOU CONTRIBUTE?

Fuel cell technologies developed for aerospace have the potential to change the way we live on Earth. Automobiles powered by hydrogen fuel cells are already being manufactured (see the illustration). However, there are many obstacles that must be overcome before fuel cells reach their potential to provide us with pollution-free energy. The hydrogen fuel cells are the most attractive, because of their use of a renewable fuel. Hydrogen can be obtained from the water in the oceans. The challenge is to extract it from seawater by using solar energy and to find safe means of transportation and storage. Many practical problems with fuel cells also need to be solved, such as controlling corrosion by electrolytes and reducing the cell size and operating temperature. The development of biofuel cells is also potentially of great significance.

EXERCISES

Assume a temperature of 25°C (298 K) for the following exercises unless instructed otherwise.

Redox Equations

13.1 The following redox reaction is used in acidic solution in the Breathalyzer test to determine the level of alcohol in the blood:

$$H^+(aq) + Cr_2O_7^{2-}(aq) + C_2H_5OH(aq) \longrightarrow Cr^{3+}(aq) + C_2H_4O(aq) + H_2O(l)$$

(a) Identify the elements undergoing changes in oxidation state and indicate the initial and final oxidation numbers for these elements. (b) Write and balance the oxidation half-reaction. (c) Write and balance the reduction half-reaction. (d) Combine the half-reactions to produce a balanced redox equation.

13.2 The following redox reaction is used to prepare orthotelluric acid:

$$Te(s) + ClO_3^-(aq) + H_2O(l) \longrightarrow H_6TeO_6(aq) + Cl_2(g)$$

(a) Identify the elements undergoing changes in oxidation state and indicate the initial and final oxidation numbers for these elements. (b) Write and balance the oxidation half-reaction. (c) Write and balance the reduction half-reaction. (d) Combine the half-reactions to produce a balanced redox equation.

13.3 Balance each of the following skeletal equations by using oxidation and reduction half-reactions. All the reactions take place in acidic solution. Identify the oxidizing agent and reducing agent in each reaction.

(a) Reaction of thiosulfate ion with chlorine gas:
$Cl_2(g) + S_2O_3^{2-}(aq) \longrightarrow Cl^-(aq) + SO_4^{2-}(aq)$

(b) Action of the permanganate ion on sulfurous acid:
$MnO_4^-(aq) + H_2SO_3(aq) \longrightarrow Mn^{2+}(aq) + HSO_4^-(aq)$

(c) Reaction of hydrosulfuric acid with chlorine:
$H_2S(aq) + Cl_2(g) \longrightarrow S(s) + Cl^-(aq)$

(d) Reaction of chlorine in water:
$Cl_2(g) \longrightarrow HClO(aq) + Cl^-(aq)$

13.4 Balance each of the following skeletal equations by using oxidation and reduction half-reactions. All the reactions take place in acidic solution. Identify the oxidizing agent and reducing agent in each reaction.
(a) Reaction of the selenite ion with chlorate ion:
$SeO_3^{2-}(s) + ClO_3^-(aq) \longrightarrow SeO_4^{2-}(aq) + Cl_2(g)$
(b) Formation of propanone (acetone), which is used in nail polish remover, from isopropanol (rubbing alcohol) by the action of dichromate ion:
$C_3H_7OH(aq) + Cr_2O_7^{2-}(aq) \longrightarrow Cr^{3+}(aq) + C_3H_6O(aq)$
(c) Reaction of gold with selenic acid:
$Au(s) + SeO_4^{2-}(aq) \longrightarrow Au^{3+}(aq) + SeO_3^{2-}(aq)$
(d) Preparation of stibnine from antimonic acid:
$H_2SbO_3^{2-}(s) + Zn(s) \longrightarrow SbH_3(aq) + Zn^{2+}(aq)$

13.5 Balance each of the following skeletal equations by using oxidation and reduction half-reactions. All the reactions take place in basic solution. Identify the oxidizing agent and reducing agent in each reaction.
(a) Action of ozone on bromide ions:
$O_3(aq) + Br^-(aq) \longrightarrow O_2(g) + BrO_3^-(aq)$
(b) Reaction of bromine in water:
$Br_2(l) \longrightarrow BrO_3^-(aq) + Br^-(aq)$
(c) Formation of chromate ions from chromium(III) ions:
$Cr^{3+}(aq) + MnO_2(s) \longrightarrow Mn^{2+}(aq) + CrO_4^{2-}(aq)$
(d) Reaction of elemental phosphorus to form phosphine, PH_3, a poisonous gas with the odor of decaying fish:
$P_4(s) \longrightarrow H_2PO_2^-(aq) + PH_3(g)$

13.6 Balance each of the following skeletal equations by using oxidation and reduction half-reactions. All the reactions take place in basic solution. Identify the oxidizing agent and reducing agent in each reaction.
(a) Production of chlorite ions from dichlorine heptoxide:
$Cl_2O_7(g) + H_2O_2(aq) \longrightarrow ClO_2^-(aq) + O_2(g)$
(b) Action of permanganate ions on sulfide ions:
$MnO_4^-(aq) + S^{2-}(aq) \longrightarrow S(s) + MnO_2(s)$
(c) Reaction of hydrazine with chlorate ions:
$N_2H_4(g) + ClO_3^-(aq) \longrightarrow NO(g) + Cl^-(aq)$
(d) Reaction of plumbate ions and hypochlorite ions:
$Pb(OH)_4^{2-}(aq) + ClO^-(aq) \longrightarrow PbO_2(s) + Cl^-(aq)$

13.7 The compound P_4S_3 is oxidized by nitrate ions in acid solution to give phosphoric acid, sulfate ions, and nitric oxide, NO. Write the balanced equation for each half-reaction and the overall equation for the reaction.

13.8 Iron(II) hydrogen phosphite, $FeHPO_3$, is oxidized by hypochlorite ions in basic solution. The products are chloride ion, phosphate ion, and iron(III) hydroxide. Write the balanced equation for each half-reaction and the overall equation for the reaction.

Galvanic Cells

13.9 Calculate the standard reaction Gibbs free energy for the following cell reactions:
(a) $2\,Ce^{4+}(aq) + 3\,I^-(aq) \longrightarrow 2\,Ce^{3+}(aq) + I_3^-(aq)$,
$E_{cell}° = +1.08$ V
(b) $6\,Fe^{3+}(aq) + 2\,Cr^{3+}(aq) + 7\,H_2O(l) \longrightarrow 6\,Fe^{2+}(aq) + Cr_2O_7^{2-}(aq) + 14\,H^+(aq)$, $E_{cell}° = -1.29$ V

13.10 Calculate the standard reaction Gibbs free energy for the following cell reactions:
(a) $3\,Cr^{3+}(aq) + Bi(s) \longrightarrow 3\,Cr^{2+}(aq) + Bi^{3+}(aq)$,
$E_{cell}° = -0.61$ V
(b) $Mg(s) + 2\,H_2O(l) \longrightarrow Mg^{2+}(aq) + H_2(g) + 2\,OH^-(aq)$,
$E_{cell}° = +2.36$ V

13.11 Write the half-reactions and the balanced equation for the cell reaction for each of the following galvanic cells:
(a) $Ni(s)|Ni^{2+}(aq)||Ag^+(aq)|Ag(s)$
(b) $C(gr)|H_2(g)|H^+(aq)||Cl^-(aq)|Cl_2(g)|Pt(s)$
(c) $Cu(s)|Cu^{2+}(aq)||Ce^{4+}(aq),Ce^{3+}(aq)|Pt(s)$
(d) $Pt(s)|O_2(g)|H^+(aq)||OH^-(aq)|O_2(g)|Pt(s)$
(e) $Pt(s)|Sn^{4+}(aq),Sn^{2+}(aq)||Cl^-(aq)|Hg_2Cl_2(s)|Hg(l)$

13.12 Write the half-reactions and the balanced equation for the cell reaction for each of the following galvanic cells:
(a) $Cu(s)|Cu^{2+}(aq)||Cu^+(aq)|Cu(s)$
(b) $Cr(s)|Cr^{2+}(aq)||Au^{3+}(aq)|Au(s)$
(c) $Ag(s)|AgI(s)|I^-(aq)||Cl^-(aq)|AgCl(s)|Ag(s)$
(d) $Hg(l)|Hg_2Cl_2(s)|Cl^-(aq)||Cl^-(aq)|AgCl(s)|Ag(s)$
(e) $Hg(l)|Hg_2^{2+}(aq)||MnO_4^-(aq),Mn^{2+}(aq),H^+(aq)|Pt(s)$

13.13 Write the half-reactions, the balanced equation for the cell reaction, and the cell diagram for each of the following skeletal equations:
(a) $Ni^{2+}(aq) + Zn(s) \longrightarrow Ni(s) + Zn^{2+}(aq)$
(b) $Ce^{4+}(aq) + I^-(aq) \longrightarrow I_2(s) + Ce^{3+}(aq)$
(c) $Cl_2(g) + H_2(g) \longrightarrow HCl(aq)$
(d) $Au^+(aq) \longrightarrow Au(s) + Au^{3+}(aq)$

13.14 Write the half-reactions, the balanced equation for the cell reaction, and the cell diagram for each of the following skeletal equations:
(a) $Mn(s) + Ti^{2+}(aq) \longrightarrow Mn^{2+}(aq) + Ti(s)$
(b) $Fe^{3+}(aq) + H_2(g) \longrightarrow Fe^{2+}(aq) + H^+(aq)$
(c) $Cu^+(aq) \longrightarrow Cu(s) + Cu^{2+}(aq)$
(d) $MnO_4^-(aq) + H^+(aq) + Cl^-(aq) \longrightarrow Cl_2(g) + Mn^{2+}(aq) + H_2O(l)$

13.15 Write the half-reactions and devise a galvanic cell (write a cell diagram) to study each of the following reactions:
(a) $AgBr(s) \rightleftharpoons Ag^+(aq) + Br^-(aq)$, a solubility equilibrium
(b) $H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$, the Brønsted neutralization reaction
(c) $Cd(s) + 2\,Ni(OH)_3(s) \longrightarrow Cd(OH)_2(s) + 2\,Ni(OH)_2(s)$, the reaction in the nickel–cadmium cell

13.16 Write balanced half-reactions and devise a galvanic cell (write a cell diagram) to study each of the following reactions:
(a) $Pb(NO_3)_2(aq) + K_2SO_4(aq) \longrightarrow PbSO_4(s) + 2\,KNO_3(aq)$, a precipitation reaction
(b) $OH^-(aq, \text{concentrated}) \longrightarrow OH^-(aq, \text{dilute})$
(c) $Na(s) + S(s) \longrightarrow Na^+(l) + S^{2-}(l)$, the reaction in a sodium–sulfur cell

13.17 (a) Write balanced half-reactions for the redox reaction of an acidified solution of potassium permanganate and iron(II) chloride. (b) Write the balanced equation for the cell reaction and devise a galvanic cell to study the reaction (write its cell diagram).

13.18 (a) Write balanced half-reactions for the redox reaction between sodium perchlorate and copper(I) nitrate in an acidic solution. (b) Write the balanced equation for the cell reaction and devise a galvanic cell to study the reaction (write its cell diagram).

13.19 Predict the standard potential of each of the following galvanic cells:
(a) $Pt(s)|Cr^{3+}(aq),Cr^{2+}(aq)||Cu^{2+}(aq)|Cu(s)$
(b) $Ag(s)|AgI(s)|I^-(aq)||Cl^-(aq)|AgCl(s)|Ag(s)$
(c) $Hg(l)|Hg_2Cl_2(s)|Cl^-(aq)||Hg_2^{2+}(aq)|Hg(l)$
(d) $C(gr)|Sn^{4+}(aq),Sn^{2+}(aq)||Pb^{4+}(aq),Pb^{2+}(aq)|Pt(s)$

13.20 Predict the standard potential of each of the following galvanic cells:
(a) $Pt(s)|Fe^{3+}(aq),Fe^{2+}(aq)||Ag^+(aq)|Ag(s)$
(b) $U(s)|U^{3+}(aq)||V^{2+}(aq)|V(s)$
(c) $Sn(s)|Sn^{2+}(aq)||Sn^{4+}(aq), Sn^{2+}(aq)|Pt(s)$
(d) $Cu(s)|Cu^{2+}(aq)||Au^+(aq)|Au(s)$

13.21 For each reaction that is spontaneous under standard conditions, write a cell diagram, determine the standard cell potential, and calculate $\Delta G°$ for the reaction:
(a) $2\ NO_3^-(aq) + 8\ H^+(aq) + 6\ Hg(l) \longrightarrow 3\ Hg_2^{2+}(aq) + 2\ NO(g) + 4\ H_2O(l)$
(b) $2\ Hg^{2+}(aq) + 2\ Br^-(aq) \longrightarrow Hg_2^{2+}(aq) + Br_2(l)$
(c) $Cr_2O_7^{2-}(aq) + 14\ H^+(aq) + 6\ Pu^{3+}(aq) \longrightarrow 6\ Pu^{4+}(aq) + 2\ Cr^{3+}(aq) + 7\ H_2O(l)$

13.22 Predict the standard cell potential and calculate the standard reaction Gibbs free energy for galvanic cells having the following cell reactions:
(a) $3\ Zn(s) + 2\ Bi^{3+}(aq) \longrightarrow 3\ Zn^{2+}(aq) + 2\ Bi(s)$
(b) $2\ H_2(g) + O_2(g) \longrightarrow 2\ H_2O(l)$ in acidic solution
(c) $2\ H_2(g) + O_2(g) \longrightarrow 2\ H_2O(l)$ in basic solution
(d) $3\ Au^+(aq) \longrightarrow 2\ Au(s) + Au^{3+}(aq)$

13.23 A student was given a standard $Cu(s)|Cu^{2+}(aq)$ half-cell and another half-cell containing an unknown metal M immersed in 1.00 M $M(NO_3)_2(aq)$. When the copper was connected as the anode at 25°C, the cell potential was found to be −0.689 V. What is the reduction potential for the unknown M^{2+}/M couple?

13.24 A student was given a standard $Fe(s)|Fe^{2+}(aq)$ half-cell and another half-cell containing an unknown metal M immersed in 1.00 M $MNO_3(aq)$. When these two half-cells were connected at 25°C, the complete cell functioned as a galvanic cell with $E_{cell} = +1.24$ V. The reaction was allowed to continue overnight and the two electrodes were weighed. The iron electrode was found to be lighter and the unknown metal electrode was heavier. What is the standard potential of the unknown M^+/M couple?

13.25 Arrange the following metals in order of increasing strength as reducing agents for species in aqueous solution: (a) Cu, Zn, Cr, Fe; (b) Li, Na, K, Mg; (c) U, V, Ti, Al; (d) Ni, Sn, Au, Ag.

13.26 Arrange the following species in order of increasing strength as oxidizing agents for species in aqueous solution: (a) Co^{2+}, Cl_2, Ce^{4+}, In^{3+}; (b) NO_3^-, ClO_4^-, HBrO, $Cr_2O_7^{2-}$, all in acidic solution; (c) O_2, O_3, HClO, and HBrO, all in acidic solution; (d) O_2, O_3, ClO^-, BrO^-, all in basic solution.

13.27 Using data available in Appendix 2B, calculate the standard potential for the half-reaction $U^{4+}(aq) + 4\ e^- \longrightarrow U(s)$.

13.28 Using data available in Appendix 2B, calculate the standard potential for the half-reaction $Ti^{3+}(aq) + 3\ e^- \longrightarrow Ti(s)$.

13.29 Suppose that each of the following pairs of redox couples is joined to form a galvanic cell that generates a current under standard conditions. Identify the oxidizing agent and the reducing agent, write a cell diagram, and calculate the standard cell potential. (a) Co^{2+}/Co and Ti^{3+}/Ti^{2+}; (b) La^{3+}/La and U^{3+}/U; (c) H^+/H_2 and Fe^{3+}/Fe^{2+}; (d) $O_3/O_2,OH^-$ and Ag^+/Ag.

13.30 Suppose that each of the following pairs of redox couples is joined to form a galvanic cell that generates a current under standard conditions. Identify the oxidizing agent and the reducing agent, write a cell diagram, and calculate the standard cell potential. (a) Pt^{2+}/Pt and $AgF/Ag,F^-$; (b) Cr^{3+}/Cr^{2+} and I_3^-/I^-; (c) H^+/H_2 and Ni^{2+}/Ni; (d) O_3/O_2, OH^- and $O_3,H^+/O_2$.

13.31 Identify the reactions with $K > 1$ in the following list and, for each such reaction, identify the oxidizing agent and calculate the standard cell potential.
(a) $Cl_2(g) + 2\ Br^-(aq) \longrightarrow 2\ Cl^-(aq) + Br_2(l)$
(b) $MnO_4^-(aq) + 8\ H^+(aq) + 5\ Ce^{3+}(aq) \longrightarrow 5\ Ce^{4+}(aq) + Mn^{2+}(aq) + 4\ H_2O(l)$
(c) $2\ Pb^{2+}(aq) \longrightarrow Pb(s) + Pb^{4+}(aq)$
(d) $2\ NO_3^-(aq) + 4\ H^+(aq) + Zn(s) \longrightarrow Zn^{2+}(aq) + 2\ NO_2(g) + 2\ H_2O(l)$

13.32 Identify the reactions with $K > 1$ among the following reactions and, for each such reaction, write balanced reduction and oxidation half-reactions. For those reactions, show that $K > 1$ by calculating the standard Gibbs free energy of the reaction. Use the smallest whole-number coefficients to balance the equations.
(a) $Mg^{2+}(aq) + Cu(s) \longrightarrow ?$
(b) $Al(s) + Pb^{2+}(aq) \longrightarrow ?$
(c) $Hg_2^{2+}(aq) + Ce^{3+}(aq) \longrightarrow ?$
(d) $Zn(s) + Sn^{2+}(aq) \longrightarrow ?$
(e) $O_2(g) + H^+(aq) + Hg(l) \longrightarrow ?$

13.33 (a) The standard Gibbs free energy of formation of $Tl^{3+}(aq)$ is $+215\ kJ{\cdot}mol^{-1}$ at 25°C. Calculate the standard potential of the Tl^{3+}/Tl couple. (b) Will Tl^+ disproportionate in aqueous solution?

13.34 The standard potential of the Al^{3+}/Al couple is −1.66 V. Calculate the standard Gibbs free energy of formation for $Al^{3+}(aq)$. Account for any differences between the standard Gibbs free energy of formation of $Tl^{3+}(aq)$ (see Exercise 13.33) and that of $Al^{3+}(aq)$.

13.35 Determine the equilibrium constants for the following reactions:

(a) $Mn(s) + Ti^{2+}(aq) \rightleftharpoons Mn^{2+}(aq) + Ti(s)$
(b) $In^{3+}(aq) + U^{3+}(aq) \rightleftharpoons In^{2+}(aq) + U^{4+}(aq)$

13.36 Determine the equilibrium constants for the following reactions:

(a) $2\ Fe^{3+}(aq) + H_2(g) \rightleftharpoons 2\ Fe^{2+}(aq) + 2\ H^+(aq)$
(b) $2\ Cr(s) + O_2(g) + 2\ H_2O(l) \rightleftharpoons 2\ Cr^{2+}(aq) + 4\ OH^-(aq)$

13.37 Calculate the reaction quotient, Q, for the cell reaction, given the measured values of the cell potential. Balance the chemical equations by using the smallest whole-number coefficients.

(a) $Pt(s)|Sn^{4+}(aq), Sn^{2+}(aq)||Pb^{4+}(aq), Pb^{2+}(aq)|C(gr)$, $E = +1.33$ V.
(b) $Pt(s)|O_2(g)|H^+(aq)||Cr_2O_7^{2-}(aq), H^+(aq), Cr^{3+}(aq)|Pt(s)$, $E = +0.10$ V.

13.38 Calculate the reaction quotient, Q, for the cell reaction, given the measured values of the cell potential. Balance the chemical equations by using the smallest whole-number coefficients.
(a) $Ag(s)|Ag^+(aq)||ClO_4^-(aq),H^+(aq),ClO_3^-(aq)|Pt(s)$, $E = +0.40$ V.
(b) $C(gr)|Cl_2(g)|Cl^-(aq)||Au^{3+}(aq)|Au(s)$, $E = 0.00$ V.

13.39 Calculate E for each of the following concentration cells:
(a) $Cu(s)|Cu^{2+}(aq,\ 0.0010\ mol{\cdot}L^{-1})||Cu^{2+}(aq,\ 0.010\ mol{\cdot}L^{-1})|\ Cu(s)$

(b) $Pt(s)|H_2(g, 1\ bar)|H^+(aq, pH = 4.0)||H^+(aq, pH = 3.0)|H_2(g, 1\ bar)|Pt(s)$

13.40 Determine the unknown concentration of the ion in each of the following cells:
(a) $Pb(s)|Pb^{2+}(aq, ?)||Pb^{2+}(aq, 0.10\ mol{\cdot}L^{-1})|Pb(s)$, $E = +0.050$ V.
(b) $Pt(s)|Fe^{3+}(aq, 0.10\ mol{\cdot}L^{-1}),Fe^{2+}(aq, 1.0\ mol{\cdot}L^{-1})||Fe^{3+}(aq, ?),Fe^{2+}(aq, 0.0010\ mol{\cdot}L^{-1})|Pt(s)$, $E = +0.10$ V.

13.41 Determine the potential of each of the following cells:
(a) $Pt(s)|H_2(g, 1.0\ bar)|HCl(aq, 0.075\ M)||HCl(aq, 1.0\ mol{\cdot}L^{-1})|H_2(g, 1.0\ bar)|Pt(s)$
(b) $Zn(s)|Zn^{2+}(aq, 0.37\ mol{\cdot}L^{-1})||Ni^{2+}(aq, 0.059\ mol{\cdot}L^{-1})|Ni(s)$
(c) $Pt(s)|Cl_2(g, 250\ Torr)|HCl(aq, 1.0\ M)||HCl(aq, 0.85\ M)|H_2(g, 125\ Torr)|Pt(s)$
(d) $Sn(s)|Sn^{2+}(aq, 0.277\ mol{\cdot}L^{-1})||Sn^{4+}(aq, 0.867\ mol{\cdot}L^{-1}), Sn^{2+}(aq, 0.55\ mol{\cdot}L^{-1})|Pt(s)$

13.42 Determine the potential of each of the following cells:
(a) $Cr(s)|Cr^{3+}(aq, 0.37\ mol{\cdot}L^{-1})||Pb^{2+}(aq, 9.5 \times 10^{-3}\ mol{\cdot}L^{-1})|Pb(s)$
(b) $Pt(s)|H_2(g, 2.0\ bar)|H^+(pH = 3.5)||Cl^-(aq, 0.75\ mol{\cdot}L^{-1})|Hg_2Cl_2(s)|Hg(l)$
(c) $C(gr)|Sn^{4+}(aq, 0.059\ mol{\cdot}L^{-1}),Sn^{2+}(aq, 0.059\ mol{\cdot}L^{-1})||Fe^{3+}(aq, 0.15\ mol{\cdot}L^{-1}),Fe^{2+}(aq, 0.15\ mol{\cdot}L^{-1})|Pt(s)$
(d) $Ag(s)|AgI(s)|I^-(aq, 0.025\ mol{\cdot}L^{-1})||Cl^-(aq, 0.67\ mol{\cdot}L^{-1})|AgCl(s)|Ag(s)$

13.43 Determine the unknown quantity in each of the following cells:
(a) $Pt(s)|H_2(g, 1.0\ bar)|H^+(pH = ?)||Cl^-(aq, 1.0\ mol{\cdot}L^{-1})|Hg_2Cl_2(s)|Hg(l)$, $E = +0.33$ V.
(b) $C(gr)|Cl_2(g, 1.0\ bar)|Cl^-(aq, ?)||MnO_4{}^-(aq, 0.010\ mol{\cdot}L^{-1}), H^+(pH = 4.0), Mn^{2+}(aq, 0.10\ mol{\cdot}L^{-1})|Pt(s)$, $E = -0.30$ V.

13.44 Determine the unknown quantity in each of the following cells:
(a) $Pt(s)|H_2(g, 1.0\ bar)|H^+(pH = ?)||Cl^-(aq,1.0\ mol{\cdot}L^{-1})|AgCl(s)|Ag(s)$, $E = +0.40$ V.
(b) $Pb(s)|Pb^{2+}(aq, ?)||Ni^{2+}(aq, 0.20\ mol{\cdot}L^{-1})|Ni(s)$, $E = +0.050$ V.

13.45 A tin electrode in 0.015 M $Sn(NO_3)_2$(aq) is connected to a hydrogen electrode in which the pressure of H_2 is 1.0 bar. If the cell potential is 0.061 V at 25°C, what is the pH of the electrolyte at the hydrogen electrode?

13.46 A lead electrode in 0.010 M $Pb(NO_3)_2$(aq) is connected to a hydrogen electrode in which the pressure of H_2 is 1.0 bar. If the cell potential is 0.057 V at 25°C, what is the pH of the electrolyte at the hydrogen electrode?

13.47 (a) Using data from Appendix 2B, calculate the solubility product of Hg_2Cl_2. (b) Compare this number with the value listed in Table 12.4 and comment on the difference.

13.48 (a) The standard potential of the reduction of Ag_2CrO_4 to Ag(s) and chromate ions is +0.446 V. Write the balanced half-reaction for the reduction of silver chromate. (b) Using the data from part (a) and Appendix 2B, calculate the solubility product of Ag_2CrO_4(s).

13.49 Consider the cell $Ag(s)|Ag^+(aq, 5.0\ mmol{\cdot}L^{-1})||Ag^+(aq, 0.15\ mol{\cdot}L^{-1})|Ag(s)$. Can this cell do work? If so, what is the maximum work that it can perform (per mole of Ag)?

13.50 Consider the cell $Ag(s)|Ag^+(aq, 2.1 \times 10^{-4}\ mol{\cdot}L^{-1})||Pb^{2+}(aq, 0.10\ mol{\cdot}L^{-1})|Pb(s)$. (a) Can this cell do work? If so, what is the maximum work that it can perform (per mole of Pb)? (b) What is the value of ΔH for the cell reaction and what is the sign of ΔS?

13.51 Suppose the reference electrode for Table 13.1 were the standard calomel electrode, $Hg_2Cl_2/Hg,Cl^-([Cl^-] = 1.00\ mol{\cdot}L^{-1})$ with its $E°$ set equal to 0. Under this system, what would be the potential for (a) the standard hydrogen electrode; (b) the standard Cu^{2+}/Cu redox couple?

13.52 Consider the question posed in Exercise 13.51 except that a saturated calomel electrode (the solution is saturated with KCl instead of having $[Cl^-] = 1.00\ mol{\cdot}L^{-1}$) is used in place of the standard calomel electrode. How will this replacement change the answers given in Exercise 13.51? The solubility of KCl is $35\ g{\cdot}(100\ mL\ H_2O)^{-1}$.

Electrolysis

For the exercises in this section, base your answers on the potentials listed in Table 13.1 or Appendix 2B, with the exception of the reduction and oxidation of water at pH = 7:

$$2\,H_2O(l) + 2\,e^- \longrightarrow H_2(g) + 2\,OH^-(aq) \qquad E = -0.42 \text{ V at pH} = 7$$

$$O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l) \qquad E = +0.82 \text{ V at pH} = 7$$

Ignore other factors such as passivation and overpotential.

13.53 A 1.0 M $NiSO_4$(aq) solution was electrolyzed by using inert electrodes. Write (a) the cathode reaction; (b) the anode reaction. (c) With no overpotential or passivity at the electrodes, what is the minimum potential that must be supplied to the cell for the onset of electrolysis?

13.54 A 1.0 M KBr(aq) solution was electrolyzed by using inert electrodes. Write (a) the cathode reaction; (b) the anode reaction. (c) With no overpotential or passivity at the electrodes, what is the minimum potential that must be supplied to the cell for the onset of electrolysis?

13.55 Aqueous solutions of (a) Mn^{2+}; (b) Al^{3+}; (c) Ni^{2+}; (d) Au^{3+} with concentrations of $1.0\ mol{\cdot}L^{-1}$ are electrolyzed at pH = 7. Determine whether the metal ion or water will be reduced at the cathode.

13.56 The anode of an electrolytic cell was constructed from (a) Cr; (b) Pt; (c) Cu; (d) Ni. Determine whether oxidation of the electrode or of water will take place at the anode when the electrolyte consists of a 1.0 M solution of the oxidized metal ions at pH = 7.

13.57 A total charge of 4.5 kC is passed through an electrolytic cell. Determine the quantity of substance produced in each case: (a) the mass (in grams) of bismuth metal from a bismuth nitrate solution; (b) the volume (in liters at 273 K and 1.00 atm) of hydrogen gas from a sulfuric acid solution; (c) the mass of cobalt (in grams) from a cobalt(III) chloride solution.

13.58 A total charge of 96.5 kC is passed through an electrolytic cell. Determine the quantity of substance produced in each case: (a) the mass (in grams) of silver metal from a silver nitrate solution; (b) the volume (in liters at 273 K and 1.00 atm) of chlorine gas from a brine solution (concentrated aqueous sodium chloride solution); (c) the mass of copper (in grams) from a copper(II) chloride solution.

13.59 (a) How much time is required to electroplate 1.50 g of silver from a silver nitrate solution by using a current of 13.6 mA? (b) When the same current is used for the same length of time, what mass of copper can be electroplated from a copper(II) sulfate solution?

13.60 (a) When a current of 324 mA is used for 7.0 h, what volume (measured in liters at 298 K and 1.0 atm) of fluorine gas can be produced from a molten mixture of potassium and hydrogen fluorides? (b) With the same current and time period, how many liters of oxygen gas at 298 K and 1.0 atm can be produced from the electrolysis of water?

13.61 (a) What current is required to produce 2.5 g of chromium metal from chromium(VI) oxide in 12 h? (b) What current is required to produce 2.5 g of sodium metal from molten sodium chloride in the same period?

13.62 What current is required to electroplate 6.66 μg of gold in 30.0 min from a gold(III) chloride aqueous solution? (b) How much time is required to electroplate 6.66 μg of chromium from a potassium dichromate solution, by using a current of 100 mA?

13.63 When a ruthenium chloride solution was electrolyzed for 500 s with a 120-mA current, 31.0 mg of ruthenium was deposited. What is the oxidation number of ruthenium in the ruthenium chloride?

13.64 A 4.9-g sample of manganese was produced from a manganese nitrate aqueous solution when a current of 350 mA was passed for 13.7 h. What is the oxidation number of manganese in the manganese nitrate?

13.65 A current of 15.0 A electroplated 50.0 g of hafnium metal from an aqueous solution in 2.00 h. What is the oxidation number of hafnium in the solution?

13.66 A mass loss of 12.57 g occurred in 6.00 h at a titanium anode when a current of 4.70 A was used in an electrolytic cell. What is the oxidation number of the titanium in solution?

13.67 Copper from a 200.0-mL solution of copper(II) sulfate is plated on to the cathode of an electrolytic cell. (a) Hydronium ions are generated at one of the electrodes. Is this electrode the anode or cathode? (b) How many moles of H_3O^+ are generated if a current of 0.120 A is applied to the cell for 30.0 h? (c) If the pH of the solution was initially 7.0, what will be the pH of the solution after the electrolysis? Assume no change in the volume of solution.

13.68 Thomas Edison was faced with the problem of measuring the electricity that each of his customers had used. His first solution was to use a zinc "coulometer," an electrolytic cell in which the quantity of electricity is determined by measuring the mass of zinc deposited. Only some of the current used by the customer passed through the coulometer. (a) What mass of zinc would be deposited in 1 month (of 31 days) if 1.0 mA of current passed through the cell continuously? (b) An alternative solution to this problem is to collect the hydrogen produced by electrolysis and measure its volume. What volume would be collected at 298 K and 1.00 bar under the same conditions? (c) Which method would be more practical?

Impact on Materials

13.69 The "aluminum–air fuel cell" is used as a reserve battery in remote locations. In this cell aluminum reacts with the oxygen in air in basic solution. (a) Write the oxidation and reduction half-reactions for this cell. (b) Calculate the standard cell potential. See Box 13.1.

13.70 A fuel cell in which hydrogen reacts with nitrogen instead of oxygen is proposed. (a) Write the chemical equation for the reaction in water, which produces aqueous ammonia. (b) What would be the maximum free energy output of the cell for the consumption of 28.0 kg nitrogen? (c) Is this type of fuel cell thermodynamically feasible? See Box 13.1.

13.71 The body functions as a kind of fuel cell that uses oxygen from the air to oxidize glucose:

$$C_6H_{12}O_6(aq) + 6\,O_2(g) \longrightarrow 6\,CO_2(g) + 6\,H_2O(l)$$

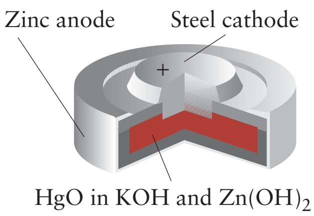
During normal activity, a person uses the equivalent of about 10 MJ of energy a day. Assume that this value represents ΔG, and estimate the average current through your body in the course of a day, assuming that all the energy that we use arises from the reduction of O_2 in the glucose oxidation reaction. See Box 13.1.

13.72 A photoelectrochemical cell is an electrochemical cell that uses light to carry out a chemical reaction. This type of cell is being considered for the production of hydrogen from water. The silicon electrodes in a photoelectrochemical cell react with water:

$$SiO_2(s) + 4\,H^+(aq) + 4\,e^- \longrightarrow Si(s) + 2\,H_2O(l) \qquad E^\circ = -0.84\text{ V}$$

Calculate the standard cell potential for the reaction between silicon and water in a cell that also produces hydrogen from water and write the balanced equation for the cell reaction. See Box 13.1.

13.73 What is (a) the electrolyte and (b) the oxidizing agent in the mercury cell shown here? (c) Write the overall cell reaction for a mercury cell.



13.74 What is (a) the electrolyte and (b) the oxidizing agent during discharge in a lead–acid battery? (c) Write the reaction that takes place at the cathode during the charging of the lead–acid battery.

13.75 (a) Write the cell reaction for the lead–acid battery. (b) Explain how each of the following change in a lead–acid battery during discharge: pH; amount of PbO_2; total amount of lead in the battery.

13.76 The density of the electrolyte in a lead–acid battery is measured to assess its state of charge. Explain how the density indicates the state of charge of the battery.

13.77 (a) What is the electrolyte in a nickel–cadmium cell? (b) Write the reaction that takes place at the anode when the cell is being charged. (See Table 13.2.)

13.78 (a) Why are lead–antimony grids used as electrodes in the lead–acid battery rather than smooth plates? (b) What is the reducing agent in the lead–acid battery? (c) The lead–acid cell potential is about 2 V. How, then, does a car battery produce 12 V for its electrical system?

13.79 A chromium-plated steel bicycle handlebar is scratched. Will rusting of the iron in the steel be encouraged or retarded by the chromium?

13.80 A solution is prepared by dissolving 1 mol each of $Cu(NO_3)_2$, $Ni(NO_3)_2$, and $AgNO_3$ in 1.0 L of water. Using only data from Appendix 2B, identify the metals (if any) that when added to these solutions (a) will leave the Ni^{2+} ions unaffected but will cause Cu and Ag to plate out of solution; (b) will leave the Ni^{2+} and Cu^{2+} ions in solution but will cause Ag to plate out of solution; (c) will leave all three metals ions in solution; (d) will leave Ni^{2+} and Ag^+ ions in solution but will cause Cu to plate out of solution.

13.81 Suppose that 2.69 g of a silver salt (AgX) is dissolved in 550 mL of water. With a current of 3.5 A, 395.0 s was needed to plate out all the silver. (a) What is the mass percentage of silver in the salt? (b) What is the formula of the salt?

13.82 Three electrolytic cells containing solutions of $CuNO_3$, $Sn(NO_3)_2$, and $Fe(NO_3)_3$, respectively, are connected in series. A current of 3.5 A is passed through the cells until 3.05 g of copper has been deposited in the first cell. (a) What masses of tin and iron are deposited? (b) For how long did the current flow?

13.83 (a) What is the approximate chemical formula of rust? (b) What is the oxidizing agent in the formation of rust? (c) How does the presence of salt accelerate the rusting process?

13.84 (a) What is the electrolyte solution in the formation of rust? (b) How are steel (iron) objects protected by galvanizing and by sacrificial anodes? (c) Suggest two metals that could be used in place of zinc for galvanizing iron.

13.85 (a) Suggest two metals that could be used for the cathodic protection of a titanium pipeline. (b) What factors other than relative positions in the electrochemical series need to be considered in practice? (c) Often copper piping is connected to iron pipes in household plumbing systems. What is a possible effect of the copper on the iron pipes?

13.86 (a) Can aluminum be used for the cathodic protection of a steel underground storage container? (b) Which of the metals zinc, silver, copper, and magnesium cannot be used as a sacrificial anode in the protection of a buried iron pipeline? Explain your answer. (c) What is the electrolyte solution for the cathodic protection of an underground pipeline by a sacrificial anode?

Integrated Exercises

13.87 Indicate for each of the following statements whether it applies to $E_{cell}°$, to E_{cell}, to both, or to neither. (a) Decreases as the cell reaction progresses. (b) Changes with temperature. (c) Doubles when the coefficients of the equation are doubled. (d) Can be calculated from K. (e) Is a measure of how far the cell reaction is from equilibrium. Justify your answers.

13.88 State how the oxidizing strength of each of the following oxidizing agents would be affected by raising the pH (stronger, weaker, or no change): (a) Br_2; (b) MnO_4^-; (c) NO_3^-; (d) ClO_4^-; (e) Cu^{2+}. Justify your answers.

13.89 Volta discovered that when he used different metals in his "pile" some combinations had a stronger effect than others. From that information he constructed an electromotive series. How would Volta have ordered the following metals, if he put the most strongly reducing metal first: Fe, Ag, Au, Zn, Cu, Ni, Co, Al?

13.90 Arrange the following metals in order of increasing strength as reducing agents: U, V, Ti, Ni, Sn, Cr, Rb.

13.91 A galvanic cell has the following cell reaction: $M(s) + 2\,Zn^{2+}(aq) \longrightarrow 2\,Zn(s) + M^{4+}(aq)$. The standard potential of the cell is +0.16 V. What is the standard potential of the M^{4+}/M redox couple?

13.92 Using data in Appendix 2B, calculate the standard potential for the half-reaction $Ti^{4+}(aq) + 4\,e^- \longrightarrow Ti(s)$.

13.93 K_{sp} for $Cu(IO_3)_2$ is 1.4×10^{-7}. Using this value and data available in Appendix 2B, calculate $E°$ for the half-reaction $Cu(IO_3)_2(s) + 2\,e^- \longrightarrow Cu(s) + 2\,IO_3^-(aq)$.

13.94 K_{sp} for $Ni(OH)_2$ is 6.5×10^{-18}. Using this value and data from Appendix 2B, calculate $E°$ for the half-reaction $Ni(OH)_2(s) + 2\,e^- \longrightarrow Ni(s) + 2\,OH^-(aq)$.

13.95 A voltaic cell functions only when the electrical circuit is complete. In the external circuit the current is carried by the flow of electrons through a metal wire. Explain how the current is carried through the cell itself.

13.96 A technical handbook contains tables of thermodynamic quantities for common reactions. If you want to know whether a certain cell reaction has a positive standard potential, which of the following properties would give you that information directly (on inspection)? Which would not? Explain your answer. (a) $\Delta G°$; (b) $\Delta H°$; (c) $\Delta S°$; (d) $\Delta U°$; (e) K.

13.97 Answer the following questions and, for each "yes" response, write a balanced cell reaction and calculate the standard cell potential. (a) Can the oxygen present in air oxidize silver metal in acidic solution under standard conditions? (b) Can the oxygen in air oxidize silver metal in basic solution under standard conditions?

13.98 One stage in the extraction of gold from rocks involves dissolving the metal from the rock with a basic solution of sodium cyanide that has been thoroughly aerated. This stage results in the formation of soluble $Au(CN)_2^-$ ions. The next stage is to reduce gold to the metal by the addition of zinc dust, forming $Zn(CN)_4^{2-}$. Write the balanced equations for the half-reactions and the overall redox equation for both stages.

13.99 (a) If you were to construct a concentration cell in which one half-cell contains 1.0 M $CrCl_3$ and the other half-cell 0.0010 M $CrCl_3$, and both electrodes were chromium, at which electrode would reduction spontaneously take place? How will each of the following changes affect the cell potential? Justify your answers. (b) Adding 100 mL pure water to the anode compartment. (c) Adding 100 mL 1.0 M NaOH(aq) to the cathode compartment ($Cr(OH)_3$ is insoluble). (d) Increasing the mass of the chromium electrode in the anode compartment.

13.100 Dental amalgam, a solid solution of silver and tin in mercury, is used for filling tooth cavities. Two of the reduction half-reactions that the filling can undergo are

$$3\,Hg_2^{2+}(aq) + 4\,Ag(s) + 6\,e^- \longrightarrow 2\,Ag_2Hg_3(s) \qquad E° = +0.85\text{ V}$$

$$Sn^{2+}(aq) + 3\,Ag(s) + 2\,e^- \longrightarrow Ag_3Sn(s) \qquad E° = -0.05\text{ V}$$

Suggest a reason why, when you accidentally bite on a piece of aluminum foil with a tooth containing a silver filling, you may feel

pain. Write a balanced chemical equation to support your suggestion.

13.101 Suppose that 25.0 mL of a solution of Ag^+ ions of unknown concentration is titrated with 0.015 M KI(aq) at 25°C. A silver electrode is immersed in this solution, and its potential is measured relative to a standard hydrogen electrode. A total of 16.7 mL of KI(aq) was required to reach the stoichiometric point, when the potential was 0.325 V. (a) What is the molar concentration of Ag^+ in the solution? (b) Determine K_{sp} for AgI from these data.

13.102 Suppose that 35.0 mL of 0.012 M Cu^+(aq) is titrated with 0.010 M KBr(aq) at 25°C. A copper electrode is immersed in this solution, and its potential is measured relative to a standard hydrogen electrode. What volume of the KBr solution must be added to reach the stoichiometric point and what will the potential be at that point? $K_{sp}(\text{CuBr}) = 5.2 \times 10^{-9}$.

13.103 Use the data in Appendix 2B and the fact that, for the half-reaction $F_2(g) + 2\,H^+(aq) + 2\,e^- \longrightarrow 2\,HF(aq)$, $E° = +3.03$ V, to calculate the value of K_a for HF.

13.104 The following items are obtained from the stockroom for the construction of a galvanic cell: two 250-mL beakers and a salt bridge, a voltmeter with attached wires and clips, 200 mL of 0.0080 M $CrCl_3$(aq), 200 mL of 0.12 M $CuSO_4$(aq), a piece of copper wire, and a chrome-plated piece of metal. (a) Describe the construction of the galvanic cell. (b) Write the reduction half-reactions. (c) Write the overall cell reaction. (d) Write the cell diagram for the galvanic cell. (e) What is the expected cell potential?

13.105 (a) Considering the dependence of the Gibbs free energy of reaction on potential and on temperature, derive an equation for the temperature dependence of $E_{cell}°$. (b) Use your equation to predict the standard potential for the formation of water from hydrogen and oxygen in a fuel cell at 80°C. Assume that $\Delta H°$ and $\Delta S°$ are independent of temperature.

13.106 (a) What is the standard cell potential ($E_{cell}°$) for the reaction below at 298 K? (b) What is the standard cell potential for the reaction at 335 K? (c) What is the cell potential for the reaction at 335 K when $[Zn^{2+}] = 2.0 \times 10^{-4}$ mol·L^{-1} and $[Pb^{2+}] =$ 1.0 mol·L^{-1}? (See Exercise 13.105.)

$$Pb^{2+}(aq) + Zn(s) \longrightarrow Zn^{2+}(aq) + Pb(s)$$

13.107 In a neuron (a nerve cell), the concentration of K^+ ions inside the cell is about 20 to 30 times as great as that outside. What potential difference between the inside and the outside of the cell would you expect to measure if the difference is due only to the imbalance of potassium ions?

13.108 (a) The potential of the cell $Zn(s)|Zn^{2+}(aq, ?)||Pb^{2+}(aq, 0.10\ mol \cdot L^{-1})|Pb(s)$ is +0.661 V. What is the molarity of Zn^{2+} ions? (b) Write an equation that gives the Zn^{2+} ion concentration as a function of cell potential, assuming that all other aspects of the cell remain constant.

13.109 (a) Using data available in Appendix 2B, determine the standard potential for the redox reaction $2\,Ag^+(aq) + 2\,I^-(aq) \longrightarrow 2\,Ag(s) + I_2(s)$. Is this process spontaneous under standard conditions? (b) When equal volumes of 2.0 M $AgNO_3$(aq) and 2.0 M NaI(aq) are mixed, the redox reaction described in part (a) does not take place. Instead, a precipitate of AgI is formed. Why doesn't the redox reaction take place? Support your answer with an appropriate calculation.

13.110 What is the standard potential for the reduction of oxygen to water in (a) an acidic solution? (b) a basic solution? (c) Is MnO_4^- more stable in an acidic or a basic aerated solution (a solution saturated with oxygen gas at 1 atm)? Explain your conclusion.

13.111 When a pH meter was standardized with a boric acid–borate buffer with a pH of 9.40, the cell was +0.060 V. When the buffer was replaced with a solution of unknown hydronium ion concentration, the cell potential was +0.22 V. What is the pH of the solution?

13.112 Show how a silver–silver chloride electrode (silver in contact with solid AgCl and a solution of Cl^- ions) and a hydrogen electrode can be used to measure (a) pH; (b) pOH.

13.113 What range (in volts) does a voltmeter need to have in order to measure pH in the range of 1 to 14 at 25°C if the voltage is zero when pH = 7?

13.114 The entropy change of a cell reaction can be determined from the change of the cell potential with temperature. (a) Show that $\Delta S° = nF(E_{cell,2}° - E_{cell,1}°)/(T_2 - T_1)$. Assume that $\Delta S°$ and $\Delta H°$ are constant over the temperature range considered. (b) Calculate $\Delta S°$ and $\Delta H°$ for the cell reaction $Hg_2Cl_2(s) + H_2(g) \longrightarrow 2\,Hg(l) + 2\,H^+(aq) + 2\,Cl^-(aq)$, given that $E° = +0.2699$ V at 293 K and +0.2669 V at 303 K.

13.115 A silver concentration cell is constructed with the electrolyte at both electrodes being initially 0.10 M AgNO(aq) at 25°C. The electrolyte at one electrode is diluted by a factor of 10 five times and the cell potential measured each time. (a) Plot the potential of this cell on a graph as a function of $\ln[Ag^+]_{anode}$. (b) Calculate the value of the slope of the line. To what term in the Nernst equation does this value correspond? Is the value you determined from the plot consistent with the value you would calculate from the values in that term? If not consistent, calculate your percentage error. (c) What is the value of the *y*-intercept? To what term in the Nernst equation does this value correspond?

13.116 Consider the electroplating of a metal +1 cation from a solution of unknown concentration according to the half-reaction $M^+(aq) + e^- \longrightarrow M(s)$, with a standard potential $E°$. When the half-cell is connected to an appropriate oxidation half-cell and current is passed through it, the M^+ cation begins plating out at E_1. To what value (E_2) must the applied potential be adjusted, relative to E_1, if 99.99% of the metal is to be removed from the solution?

13.117 Using only data given in Appendix 2B, calculate the acidity constant for HBrO.

13.118 The absolute magnitudes of the standard potentials of two metals M and X were determined to be

(1) $M^+(aq) + e^- \longrightarrow M(s) \qquad |E°| = 0.25$ V

(2) $X^{2+}(aq) + 2\,e^- \longrightarrow X(s) \qquad |E°| = 0.65$ V

When the two electrodes are connected, current flows from M to X in the external circuit. When the electrode corresponding to half-reaction 1 is connected to the standard hydrogen electrode (SHE), current flows from M to SHE. (a) What are the signs of $E°$ of the two half-reactions? (b) What is the standard cell potential for the cell constructed from these two electrodes?

13.119 An aqueous solution of Na_2SO_4 was electrolyzed for 30.0 min; 25.0 mL of oxygen was collected at the anode over water at 22°C and a total pressure of 722 Torr. Determine the current

that was used to produce the gas. See Table 9.3 for the vapor pressure of water.

13.120 A brine solution is electrolyzed by using a current of 2.0 A. How much time is required to collect 20.0 L of chlorine if the gas is collected over water at 20.0°C and the total pressure is 770. Torr? Assume that the water is already saturated with chlorine, and so no more dissolves. See Table 9.3 for the vapor pressure of water.

Chemistry Connections

13.121 Many important biological reactions involve electron transfer. Because the pH of bodily fluids is close to 7, the "biological standard potential" of an electrode, E^*, is measured at pH = 7.

(a) Calculate the biological standard potential for (i) the reduction of hydrogen ions to hydrogen gas; (ii) the reduction of nitrate ions to NO gas.

(b) Calculate the biological standard potential E^* for the reduction of the biomolecule NAD^+ to NADH in aqueous solution. The reduction half-reaction under thermodynamic standard conditions is $NAD^+(aq) + H^+(aq) + 2\,e^- \longrightarrow NADH(aq)$, with $E° = -0.099$ V.

(c) The pyruvate ion, $CH_3C({=}O)CO_2^-$, is formed during the metabolism of glucose in the body. The ion has a chain of three carbon atoms. The central carbon atom has a double bond to a terminal oxygen atom and one of the end carbon atoms is bonded to two oxygen atoms in a carboxylate group. Draw the Lewis structure of the pyruvate ion and assign a hybridization scheme to each carbon atom.

(d) The lactate ion has a similar structure to the pyruvate ion, except that the central carbon is now attached to an –OH group: $CH_3CH(OH)CO_2^-$. Draw the Lewis structure of the lactate ion and assign a hybridization scheme to the central carbon atom.

(e) During exercise the pyruvate ion is converted to lactate ion in the body by coupling to the half reaction for NADH given in part (b). For the half-reaction pyruvate $+ 2\,H^+ + 2\,e^- \longrightarrow$ lactate, $E^* = -0.190$ V. Write the cell reaction for the spontaneous reaction that occurs between these two biological couples and calculate E^* and $E°$ for the overall reaction.

(f) Calculate the standard Gibbs free energy of reaction for the overall reaction in part (e).

(g) Calculate the equilibrium constant at 25°C for the overall reaction in part (e).

What Are the Key Ideas? The rates of chemical reactions can be described by simple expressions that enable us to predict the composition of a reaction mixture at any time; these expressions also suggest the steps by which the reaction takes place.

Why Do We Need to Know This Material? Chemical kinetics provides us with tools that we can use to study the rates of chemical reactions on both the macroscopic and the atomic levels. At the atomic level, chemical kinetics is a source of insight into the nature and mechanisms of chemical reactions. At the macroscopic level, information from chemical kinetics allows us to model complex systems, such as the processes taking place in the human body and the atmosphere. The development of catalysts, which are substances that speed up chemical reactions, is a branch of chemical kinetics crucial to the chemical industry, to the solution of major problems such as world hunger, and to the development of new fuels.

What Do We Need to Know Already? It might be helpful to review the kinetic model of gases (Section 4.10) and equilibrium constants (Section 10.2).

In the previous four chapters we used thermodynamics to predict the spontaneous direction and extent of chemical change. However, thermodynamics does not tell us how fast the reaction goes. Some spontaneous reactions—such as the decomposition of benzene into carbon and hydrogen—do not seem to proceed at all, whereas other reactions—such as proton transfer reactions—reach equilibrium very rapidly. In this chapter, we examine the intimate details of how reactions proceed, what determines their rates, and how to control those rates. The study of the rates of chemical reactions is called **chemical kinetics.** When studying thermodynamics, we consider only the initial and final states of a chemical process (its origin and destination) and ignore what happens between them (the journey itself, with all its obstacles). In chemical kinetics, we focus on the journey—the changes that take place in the course of reactions and the speed of each step.

This chapter begins by looking at how the rates of reactions are determined experimentally and summarized by succinct expressions known as *rate laws*. We then see how to use rate laws to predict the concentrations of reactants and products at any stage of a reaction and to gain insight about how reactions occur. Finally, we see how substances called catalysts accelerate reactions and control biological processes.

REACTION RATES

What do we mean by the "rate" of a chemical reaction? Informally, we consider a reaction to be fast if the products are formed rapidly, as occurs in a precipitation reaction or an explosion (Fig. 14.1). A reaction is slow if the products are formed over a long period of time, as happens in corrosion or the decay of organic material (Fig. 14.2). Our first task is to set up a quantitative definition of the rate of a chemical reaction.

14.1 Concentration and Reaction Rate

In everyday life, a rate is defined as the change in a property divided by the time that it takes for that change to take place. For instance, the speed of an automobile, the rate of change of its position, is defined as distance traveled divided by the time taken. We get the *average speed* if we divide the length of the journey by the total time for the journey; we get the *instantaneous speed* by reading the speedometer at some point on the journey. In chemistry, we express rates in terms of how quickly reactants are used up or products are formed. That is, we define the **reaction rate** as the change in concentration of one of

FIGURE 14.1 Reactions proceed at widely different rates. Some, such as explosions of dynamite, are very fast. Charges have been set off to demolish this old building. The chemical reaction in each explosion is over in a fraction of a second; the gases produced expand more slowly.

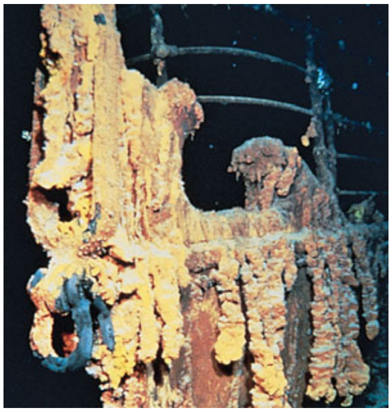

FIGURE 14.2 Some reactions are very slow, as in the gradual buildup of corrosion on the prow of the Titanic on the cold floor of the Atlantic Ocean.

the reactants or products divided by the time interval over which the change takes place. Because the rate may change as time passes, we denote the **average reaction rate** as the change in molar concentration of a reactant R, $\Delta[\mathrm{R}] = [\mathrm{R}]_{t_2} - [\mathrm{R}]_{t_1}$, divided by the time interval $\Delta t = t_2 - t_1$:

$$\text{Average rate of consumption of R} = -\frac{\Delta[\mathrm{R}]}{\Delta t} \qquad \mathbf{(1a)}^*$$

Because reactants are used up in a reaction, the concentration of R decreases as time passes; thus, $\Delta[\mathrm{R}]$ is negative. The minus sign in Eq. 1a is included to ensure that the rate is positive, which is the normal convention in chemical kinetics. If we follow the concentration of a product P, we express the rate as

$$\text{Average rate of formation of P} = \frac{\Delta[\mathrm{P}]}{\Delta t} \qquad \mathbf{(1b)}^*$$

In this expression, $\Delta[\mathrm{P}]$ is the change in molar concentration of P during the interval Δt: it is a positive quantity because products are formed as time goes on.

A note on good practice: In chemical kinetics, the square brackets denote molar concentration, with the units $\mathrm{mol{\cdot}L^{-1}}$ retained.

EXAMPLE 14.1 Calculating an average reaction rate

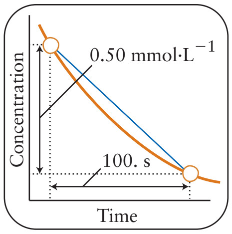
Suppose we are studying the reaction $2\,\mathrm{HI(g)} \longrightarrow \mathrm{H_2(g)} + \mathrm{I_2(g)}$ and find that, in an interval of 100. s, the concentration of HI decreases from 4.00 $\mathrm{mmol{\cdot}L^{-1}}$ to 3.50 $\mathrm{mmol{\cdot}L^{-1}}$. What is the average reaction rate?

PLAN Substitute the data into Eq. 1a.

SOLVE

From Average rate of consumption of R $= -\Delta[\mathrm{R}]/\Delta t$,

$$\begin{aligned}\text{Average rate of consumption of HI} &= -\frac{(3.50 - 4.00)(\mathrm{mmol\ HI}){\cdot}\mathrm{L^{-1}}}{100.\ \mathrm{s}} \\ &= 5.0 \times 10^{-3}\ (\mathrm{mmol\ HI}){\cdot}\mathrm{L^{-1}{\cdot}s^{-1}}\end{aligned}$$



In the plot, the slope of the straight blue line gives the average rate.

A note on good practice: It is best to choose multiples of units that minimize the powers of 10 shown explicitly. In this case, because 10^{-3} mmol = 1 μmol, it would be good practice to report the rate as 5.0 (μmol HI)$\cdot\mathrm{L^{-1}{\cdot}s^{-1}}$.

Self-Test 14.1A When the reaction $2\,HI(g) \longrightarrow H_2(g) + I_2(g)$ was carried out at a high temperature, the concentration of HI decreased from 6.00 $mmol{\cdot}L^{-1}$ to 4.20 $mmol{\cdot}L^{-1}$ in 200. s. What was the average reaction rate?

[***Answer:*** 9.00 (μmol HI)$\cdot L^{-1}\cdot s^{-1}$]

Self-Test 14.1B Hemoglobin (Hb) carries oxygen through our bodies by forming a complex with it: $Hb(aq) + O_2(aq) \longrightarrow HbO_2(aq)$. In a solution of hemoglobin exposed to oxygen, the concentration of hemoglobin fell from 1.2 $nmol{\cdot}L^{-1}$ (1 nmol = 10^{-9} mol) to 0.80 $nmol{\cdot}L^{-1}$ in 0.10 μs. What was the average rate at which hemoglobin reacted with oxygen in that solution, in millimoles per liter per microsecond?

In Example 14.1, the reaction rate was reported in the units micromoles per liter per second ($\mu mol{\cdot}L^{-1}{\cdot}s^{-1}$), but other units for time (such as minutes or even hours) are commonly encountered for slower reactions. Note, too, that, when we report a reaction rate, we must specify the species to which the rate refers, because species are consumed or produced at rates related to the stoichiometry of the reaction. For example, in the reaction in Example 14.1, two HI molecules are used to make one H_2 molecule. Therefore, the rate of consumption of HI is twice the rate of formation of H_2 and we conclude that

$$-\frac{\Delta[H_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[HI]}{\Delta t}$$

To avoid the ambiguity associated with several ways of reporting a reaction rate, we can report a single unique average rate of a reaction without specifying the species. The **unique average rate** of the reaction $a\,A + b\,B \longrightarrow c\,C + d\,D$ is any of the following four equal quantities:

$$\text{Unique average reaction rate} = -\frac{1}{a}\frac{\Delta[A]}{\Delta t} = -\frac{1}{b}\frac{\Delta[B]}{\Delta t} = \frac{1}{c}\frac{\Delta[C]}{\Delta t} = \frac{1}{d}\frac{\Delta[D]}{\Delta t} \qquad (2)^*$$

Division by the stoichiometric coefficients takes care of the stoichiometric relations between the reactants and products. There is no need to specify the species when reporting the unique average reaction rate, because the value of the rate is the same, regardless of which species is indicated. However, the unique average rate does depend on the coefficients used in the balanced equation, and so the chemical equation should be specified when reporting the unique rate.

Thinking point: By what factor does the unique average reaction rate change if the coefficients in a chemical equation are doubled?

Self-Test 14.2A The average rate of the reaction $N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g)$ over a certain period is reported as 1.15 (mmol NH_3)$\cdot L^{-1}\cdot h^{-1}$. (a) What is the average rate over the same period in terms of the consumption of H_2? (b) What is the unique average rate?

[***Answer:*** (a) 1.72 (mmol H_2)$\cdot L^{-1}\cdot h^{-1}$;
(b) 0.575 $mmol{\cdot}L^{-1}{\cdot}h^{-1}$]

Self-Test 14.2B Consider the reaction in Example 14.1. What is (a) the average rate of formation of H_2 in the same reaction and (b) the unique average rate, both over the same period?

The experimental technique that we employ to measure a rate of reaction depends on how rapidly the reaction takes place. Some biologically important reactions, such as the growth of hair, may take weeks to show significant changes, but other reactions, such as the explosion of nitroglycerin, are very rapid. Special techniques have to be used when the reaction is so fast that it is over in seconds. There are two main considerations. One is to initiate the reaction at a very precise time. The other is to monitor the concentration at precise instants after the reaction has been initiated.

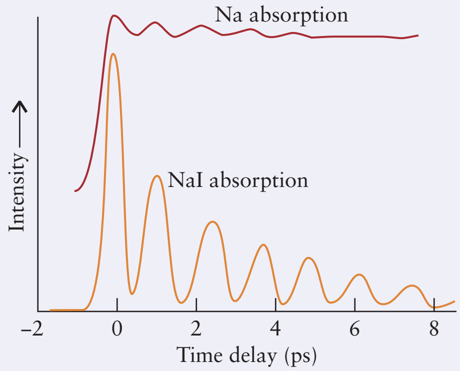
Some reactions can be initiated by a flash of light. Because lasers can produce very short pulses at precisely known times they are often used to study the rates of such

BOX 14.1 HOW DO WE KNOW . . . WHAT HAPPENS TO ATOMS DURING A REACTION?

The events that happen to an atom in a chemical reaction are on a time scale of approximately 1 femtosecond (1 fs = 10^{-15} s), the time that it takes for a bond to stretch or bend and, perhaps, break. If we could follow atoms on that time scale, we could make a movie of the changes in molecules as they take part in a chemical reaction. The new field of *femtochemistry*, the study of very fast chemical processes, is bringing us closer to realizing that dream. Lasers can emit very intense but short pulses of electromagnetic radiation, and so they can be used to study processes on very short time scales.

So far, the technique has been applied only to very simple reactions. For example, it is possible to watch the ion pair Na^+I^- decompose in the gas phase into separate Na and I atoms. At the start, the sodium ion and iodide ion are held together by the coulombic attraction of opposite charges. The pair is then struck by a femtosecond pulse of radiation from a laser. That pulse excites an electron from the I^- ion on to the Na^+ ion, thereby creating an NaI molecule in which the two atoms are held together by a covalent bond. The molecule has a lot of energy, and the bond length varies as the atoms swing in and out. At this point, a second femtosecond pulse is fired at the molecule. The radiation in the second pulse has a frequency that can be absorbed by the molecule only when the atoms have a particular separation. If the pulse is absorbed, we know that the atoms of the vibrating molecule have that special internuclear separation.

The illustration shows a typical result. The absorption reaches a maximum whenever the Na–I bond length returns to the length to which the second pulse is tuned. The peaks show that the sodium atom moves away from the iodine atom (corresponding to the dips in the curve), only to be recaptured (at the maxima) again. The separation of the maxima is about 1.3 ps, and so the Na atom takes that long to swing out and be recaptured by the I atom. We can see that the peaks progressively decrease in intensity, showing that some Na atoms escape from their I atom partners on each swing. It takes about 10 swings outward before an Na atom can be sure of escaping. When sodium bromide is studied by these methods, the sodium atom escapes after about one swing, showing that an Na atom can escape more readily from a Br atom than from an I atom.



The femtosecond spectrum of the gas-phase NaI molecule as it dissociates into the separate atoms. A peak in the lower spectrum is observed whenever the bond distance in NaI reaches a certain value.

reactions. Spectrometry—the determination of concentrations by measuring the absorption of light by species (see Major Technique 2, following Chapter 3)—can respond very quickly to concentration changes and is often used in combination with a laser flash to study very fast reactions. For instance, suppose we are studying the effect of a chlorofluorocarbon on the concentration of ozone, a blue gas that absorbs light of certain wavelengths. We could use a spectrometer to monitor the light absorbed by the ozone at one of those wavelengths and calculate the molar concentration of O_3 molecules from the intensity of absorption. By using pulsed lasers chemists can study reactions that are complete in less than a picosecond (1 ps = 10^{-12} s). The newest techniques can even monitor reactions that are complete after a few femtoseconds (1 fs = 10^{-15} s, Box 14.1) and chemists are now investigating processes even on an attosecond timescale (1 as = 10^{-18} s). On that time scale, atoms seem hardly to be moving and are caught red-handed in the act of reaction.

Reactions that are initiated by mixing the reagents can be studied by the **stopped-flow technique,** in which solutions of the reactants are forced into a mixing chamber very rapidly and within a few milliseconds the formation of products is observed spectroscopically (Fig. 14.3). This procedure is commonly used to study biologically important reactions.

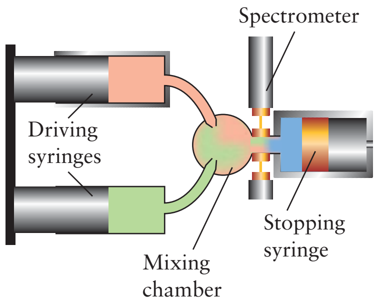


FIGURE 14.3 In a stopped-flow experiment, the driving syringes on the left push reactant solutions into the mixing chamber, and the stopping syringe on the right stops the flow. The progress of the reaction is then monitored spectroscopically as a function of time.

The average rate of a reaction is the change in concentration of a species divided by the time over which the change takes place; the unique average rate is the average rate divided by the stoichiometric coefficient of the species monitored. Spectroscopic techniques are widely used to study reaction rates, particularly for fast reactions.

14.2 The Instantaneous Rate of Reaction

Most reactions slow down as the reactants are used up. To determine the reaction rate at a given instant in the course of the reaction, we need to make two concentration measurements as close together in time as possible. In other words, to determine the rate at a single instant we determine the slope of the *tangent* to the plot of concentration against time at the time of interest (Fig. 14.4). This slope, which changes in the course of the reaction, is called the **instantaneous rate** of the reaction (Fig. 14.5).

From now on, whenever we speak of a reaction rate, we shall always mean an instantaneous rate. The definitions in Eqs.1 and 2 can easily be adapted to refer to the instantaneous rate of a reaction.

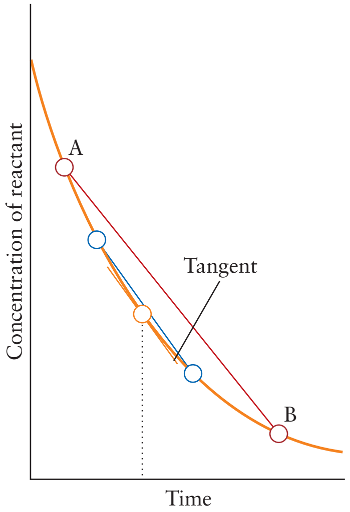

FIGURE 14.4 The rate of reaction is the change in concentration of a reactant (or product) divided by the time interval over which the change occurs (the slope of the line AB, for instance). The *instantaneous* rate is the slope of the tangent to the curve at the time of interest.

HOW DO WE DO THAT?

To set up expressions for the instantaneous rate of a reaction, we consider the time interval Δt to be so brief that t and $t + \Delta t$ are very close together; we determine the concentration of a reactant or product at each of those times and find the average rate from Eq. 1. Then we decrease the interval still further and repeat the calculation. We can imagine continuing the process until the interval Δt has become infinitely small (denoted dt) and the change in molar concentration of a reactant R has become infinitesimal (denoted d[R]). Then we define the instantaneous rate as

$$\text{Rate of consumption of R} = -\frac{d[R]}{dt}$$

For a product P, we write

$$\text{Rate of formation of P} = \frac{d[P]}{dt}$$

The terms d[R]/dt and d[P]/dt are the mathematical expressions for the slope of the tangent drawn to a curve at the time of interest. Similarly, the unique instantaneous rate of a reaction is defined as in Eq. 2, but with differential coefficients in place of $\Delta[R]/\Delta t$ and $\Delta[P]/\Delta t$:

$$\text{Reaction rate} = -\frac{1}{a}\frac{d[A]}{dt} = -\frac{1}{b}\frac{d[B]}{dt} = \frac{1}{c}\frac{d[C]}{dt} = \frac{1}{d}\frac{d[D]}{dt}$$

Because it is difficult to draw a tangent accurately by eye, it is better to use a computer to analyze graphs of concentration against time. A superior method—which we meet in Section 14.4—is to report rates by using a procedure that, although based on these definitions, avoids the use of tangents altogether.

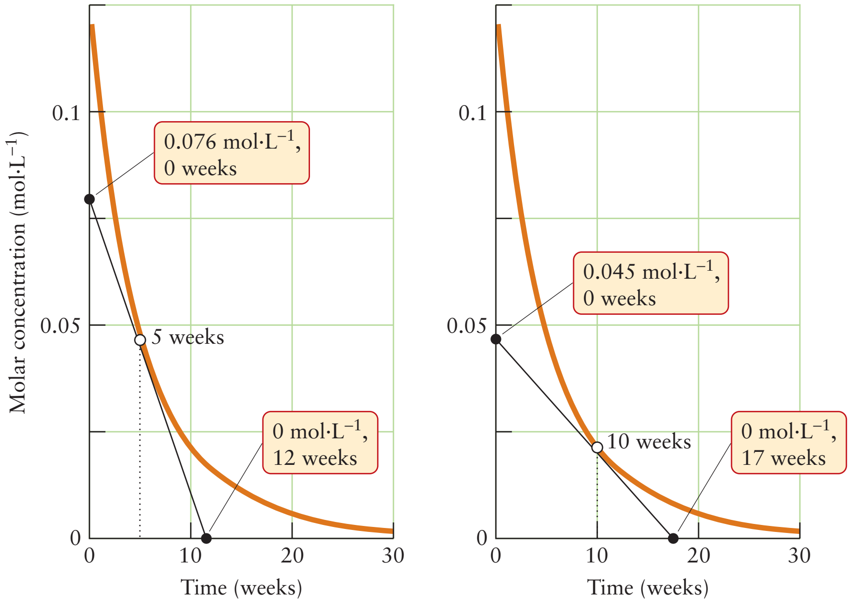

FIGURE 14.5 Determination of the rate of deterioration of penicillin during storage at two different times. Note that the rate (the slope of the tangent to the curve) at 5 weeks is greater than the rate at 10 weeks, when less penicillin is present.

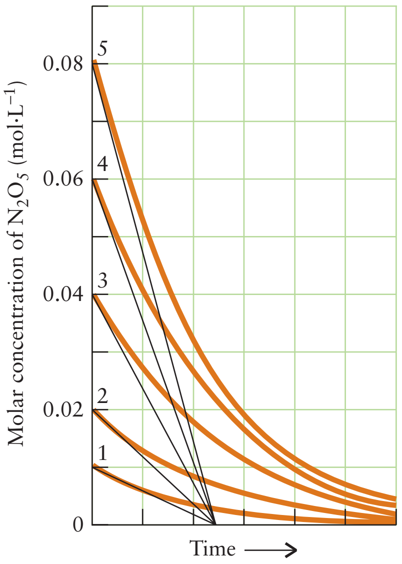

FIGURE 14.6 The orange curves show how the concentration of N_2O_5 changes with time for five different initial concentrations. The initial rate of consumption of N_2O_5 can be determined by drawing a tangent (black line) to each curve at the start of the reaction.

The instantaneous reaction rate is the slope of a tangent drawn to the graph of concentration as a function of time; for most reactions the instantaneous rate changes as the reaction proceeds.

14.3 Rate Laws and Reaction Order

Patterns in reaction rate data can often be identified by examining the **initial rate** of reaction, the instantaneous rate right at the start of a reaction (Fig. 14.6). The advantage of examining the initial rate is that the presence of products later in the reaction may affect the rate; the interpretation of the rate is then quite complicated. There are no products present at the start of the reaction, and so any pattern due solely to the reactants themselves is easier to find.

For example, suppose we were to measure different amounts of solid dinitrogen pentoxide, N_2O_5, into five flasks of the same volume, immerse all the flasks in a water bath at 65°C to vaporize the solid completely, and then use spectrometry to monitor the concentration of N_2O_5 remaining in each flask as it decomposes:

$$2\,N_2O_5(g) \longrightarrow 4\,NO_2(g) + O_2(g) \qquad \textbf{(A)}$$

Each flask has a different initial concentration of N_2O_5. We determine the initial rate of reaction in each flask by plotting the concentration as a function of time for each flask and drawing the tangent to each curve at $t = 0$ (the black lines in Fig. 14.6). We find higher initial rates of decomposition of the vapor—steeper tangents—in the flasks with higher initial concentrations of N_2O_5. Is there a pattern in the data? One way to find out is to plot the initial rate against concentration and examine the type of curve obtained. In this case, by plotting the initial rate against the initial concentration of N_2O_5 we get a straight line, which tells us that the initial rate is proportional to the initial concentration (Fig. 14.7):

$$\text{Initial rate of consumption of } N_2O_5 \propto [N_2O_5]_{\text{initial}}$$

If we introduce a constant k, we can write this proportionality as an equality:

$$\text{Initial rate of consumption of } N_2O_5 = k \times [N_2O_5]_{\text{initial}}$$

The constant k is called the **rate constant** for the reaction and is characteristic of the reaction (different reactions have different rate constants) and the temperature at which

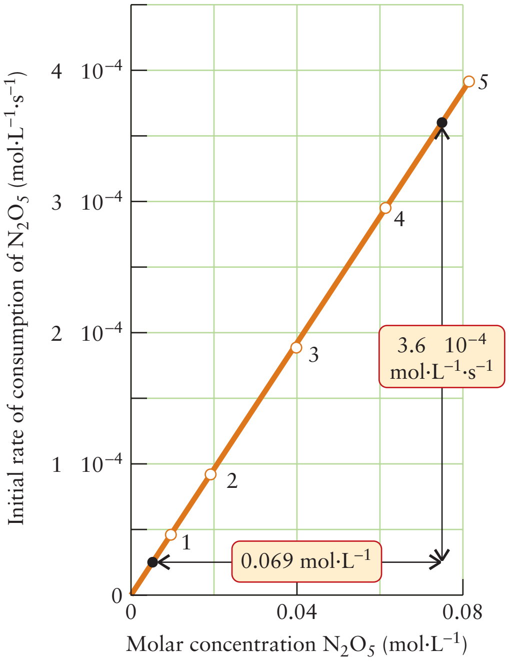

FIGURE 14.7 This graph was obtained by plotting the five initial rates from Fig. 14.6 against the initial concentration of N_2O_5. The initial rate is directly proportional to the initial concentration. This graph also illustrates how we can determine the value of the rate constant k by calculating the slope of the straight line from two points.

TABLE 14.1 Rate Laws and Rate Constants

Reaction	Rate law*	Temperature (K)†	Rate constant
Gas phase			
$H_2 + I_2 \longrightarrow 2\,HI$	$k[H_2][I_2]$	500	$4.3 \times 10^{-7}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$
		600	4.4×10^{-4}
		700	6.3×10^{-2}
		800	2.6
$2\,HI \longrightarrow H_2 + I_2$	$k[HI]^2$	500	$6.4 \times 10^{-9}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$
		600	9.7×10^{-6}
		700	1.8×10^{-3}
		800	9.7×10^{-2}
$2\,N_2O_5 \longrightarrow 4\,NO_2 + O_2$	$k[N_2O_5]$	298	$3.7 \times 10^{-5}\ s^{-1}$
		318	5.1×10^{-4}
		328	1.7×10^{-3}
		338	5.2×10^{-3}
$2\,N_2O \longrightarrow 2\,N_2 + O_2$	$k[N_2O]$	1000	$0.76\ s^{-1}$
		1050	3.4
$2\,NO_2 \longrightarrow 2\,NO + O_2$	$k[NO_2]^2$	573	$0.54\ L{\cdot}mol^{-1}{\cdot}s^{-1}$
$C_2H_6 \longrightarrow 2\,CH_3$	$k[C_2H_6]$	973	$5.5 \times 10^{-4}\ s^{-1}$
cyclopropane $\longrightarrow$ propene	k[cyclopropane]	773	$6.7 \times 10^{-4}\ s^{-1}$
Aqueous solution			
$H_3O^+ + OH^- \longrightarrow 2\,H_2O$	$k[H^+][OH^-]$	298	$1.5 \times 10^{11}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$
$CH_3Br + OH^- \longrightarrow CH_3OH + Br^-$	$k[CH_3Br][OH^-]$	298	$2.8 \times 10^{-4}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$
$C_{12}H_{22}O_{11} + H_2O \longrightarrow 2\,C_6H_{12}O_6$	$k[C_{12}H_{22}O_{11}][H^+]$	298	$1.8 \times 10^{-4}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$

*For the unique instantaneous rate.
†Three significant figures.

the reaction takes place. The experimental value of k for this reaction at 65°C, the slope of the straight line in Fig. 14.7, is $5.2 \times 10^{-3}\ s^{-1}$.

We have found that the initial rate of reaction A is proportional to the initial concentration of N_2O_5. If we were to follow the reaction rate in one of the flasks as the reaction proceeds we would also find that as the concentration of N_2O_5 falls, the rate falls too. More specifically, we would find that the rate at any instant is directly proportional to the concentration of N_2O_5 remaining at that instant, with the same constant of proportionality, k. We therefore conclude that, at *any* stage of the reaction, and provided products do not participate in the reaction,

$$\text{Rate of consumption of } N_2O_5 = k[N_2O_5]$$

where $[N_2O_5]$ is the molar concentration of N_2O_5 at any instant. This equation is an example of a **rate law,** an expression for the instantaneous reaction rate in terms of the concentration of a species at any instant. Each reaction has its own characteristic rate law and rate constant k that is independent of the concentrations of the reactants (Table 14.1).

Other reactions have rate laws that may depend differently on concentration. When we make similar measurements on the reaction

$$2\,NO_2(g) \longrightarrow 2\,NO(g) + O_2(g) \qquad \textbf{(B)}$$

we do not get a straight line if we plot rate against concentration of NO_2 (Fig. 14.8a). However, if we plot the rate against the *square* of the concentration of NO_2, then we do get a straight line (Fig. 14.8b). This result shows that the rate is proportional to the square of the concentration and therefore that the rate at any stage can be written

$$\text{Rate of consumption of } NO_2 = k[NO_2]^2$$

From the slope of the straight line in Fig. 14.8b, $k = 0.54\ L{\cdot}mol^{-1}{\cdot}s^{-1}$ at 300.°C.

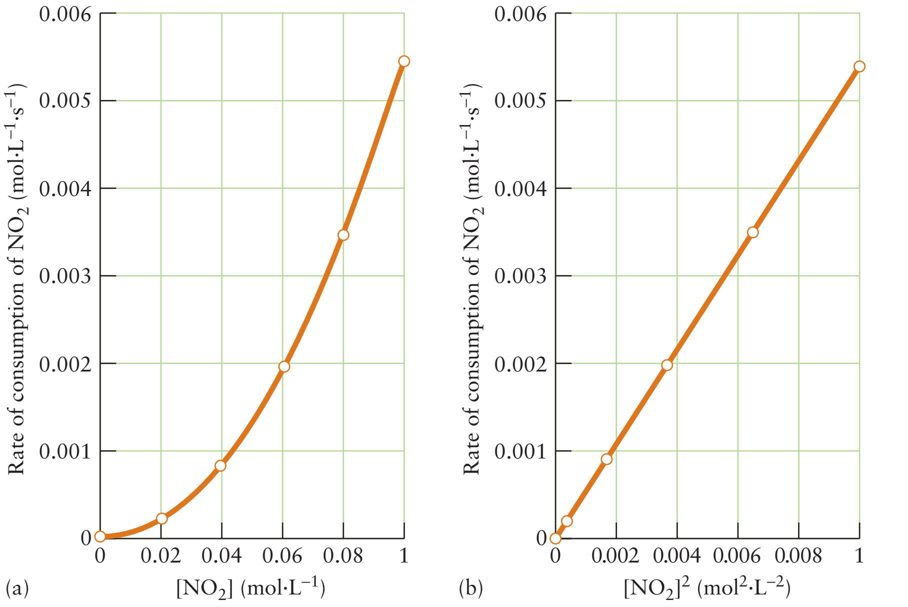

FIGURE 14.8 (a) When the rates of disappearance of NO_2 are plotted against its concentration, a straight line is not obtained. (b) However, a straight line is obtained when the rates are plotted against the square of the concentration, indicating that the rate is directly proportional to the square of the concentration.

The rate laws for the decomposition reactions of N_2O_5 and NO_2 are different, but each has the form

$$\text{Rate} = \text{constant} \times [\text{concentration}]^a \quad (3)$$

with $a = 1$ for the decomposition of N_2O_5 and $a = 2$ for the decomposition of NO_2. The decomposition of N_2O_5 is an example of a **first-order reaction,** because its rate is proportional to the *first* power of the concentration (that is, $a = 1$). The decomposition of NO_2 is an example of a **second-order reaction,** because its rate is proportional to the *second* power of the concentration (that is, $a = 2$). Doubling the concentration of a reactant in a first-order reaction doubles the reaction rate. Doubling the concentration of the reactant in any second-order reaction increases the reaction rate by a factor of $2^2 = 4$.

Most of the reactions that we shall consider are either first or second order in each reactant, but some reactions have other orders (different values of a in Eq. 3). For example, ammonia decomposes into nitrogen and hydrogen on a hot platinum wire:

$$2\,NH_3(g) \longrightarrow N_2(g) + 3\,H_2(g) \quad \text{(C)}$$

Experiments show that the decomposition takes place at a constant rate until all the ammonia has been consumed (Fig. 14.9). Its rate law is therefore

$$\text{Rate of consumption of } NH_3 = k$$

This decomposition is an example of a **zero-order reaction,** a reaction for which the rate is independent of concentration of the reactant (provided some is present).

Zero-order reactions are so called because Rate = $k \times (\text{concentration})^0 = k$.

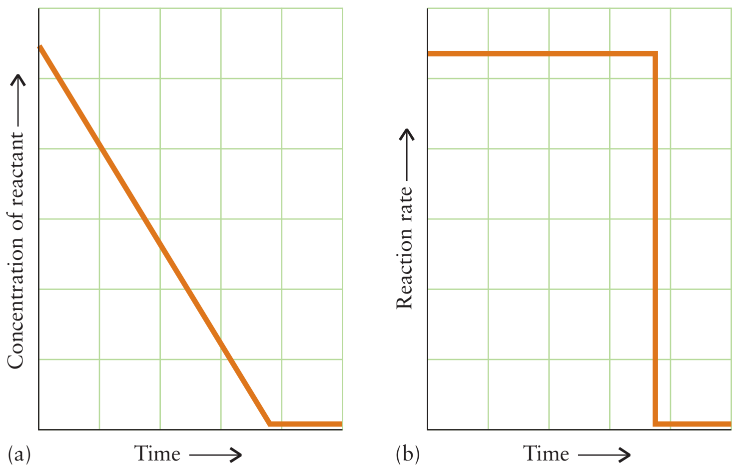

FIGURE 14.9 (a) The concentration of the reactant in a zero-order reaction falls at a constant rate until the reactant is exhausted. (b) The rate of a zero-order reaction is independent of the concentration of the reactant and remains constant until all the reactant has been consumed, when the rate falls abruptly to zero.

We can summarize the rate laws for the three most common orders of reaction as follows:

Order in A	Rate law
0	Rate = k
1	Rate = k[A]
2	Rate = $k[A]^2$

The "Rate" in each expression is the instantaneous rate, and [A] is the concentration of the reactant at the instant of interest. A very important point is the following:

The rate law for a reaction is experimentally determined and cannot in general be inferred from the chemical equation for the reaction.

For instance, both the decomposition of N_2O_5, reaction A, and that of NO_2, reaction B, have a stoichiometric coefficient of 2 for the reactant, but one reaction is first order and the other is second order.

Many reactions have rate laws that depend on the concentrations of more than one reactant. An example is the redox reaction between persulfate ions and iodide ions:

$$S_2O_8^{2-}(aq) + 3\,I^-(aq) \longrightarrow 2\,SO_4^{2-}(aq) + I_3^-(aq) \qquad \textbf{(D)}$$

The rate law of this reaction is found to be

$$\text{Rate of consumption of } S_2O_8^{2-} = k[S_2O_8^{2-}][I^-]$$

We say that the reaction is first order with respect to $S_2O_8^{2-}$ (or "in" $S_2O_8^{2-}$) and first order in I^-. Doubling either the $S_2O_8^{2-}$ ion concentration or the I^- ion concentration doubles the reaction rate. Doubling both concentrations quadruples the reaction rate. We say that the *overall* order of this reaction is 2. In general, if

$$\text{Rate} = k[A]^a[B]^b \cdots \qquad \textbf{(4)*}$$

then the **overall order** is the sum of the powers $a + b + \cdots$.

The units of k depend on the overall order of the reaction and ensure that $k \times (\text{concentration})^a$ has the same units as the rate, namely concentration/time. Thus, when the concentration is expressed in moles per liter and the rate is expressed in $mol{\cdot}L^{-1}{\cdot}s^{-1}$, the units of k are as follows:

Overall order:	1	2	3
Units of *k*:	s^{-1}	$L{\cdot}mol^{-1}{\cdot}s^{-1}$	$L^2{\cdot}mol^{-2}{\cdot}s^{-1}$

and so on. If the concentrations are expressed as partial pressures in kilopascals and the rate is reported in $kPa{\cdot}s^{-1}$, then the units of k are:

Overall order:	1	2	3
Units of *k*:	s^{-1}	$kPa^{-1}{\cdot}s^{-1}$	$kPa^{-2}{\cdot}s^{-1}$

Self-Test 14.3A When the NO concentration is doubled, the rate of the reaction $2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g)$ increases by a factor of 4. When both the O_2 and the NO concentrations are doubled, the rate increases by a factor of 8. What are (a) the reactant orders, (b) the overall order of the reaction, and (c) the units of k if the rate is expressed in moles per liter per second?

[***Answer:*** (a) Second order in NO, first order in O_2; (b) third order overall; (c) $L^2{\cdot}mol^{-2}{\cdot}s^{-1}$]

Self-Test 14.3B When the concentration of 2-bromo-2-methylpropane, C_4H_9Br, is doubled, the rate of the reaction $C_4H_9Br(aq) + OH^-(aq) \longrightarrow C_4H_9OH(aq) + Br^-(aq)$ increases by a factor of 2. When both the C_4H_9Br and the OH^- concentrations are doubled, the rate increase is the same, a factor of 2. What are (a) the reactant orders, (b) the overall order of the reaction, and (c) the units of k if the rate is expressed in moles per liter per second?

The rate laws of reactions are empirical expressions, expressions established experimentally, and we should not be surprised if the orders we find are not simple positive whole numbers. For instance, orders can be negative, as in (concentration)$^{-1}$, corresponding to order −1. Because $[A]^{-1} = 1/[A]$, a negative order implies that the concentration appears in the denominator of the rate law. Increasing the concentration of that species, usually a product, slows down the reaction because the species participates in a reverse reaction. An example is the decomposition of ozone, O_3, in the upper atmosphere:

$$2\ O_3(g) \longrightarrow 3\ O_2(g) \qquad \textbf{(E)}$$

The experimentally determined rate law for this reaction is

Note that a rate law may depend on the concentrations of products as well as those of reactants.

$$\text{Rate} = k\frac{[O_3]^2}{[O_2]} = k[O_3]^2[O_2]^{-1}$$

This rate law tells us that the reaction is slower in regions of the atmosphere where O_2 molecules are abundant than where they are not so abundant. Later on we shall see that this rate law is an important clue to how the reaction takes place.

Some reactions have fractional orders. For example, the oxidation of sulfur dioxide to sulfur trioxide in the presence of platinum,

$$2\ SO_2(g) + O_2(g) \xrightarrow{\text{Pt}} 2\ SO_3(g)$$

is found to have the rate law

$$\text{Rate} = k\frac{[SO_2]}{[SO_3]^{1/2}} = k[SO_2][SO_3]^{-1/2}$$

and an overall order of $1 - \frac{1}{2} = \frac{1}{2}$. The presence of $[SO_3]$ in the denominator means that the reaction slows down as the concentration of product builds up.

EXAMPLE 14.2 Determining the reaction orders and rate law from experimental data

Four experiments were conducted to discover how the initial rate of consumption of BrO_3^- ions in the reaction $BrO_3^-(aq) + 5\ Br^-(aq) + 6\ H_3O^+(aq) \longrightarrow 3\ Br_2(aq) + 9\ H_2O(l)$ varies as the concentrations of the reactants are changed. (a) Use the experimental data in the following table to determine the order of the reaction with respect to each reactant and the overall order. (b) Write the rate law for the reaction and determine the value of *k*.

	Initial concentration (mol·L^{-1})			Initial rate
Experiment	BrO_3^-	Br^-	H_3O^+	((mmol BrO_3^-)·L^{-1}·s^{-1})
1	0.10	0.10	0.10	1.2
2	0.20	0.10	0.10	2.4
3	0.10	0.30	0.10	3.5
4	0.20	0.10	0.15	5.5

PLAN Suppose that the concentration of a substance A is increased but no other concentrations change. From the generic rate law, Rate $= k[A]^a[B]^b$, we know that as the concentration of A increases by the factor *f*, the rate increases by f^a. To isolate the effect of each substance, if possible, compare experiments that differ in the concentration of only one substance at a time.

SOLVE (a) *Order in BrO_3^-:* By comparing experiments 1 and 2, we see that, when the other concentrations are held constant but the concentration of BrO_3^- is doubled ($f = 2$), the rate also doubles, and so $f^a = (2)^a = 2$. Therefore, $a = 1$ and the reaction is first order in BrO_3^-.

Order in Br^-: By comparing experiments 1 and 3, we see that, when the other concentrations are held constant but the concentration of Br^- is changed by a factor of 3.0 ($f = 3.0$),

the rate changes by a factor of 3.5/1.2 = 2.9. Allowing for experimental error, we can deduce that $f^b = (3.0)^b = 3$, and so $b = 1$ and the reaction is first order in Br^-.

Order in H_3O^+: When the concentration of hydronium ions is increased from experiment 2 to experiment 4 by a factor of 1.5 ($f = 1.5$), the rate increases by a factor of $\frac{5.5}{2.4} = 2.3$ when all other concentrations are held constant. Therefore, $f^c = (1.5)^c = 2.3$. To solve the relation $1.5^c = 2.3$ (and in general $f^c = x$), take logarithms of both sides:

From $f^c = x$, $c \ln f = \ln x$, and hence $c = (\ln x)/(\ln f)$,

$$c = \frac{\ln 2.3}{\ln 1.5} = 2.0$$

The reaction is second order in H_3O^+. We can check our result by verifying that $(1.5)^2 = 2.3$. The overall order is 1 + 1 + 2 = 4.

(b) The rate law is

$$\text{Rate of consumption of } BrO_3^- = k[BrO_3^-][Br^-][H_3O^+]^2$$

We find k by substituting the values from one of the experiments into the rate law and solving for k. For example, in experiment 4, we note that the rate of reaction is 5.5 mmol·L^{-1}·s^{-1} = 5.5×10^{-3} mol·L^{-1}·s^{-1}; then we set up the rate law and solve for k:

From k = (Rate of consumption of BrO_3^-)/$[BrO_3^-][Br^-][H_3O^+]^2$,

$$k = \frac{5.5 \times 10^{-3}\ \text{mol·L}^{-1}\text{·s}^{-1}}{(0.20\ \text{mol·L}^{-1}) \times (0.10\ \text{mol·L}^{-1}) \times (0.15\ \text{mol·L}^{-1})^2}$$

$$= 12\ \text{L}^3\text{·mol}^{-3}\text{·s}^{-1}$$

Evaluate The mean value of k calculated from the four experiments is 12 L^3·mol^{-3}·s^{-1}.

Self-Test 14.4A The reaction $2\ NO(g) + O_2(g) \longrightarrow 2\ NO_2(g)$ occurs when automobile exhaust releases NO into the atmosphere. Write the rate law for the consumption of NO and determine the value of k, given the following data:

Experiment	Initial concentration (mol·L^{-1}) NO	O_2	Initial rate ((mol NO)·L^{-1}·s^{-1})
1	0.012	0.020	0.102
2	0.024	0.020	0.408
3	0.024	0.040	0.816

[***Answer:*** Rate of consumption of NO = $k[NO]^2[O_2]$; with the use of Experiment 1, $k = 3.5 \times 10^4$ L^2·mol^{-2}·s^{-1}.]

Self-Test 14.4B The highly toxic gas carbonyl chloride, $COCl_2$ (phosgene), is used to synthesize many organic compounds. Use the following data to write the rate law and determine the value of k for the reaction used to produce carbonyl chloride: $CO(g) + Cl_2(g) \longrightarrow COCl_2(g)$ at a certain temperature:

Experiment	Initial concentration (mol·L^{-1}) CO	Cl_2	Initial rate ((mol $COCl_2$)·L^{-1}·s^{-1})
1	0.12	0.20	0.121
2	0.24	0.20	0.241
3	0.24	0.40	0.682

Hint: One of the orders is not an integer.

The order of a reaction is the power to which the concentration of the species is raised in the rate law; the overall order is the sum of the individual orders.

CONCENTRATION AND TIME

We often want to know how the concentration of a reactant or product varies with time. For example, how long will it take for a pollutant to decay? How much of the alternative fuel methanol can be produced in an hour from coal in an industrial process? How much of a sample of penicillin will be left after 6 months? These questions can be answered by using formulas derived from the experimental rate law for the reactions. An **integrated rate law** gives the concentration of reactants or products at any time after the start of the reaction. Finding the integrated rate law from a rate law is very much like calculating the distance that a car will have traveled from its speed at each moment of the journey.

The integrated rate law for a zero-order reaction is easy to find. Because the rate is constant (at k), the difference in concentration of a reactant from its initial value, $[\mathrm{A}]_0$, is proportional to the time for which the reaction is in progress, and we can write

$$[\mathrm{A}]_0 - [\mathrm{A}] = kt \quad \text{or} \quad [\mathrm{A}] = [\mathrm{A}]_0 - kt$$

As shown in Fig. 14.9a, a plot of concentration against time is a straight line of slope $-k$; the reaction comes to an end when $t = [\mathrm{A}]_0/k$, because then all the reactant has been consumed ($[\mathrm{A}] = 0$).

In the next two sections, we concentrate on first- and second-order rate laws, but the techniques can be used for other reaction orders, too.

14.4 First-Order Integrated Rate Laws

Our aim is to find an expression for the concentration of a reactant A at a time t, given that the initial molar concentration of A is $[\mathrm{A}]_0$ and that the reaction has been found to be first order in A.

HOW DO WE DO THAT?

To find the concentration of reactant A in a first-order reaction at any time after it has begun, we begin by writing the rate law for the consumption of A as

$$\text{Rate of consumption of A} = -\frac{\mathrm{d}[\mathrm{A}]}{\mathrm{d}t} = k[\mathrm{A}]$$

Because an instantaneous rate is a derivative of concentration with respect to time, we can use the techniques of integral calculus to find the change in [A] as a function of time. First, we divide both sides by [A] and multiply through by $-\mathrm{d}t$:

$$\frac{\mathrm{d}[\mathrm{A}]}{[\mathrm{A}]} = -k\mathrm{d}t$$

Now we integrate both sides between the limits $t = 0$ (when $[\mathrm{A}] = [\mathrm{A}]_0$) and the time of interest, t (when $[\mathrm{A}] = [\mathrm{A}]_t$):

$$\int_{[\mathrm{A}]_0}^{[\mathrm{A}]_t} \frac{\mathrm{d}[\mathrm{A}]}{[\mathrm{A}]} = -k\overbrace{\int_0^t \mathrm{d}t}^{t} = -kt$$

To evaluate the integral on the left, we use the standard form

$$\int \frac{\mathrm{d}x}{x} = \ln x + \text{constant}$$

and obtain

$$\int_{[\mathrm{A}]_0}^{[\mathrm{A}]_t} \frac{\mathrm{d}[\mathrm{A}]}{[\mathrm{A}]} = (\ln [\mathrm{A}]_t + \text{constant}) - (\ln [\mathrm{A}]_0 + \text{constant})$$

$$= \ln[\mathrm{A}]_t - \ln [\mathrm{A}]_0 = \ln \frac{[\mathrm{A}]_t}{[\mathrm{A}]_0}$$

We conclude that

$$\ln \frac{[A]_t}{[A]_0} = -kt$$

When we take (natural) antilogarithms of both sides, we obtain $[A]_t/[A]_0 = e^{-kt}$, and therefore

$$[A]_t = [A]_0 e^{-kt}$$

The two equations that we have derived,

$$\ln \frac{[A]_t}{[A]_0} = -kt \qquad \text{(5a)*}$$

$$[A]_t = [A]_0 e^{-kt} \qquad \text{(5b)*}$$

are two forms of the integrated rate law for a first-order reaction. The variation of concentration with time predicted by Eq. 5b is shown in Fig. 14.10. This behavior is called **exponential decay** because the concentration of A depends on an exponential function of time. Initially the concentration changes rapidly, but it changes more slowly as time goes on and the reactant is used up.

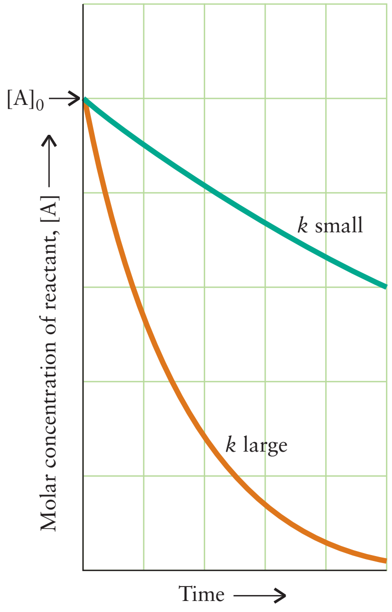

FIGURE 14.10 The graph of the concentration of a reactant in a first-order reaction is an exponential decay, as shown here. The larger the rate constant, the faster the decay from the same initial concentration.

EXAMPLE 14.3 Calculating a concentration from a first-order integrated rate law

What concentration of N_2O_5 remains 10.0 min (600. s) after the start of its decomposition at 65°C (in reaction **A**) when its initial concentration was 0.040 mol·L^{-1}? See Table 14.1 for the rate law.

Anticipate Because the reactant decays with time, we should expect a concentration that is lower than the initial value, but to assess the change we must do the calculation.

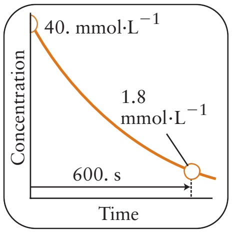
PLAN First identify the order of the reaction. If the reaction is first order in the specified reactant, use the exponential form of the first-order rate law (Eq. 5b) to find the new concentration of the reactant.

SOLVE

The reaction and its rate law are

$$2\,N_2O_5(g) \longrightarrow 4\,NO_2(g) + O_2(g)$$

Rate of decomposition of $N_2O_5 = k[N_2O_5]$, with $k = 5.2 \times 10^{-3}\ s^{-1}$. Therefore, the reaction is first order in N_2O_5.



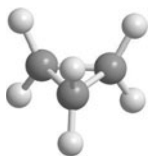
From $[A]_t = [A]_0 e^{-kt}$,

$$[N_2O_5]_t = (0.040\ mol{\cdot}L^{-1}) \times e^{-(5.2\times10^{-3}s^{-1}) \times (600.\ s)}$$
$$= 0.0018\ mol{\cdot}L^{-1}$$

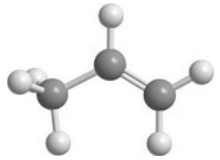
Evaluate We can conclude that after 600. s, the concentration of N_2O_5 will have fallen from its initial value of 0.040 mol·L^{-1} to 0.0018 mol·L^{-1} (1.8 mmol·L^{-1}).

Self-Test 14.5A The rate law for the decomposition $2\,N_2O(g) \longrightarrow 2\,N_2(g) + O_2(g)$ is Rate of decomposition of $N_2O = k[N_2O]$. Calculate the concentration of N_2O remaining after the reaction has continued at 780°C for 100. ms, if the initial concentration of N_2O is 0.20 mol·L^{-1} and $k = 3.4\ s^{-1}$.

[***Answer:*** 0.14 mol·L^{-1}]



1 Cyclopropane, C_3H_6



2 Propene, C_3H_6

We mentioned in Section 14.2 that there is a better way of determining rate constants than trying to draw tangents to curves: this is it.

Self-Test 14.5B Calculate the concentration of cyclopropane, C_3H_6 (**1**), remaining after the conversion into its isomer propene (**2**): $C_3H_6(g) \longrightarrow CH_3{-}CH{=}CH_2(g)$ has continued at 773 K for 200. s, if the initial concentration of C_3H_6 is 0.100 $mol{\cdot}L^{-1}$ and $k = 6.7 \times 10^{-4}\ s^{-1}$. The rate law is Rate of conversion of $C_3H_6 = k[C_3H_6]$.

An important application of an integrated rate law is to confirm that a reaction is in fact first order and to measure its rate constant. From Eq. 5a, we can write

$$\ln [A]_t = \ln [A]_0 - kt \qquad (6)$$

This equation has the form of an equation for a straight line (see Appendix 1E):

$$y = \text{intercept} + \text{slope} \times x$$

Therefore, if we plot $\ln [A]_t$ as a function of t, we should get a straight line with slope $-k$ and intercept $\ln [A]_0$.

EXAMPLE 14.4 Measuring a rate constant

When cyclopropane (C_3H_6, see **1**) is heated to 500.°C (773 K), it changes into an isomer, propene (see **2**). The following data show the concentration of cyclopropane at a series of times after the start of the reaction. Confirm that the reaction is first order in C_3H_6 and calculate the rate constant.

t (min)	0	5	10.	15
$[C_3H_6]_t$ ($mol{\cdot}L^{-1}$)	1.50×10^{-3}	1.24×10^{-3}	1.00×10^{-3}	0.83×10^{-3}

PLAN We need to plot the natural logarithm of the reactant concentration as a function of t. If we get a straight line, the reaction is first order and the slope of the graph is $-k$. If the plot is not linear, then the reaction is not first order in the specified reactant. We could use a spreadsheet program or the Living Graph "Determination of Rate Constant (first-order rate law)" on the Web site for this book to make the plot.

SOLVE For the graphical procedure, begin by setting up the following table:

t(min)	0	5	10.	15
$\ln [C_3H_6]_t$	−6.50	−6.69	−6.91	−7.09

The points are plotted in Fig. 14.11. The graph is a straight line, confirming that the reaction is first order in cyclopropane. When we use points A and B on the plot, the slope of the line is

$$\text{Slope} = \frac{(-7.02) - (-6.56)}{(13.3 - 1.7)\ \text{min}} = -0.040\ \text{min}^{-1}$$

Therefore, because $k = -\text{slope}$, $k = 0.040\ \text{min}^{-1}$.

Evaluate The value we have calculated is equivalent to $k = 6.7 \times 10^{-4}\ s^{-1}$, the value in Table 14.1.

A note on good practice: Be sure to determine and include the appropriate units for k.

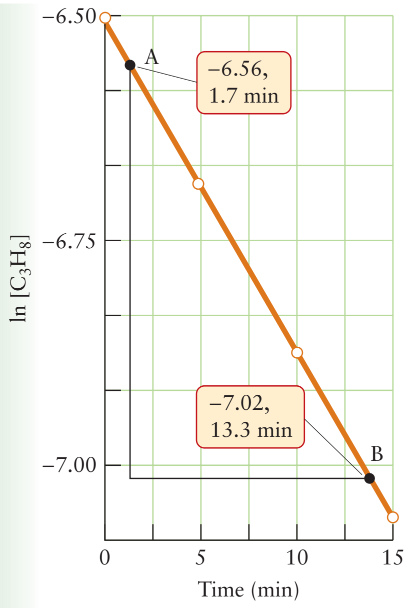


FIGURE 14.11 We can test for a first-order reaction by plotting the natural logarithm of the reactant concentration against time. The graph is linear if the reaction is first order. The slope of the line, which is calculated here for the system in Example 14.4 by using the points A and B, is equal to the negative of the rate constant.

Living Graph 14.11

Self-Test 14.6A Data on the decomposition of N_2O_5 at 25°C are

t(min)	0	200.	400.
$[N_2O_5]_t$ ($mol{\cdot}L^{-1}$)	15.0×10^{-3}	9.6×10^{-3}	6.2×10^{-3}
	600.	800.	1000.
	4.0×10^{-3}	2.5×10^{-3}	1.6×10^{-3}

Confirm that the reaction is first order and find the value of k for the reaction $N_2O_5(g) \longrightarrow$ products.

[***Answer:*** The plot of $\ln [N_2O_5]$ against time is linear, and so the reaction is first order; $k = 2.2 \times 10^{-3}\ \text{min}^{-1}$.]

Self-Test 14.6B Azomethane, $CH_3N_2CH_3$, decomposes to ethane and nitrogen gas in the reaction $CH_3N_2CH_3(g) \longrightarrow CH_3CH_3(g) + N_2(g)$. The reaction was followed at 460. K by measuring the partial pressure of azomethane over time:

t (s)	0.	1000.	2000.	3000.	4000.
$P_{CH_3N_2CH_3}$ (Torr)	8.20×10^{-2}	5.72×10^{-2}	3.99×10^{-2}	2.78×10^{-2}	1.94×10^{-2}

Confirm that the reaction is first order of the form Rate $= kP$, where P is the partial pressure of azomethane, and find the value of k.

EXAMPLE 14.5 Predicting how long it will take for a concentration to change

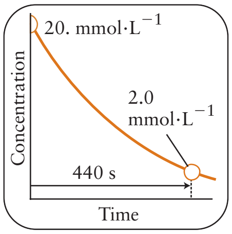
A sample of N_2O_5 is allowed to decompose as in reaction **A**, $2\ N_2O_5(g) \longrightarrow 4\ NO_2(g) + O_2(g)$. How long will it take for the concentration of N_2O_5 to decrease from 20. mmol·L^{-1} to 2.0 mmol·L^{-1} at 65°C? Use the data in Table 14.1.

PLAN First, identify the order of the reaction in N_2O_5 by referring to Section 14.3 or Table 14.1. If the reaction is first order, rearrange Eq. 5a into an equation for t in terms of the given concentrations. Then substitute the numerical value of the rate constant and the concentration data and evaluate t.

SOLVE The reaction is first order with $k = 5.2 \times 10^{-3}\ s^{-1}$ at 65°C (338 K). Therefore,

From $\ln([A]_t/[A]_0) = -kt$ rearranged into $t = (1/k)\ln([A]_0/[A]_t)$,

$$t = \frac{1}{5.2 \times 10^{-3}\ s^{-1}} \ln \frac{20.\ mmol \cdot L^{-1}}{2.0\ mmol \cdot L^{-1}}$$
$$= 4.4 \times 10^2\ s$$



Self-Test 14.7A How long does it take for the concentration of A to decrease to 1.0% of its initial value in a first-order reaction of the form A $\longrightarrow$ products with $k = 1.0\ s^{-1}$?

[*Answer:* 4.6 s]

Self-Test 14.7B Cyclopropane isomerizes to propene in a first-order process. How long does it take for the concentration of cyclopropane to decrease from 1.0 mol·L^{-1} to 0.0050 mol·L^{-1} at 500.°C? Use the data in Table 14.1.

We have seen that some rate laws depend on the concentration of more than one species. For instance, oxidation of iodide ions by persulfate ions (reaction D) follows the rate law

$$\text{Rate of consumption of } S_2O_8^{2-} = k[S_2O_8^{2-}][I^-]$$

In such cases, we can simplify the analysis by ensuring that one species remains effectively at the same concentration throughout the reaction and so can be treated as a constant. One way to do this is to start with persulfate ions in such a high concentration that their concentration barely changes in the course of the reaction. For instance, the concentration of persulfate ions might be 100 times as great as the concentration of iodide ions; so, even when all the iodide ions have been oxidized, the persulfate concentration is almost the same as it was at the beginning of the reaction. Because $[S_2O_8^{2-}]$ is virtually constant, we can write the rate law as

$$\text{Rate of consumption of } S_2O_8^{2-} = k'[I^-]$$

where $k' = k[S_2O_8^{2-}]$, another constant. We have turned the actual second-order reaction into a **pseudo-first-order reaction,** a reaction that is effectively first order. The rate

law for a pseudo-first-order reaction is much easier to analyze than the true rate law because it depends on the concentration of only one substance and the variation of iodide ion concentration with time can be treated in the same way as a true first-order reaction. Then, by knowing the concentration of $S_2O_8{}^{2-}$ ions we have used in the experiment, we can deduce the value of the overall rate constant from $k = k'/[S_2O_8{}^{2-}]$,

In a first-order reaction, the concentration of reactant decays exponentially with time. To verify that a reaction is first order, plot the natural logarithm of its concentration as a function of time and expect a straight line; the slope of the straight line is $-k$.

14.5 Half-Lives for First-Order Reactions

The **half-life,** $t_{1/2}$, of a substance is the time needed for its concentration to fall to one-half its initial value. Knowing the half-lives of pollutants such as chlorofluorocarbons allows us to assess their environmental impact. If their half-lives are short, they may not survive long enough to reach the stratosphere, where they can destroy ozone. Half-lives are also important in planning storage systems for radioactive materials, because the decay of radioactive nuclei is a first-order process (see Section 17.7).

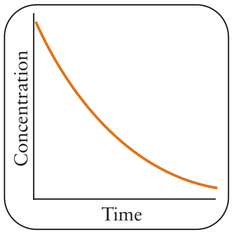
We already know that the higher the value of k, the more rapid the consumption of a reactant. Therefore, we should be able to deduce a relation for a first-order reaction that shows that the greater the rate constant, the shorter the half-life.

HOW DO WE DO THAT?

To find the relation between the rate constant and the half-life of a first-order reaction, we begin by rearranging Eq. 5a into an expression for the time needed to reach a given concentration:

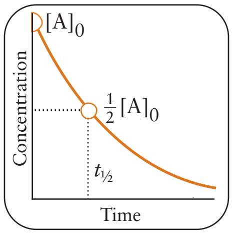
From $\ln([A]_t/[A]_0) = -kt$,

$$t = \frac{1}{k}\ln\frac{[A]_0}{[A]_t}$$



Now set $t = t_{1/2}$ and $[A]_t = \frac{1}{2}[A]_0$,

$$t_{1/2} = \frac{1}{k}\ln\frac{[A]_0}{\frac{1}{2}[A]_0} = \frac{1}{k}\ln 2$$



Notice that the initial concentration has canceled.

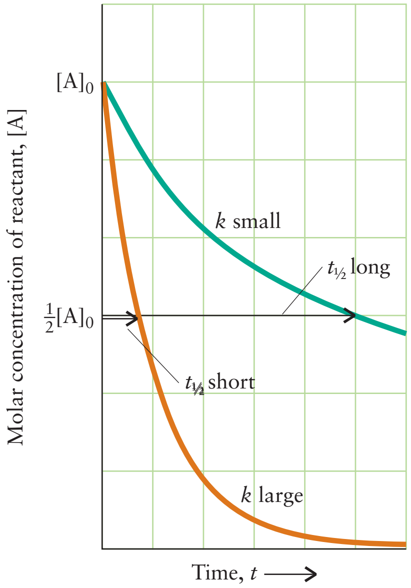


FIGURE 14.12 The change in concentration of the reactant in two first-order reactions plotted on the same graph. When the first-order rate constant is large, the half-life of the reactant is short, because the exponential decay of the concentration of the reactant is then fast.

We have shown that, for the rate law Rate of consumption of A = $k[A]$,

$$t_{1/2} = \frac{\ln 2}{k} \qquad (7)^*$$

with $\ln 2 = 0.693\ldots$. As we anticipated, the greater the value of the rate constant k, the shorter the half-life for the reaction (Fig. 14.12). Note that the half-life of a first-order reaction depends only on the rate constant and not on the concentration. Therefore, it has the same value at all stages of the reaction: whatever the reactant concentration might be at any stage of the reaction, it takes the same time ($t_{1/2}$) for that concentration to halve.

EXAMPLE 14.6 Using a half-life to calculate the amount of reactant remaining

In 1989 a teenager in Ohio was poisoned by breathing vapors from spilled mercury. The mercury level in his urine, which is proportional to its concentration in his body, was found to be 1.54 $mg{\cdot}L^{-1}$. Mercury(II) is eliminated from the body by a first-order process that has a half-life of 6 days (6 d). What would be the concentration of mercury(II) in the patient's urine in milligrams per liter after 30 d if therapeutic measures were not taken?

Anticipate Thirty days is five half-lives, so we should expect that most of the mercury will have been eliminated.

PLAN The level of mercury(II) in the urine can be predicted by using the integrated first-order rate law, Eq. 5b. To use this equation, we need the rate constant. Therefore, start by calculating the rate constant from the half-life (Eq. 7) and substitute the result into Eq. 5b.

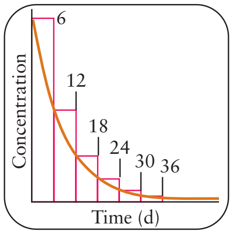
SOLVE

From $t_{1/2} = (\ln 2)/k$ in the form $k = (\ln 2)/t_{1/2}$,

$$k = \frac{\ln 2}{6\text{ d}} = \frac{\ln 2}{6}\text{ d}^{-1}$$

From $[A] = [A]_0 e^{-kt}$,

$$[A]_t = [A]_0 e^{-\{(\ln 2)/6\text{ d}^{-1}\}\times(30\text{ d})}$$
$$= (1.54\text{ mg}{\cdot}\text{L}^{-1})e^{-\{(\ln 2)\times 30/6\}}$$
$$= 0.05\text{ mg}{\cdot}\text{L}^{-1}$$



Evaluate The concentration of mercury in the urine is therefore 0.05 $mg{\cdot}L^{-1}$. As expected, this is a very small value.

A note on good practice: Note that, because exponential functions e^x are so sensitive to the value of x, we avoid rounding errors by leaving the numerical calculation to a single final step.

Self-Test 14.8A In 1972, grain treated with methyl mercury was released for human consumption in Iraq, resulting in 459 deaths. The half-life of methyl mercury in body tissues is 70. d. How many days are required for the amount of methyl mercury to drop to 10.% of the original value after ingestion?

[***Answer:*** 230 d]

Self-Test 14.8B Soil at the Rocky Flats Nuclear Processing Facility in Colorado was found to be contaminated with radioactive plutonium-239, which has a half-life of 24 ka (2.4×10^4 years). The soil was loaded into drums for storage. How many years must pass before the radioactivity drops to 20.% of its initial value?

The concentration of the reactant does not appear in Eq. 7: for a first-order reaction, the half-life is independent of the initial concentration of the reactant. That is, it is constant: regardless of the initial concentration of reactant, half the reactant will have been consumed in the time given by Eq. 7. It follows that the concentration of A can be used as its "initial" concentration at any stage of the reaction: if at some stage the concentration of A happens to be [A], then after a further time $t_{1/2}$, the concentration of A will have fallen to $\frac{1}{2}$[A]; after a further $t_{1/2}$ it will have fallen to $\frac{1}{4}$; and so on (Fig. 14.13). In general, at any stage of the reaction, the concentration remaining after n half-lives is $\left(\frac{1}{2}\right)^n[A]$. For example, in Example 14.6, because 30 days corresponds to 5 half-lives, after that interval $[A]_t = \left(\frac{1}{2}\right)^5[A]_0$, or $[A]_0/32$, which evaluates to 3%, the same as the result obtained in the example.

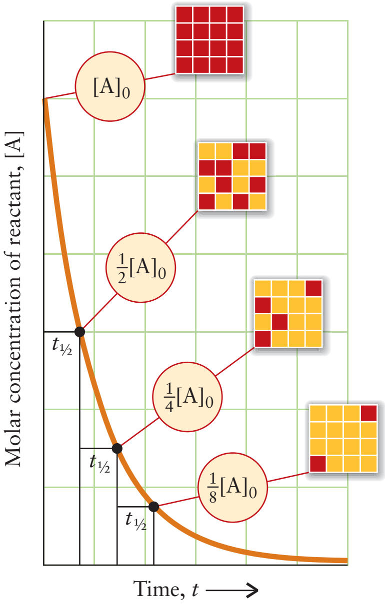


FIGURE 14.13 For first-order reactions, the half-life is the same whatever the concentration at the start of the chosen period. Therefore, it takes one half-life to fall to half the initial concentration, two half-lives to fall to one-fourth the initial concentration, three half-lives to fall to one-eighth, and so on. The boxes portray the composition of the reaction mixture at the end of each half-life; the red squares represent the reactant A and the yellow squares represent the product.

Self-Test 14.9A Calculate (a) the number of half-lives and (b) the time required for the concentration of N_2O to fall to one-eighth of its initial value in a first-order decomposition at 1000. K. Consult Table 14.1 for the rate constant.

[***Answer:*** (a) 3 half-lives; (b) 2.7 s]

Self-Test 14.9B Calculate (a) the number of half-lives and (b) the time required for the concentration of C_2H_6 to fall to one-sixteenth of its initial value as it dissociates into CH_3 radicals at 973 K. Consult Table 14.1 for the rate constant.

The half-life of a first-order reaction is characteristic of the reaction and independent of the initial concentration. It is inversely proportional to the rate constant of the reaction.

14.6 Second-Order Integrated Rate Laws

Now we derive the integrated rate law for second-order reactions with the rate law

$$\text{Rate of consumption of A} = k[\text{A}]^2$$

HOW DO WE DO THAT?

To obtain the integrated rate law for a second-order reaction, we recognize that the rate law is a differential equation and write it as

$$-\frac{d[\text{A}]}{dt} = k[\text{A}]^2$$

After division by $[\text{A}]^2$ and multiplication by $-dt$, this equation becomes

$$\frac{d[\text{A}]}{[\text{A}]^2} = -k\,dt$$

To integrate this equation, we use the same limits as in the first-order case:

$$\int_{[\text{A}]_0}^{[\text{A}]_t} \frac{d[\text{A}]}{[\text{A}]^2} = -k\overbrace{\int_0^t dt}^{t} = -kt$$

This time we need the integral

$$\int \frac{dx}{x^2} = -\frac{1}{x} + \text{constant}$$

and write the integral on the left as

$$\int_{[\text{A}]_0}^{[\text{A}]_t} \frac{d[\text{A}]}{[\text{A}]^2} = \left(-\frac{1}{[\text{A}]_t} + \text{constant}\right) - \left(-\frac{1}{[\text{A}]_0} + \text{constant}\right)$$

$$= \frac{1}{[\text{A}]_0} - \frac{1}{[\text{A}]_t}$$

Thus, we obtain

$$\frac{1}{[\text{A}]_t} - \frac{1}{[\text{A}]_0} = kt, \text{ which can be rearranged into } [\text{A}]_t = \frac{[\text{A}]_0}{1 + kt[\text{A}]_0}$$

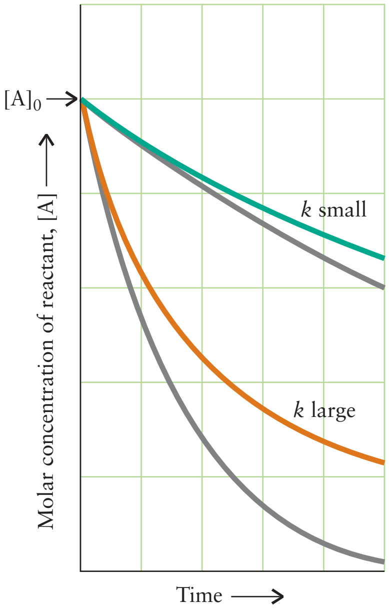

FIGURE 14.14 The characteristic shapes of the time dependence of the concentration of a reactant during a second-order reaction. The larger the rate constant, k, the greater is the dependence of the rate on the concentration of the reactant. The lower gray lines are the curves for first-order reactions with the same initial rates as for the corresponding second-order reactions. Note how the concentrations for second-order reactions fall away much less rapidly at longer times than those for first-order reactions do.

The two equations that we have derived are

$$\frac{1}{[\text{A}]_t} - \frac{1}{[\text{A}]_0} = kt \qquad \textbf{(8a)*}$$

$$[\text{A}]_t = \frac{[\text{A}]_0}{1 + kt[\text{A}]_0} \qquad \textbf{(8b)*}$$

Equation 8b is plotted in Fig. 14.14. We see that the concentration of the reactant decreases rapidly at first but then changes more slowly than it would for a first-order

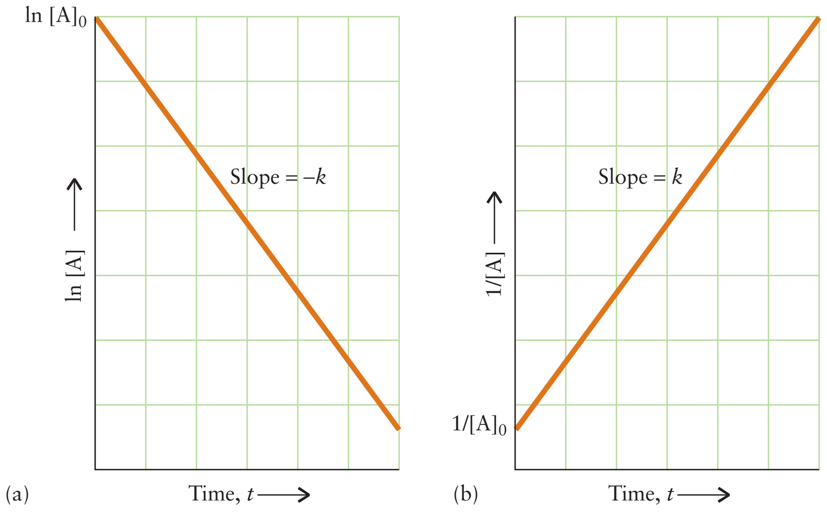

FIGURE 14.15 The plots that allow the determination of reaction order. (a) If a plot of ln [A] against time is a straight line, the reaction is first order. (b) If a plot of 1/[A] against time is a straight line, the reaction is second order.

Living Graph 14.15

reaction with the same initial rate. This slowing down of second-order reactions has important environmental consequences: because many pollutants degrade by second-order reactions, they remain at low concentration in the environment for long periods. Equation 8a can be written in the form of a linear equation:

$$\overbrace{\frac{1}{[A]_t}}^{y} = \overbrace{\frac{1}{[A]_0}}^{\text{intercept}} + \overbrace{k}^{\text{slope}}\, t \qquad (8c)^*$$

Therefore, to determine whether a reaction is second order in a reactant, we plot the inverse of the concentration against the time and see whether we get a straight line. If the line is straight, then the reaction is second order and the slope of the line is equal to k (Fig. 14.15).

As we have seen for first- and second-order rate laws, each integrated rate law can be rearranged into an equation that, when plotted, gives a straight line and the rate constant can then be obtained from the slope of the plot. Table 14.2 summarizes the relationships to use.

TABLE 14.2 Rate Law Summary

	Order of reaction		
	0	1	2
Rate law	Rate $= k$	Rate $= k[A]$	Rate $= k[A]^2$
Integrated rate law	$[A]_t = -kt + [A]_0$	$[A]_t = [A]_0e^{-kt}$	$[A]_t = \frac{[A]_0}{1 + [A]_0 t}$ $\frac{1}{[A]_t} = \frac{1}{[A]_0} + kt$
Plot to determine order			Slope of the line plotted	$-k$	$-k$	k
Half-life	$t_{1/2} = \frac{[A]_0}{2k}$ (not used)	$t_{1/2} = \frac{\ln 2}{k} \approx \frac{0.693}{k}$	$t_{1/2} = \frac{1}{k[A]_0}$ (not used)

A second-order reaction has a long tail of low concentration at long reaction times. The half-life of a second-order reaction is inversely proportional to the concentration of the reactant.

REACTION MECHANISMS

Knowing how a reaction takes place at the molecular level provides answers to many important questions. For example, what controls the rate of formation of the DNA double helix from its individual strands? What molecular events convert ozone into oxygen or turn a mixture of fuel and air into carbon dioxide and water when it ignites in an engine? In the following sections we see how to use the rate law for a reaction as a window into these changes.

14.7 Elementary Reactions

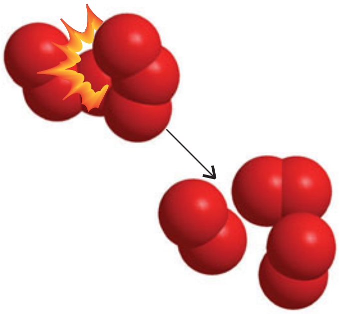

FIGURE 14.16 A representation of a proposed one-step mechanism for the decomposition of ozone in the atmosphere. This reaction takes place in a single bimolecular collision.

We stressed in Section 14.3 that we cannot in general write a rate law from a chemical equation. The reason is that all but the simplest reactions are the outcome of several, and sometimes many, steps called **elementary reactions.** Each elementary reaction describes a distinct event, often a collision of particles. To describe how a reaction takes place, we propose a **reaction mechanism,** a sequence of elementary reactions or steps that we believe take place as reactants are transformed into products.

Although several different mechanisms might be proposed for a reaction, rate measurements can be used to eliminate some of them. For example, in the decomposition of ozone in reaction E (Section 14.3), $2\ O_3(g) \longrightarrow 3\ O_2(g)$, we could imagine the reaction taking place two different ways:

One-step mechanism: Two O_3 molecules collide and rearrange into three O_2 molecules (Fig. 14.16):

$$O_3 + O_3 \longrightarrow O_2 + O_2 + O_2$$

Two-step mechanism: In the first step, an O_3 molecule is energized by solar radiation and dissociates into an O atom and an O_2 molecule. In the second step, the O atom attacks another O_3 molecule to produce two more O_2 molecules (Fig. 14.17):

Step 1 $O_3 \longrightarrow O_2 + O$

Step 2 $O + O_3 \longrightarrow O_2 + O_2$

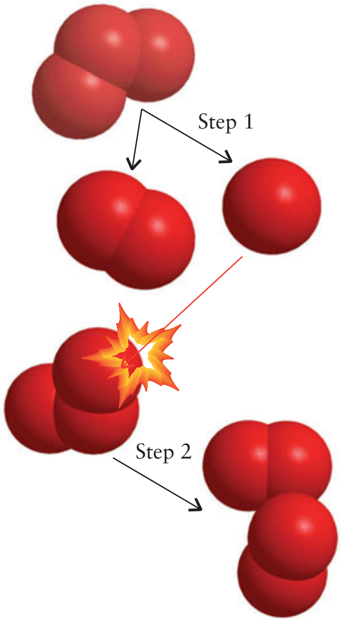

FIGURE 14.17 An alternative, two-step mechanism for the decomposition of ozone. In the first step, an energized ozone molecule shakes off an oxygen atom. In the second step, that oxygen atom attacks another ozone molecule.

The free O atom in the second mechanism is a **reaction intermediate,** a species that plays a role in a reaction but does not appear in the chemical equation for the overall reaction: it is produced in one step but is used up in a later step. The two equations for the elementary reactions add together to give the equation for the overall reaction.

A note on good practice: The chemical equations for elementary reaction steps are written without the state symbols. They differ from the overall chemical equation, which summarizes bulk behavior, because they show how *individual* atoms and molecules take part in the reaction. We do not use stoichiometric coefficients for elementary reactions. Instead, to emphasize that we are depicting individual molecules, we write the formula as many times as required.

Elementary reactions are classified according to their **molecularity,** the number of reactant molecules, atoms, or ions taking part in a specified elementary reaction. The equation for the first step in the two-step mechanism for the decomposition of ozone ($O_3 \longrightarrow O_2 + O$) is an example of a **unimolecular reaction,** because only one reactant molecule participates. We can picture an ozone molecule as acquiring energy from sunlight and vibrating so vigorously that it shakes itself apart. In the second step of the two-step mechanism, the O atom produced by the dissociation of O_3 goes on to attack another O_3 molecule ($O + O_3 \longrightarrow O_2 + O_2$). This elementary reaction is an example of a **bimolecular reaction,** because two reactant species come together to react. The molecularity of a unimolecular reaction is 1 and that of a bimolecular reaction is 2.

Any forward reaction that can take place is also accompanied, in principle at least, by the corresponding reverse reaction. Therefore, the unimolecular decay of O_3 in step 1 of the two-step mechanism is accompanied by the formation reaction

$$O_2 + O \longrightarrow O_3$$

The reverse of the reaction in step 1 is bimolecular. Similarly, the bimolecular attack of O on O_3 in step 2 of the two-step mechanism is accompanied by its bimolecular reverse reaction

$$O_2 + O_2 \longrightarrow O + O_3$$

These two equations add up to give the reverse of the overall equation, $3\ O_2(g) \longrightarrow 2\ O_3(g)$. The forward and reverse reactions jointly provide a mechanism for reaching dynamic equilibrium between the reactants and the products in the overall process.

The reverse of the single elementary step in the one-step mechanism is

$$O_2 + O_2 + O_2 \longrightarrow O_3 + O_3$$

This step is an example of a **termolecular reaction,** an elementary reaction requiring the simultaneous collision of three molecules. Termolecular reactions are uncommon, because it is very unlikely that three molecules will collide simultaneously with one another under normal conditions.

Self-Test 14.10A What is the molecularity of each elementary reaction: (a) $C_2N_2 \longrightarrow CN + CN$; (b) $NO_2 + NO_2 \longrightarrow NO + NO_3$?

[***Answer:*** (a) Unimolecular; (b) bimolecular]

Self-Test 14.10B What is the molecularity of each elementary reaction: (a) $C_2H_5Br + OH^- \longrightarrow C_2H_5OH + Br^-$; (b) $Br_2 \longrightarrow Br + Br$?

Many reactions take place by a series of elementary reactions. The molecularity of an elementary reaction is the number of reactant particles that take part in the step.

14.8 The Rate Laws of Elementary Reactions

To verify that a proposed reaction mechanism agrees with experimental data, we construct the overall rate law implied by the mechanism and check to see whether it is consistent with the experimentally determined rate law. However, although the constructed rate law and the experimental rate law may be the same, the proposed mechanism may still be incorrect because some other mechanism may also lead to the same rate law. Kinetic information can only support a proposed mechanism; it can never prove that a mechanism is correct. The acceptance of a suggested mechanism is more like the process of proof in an ideal court of law than a proof in mathematics, with evidence being assembled to give a convincing, consistent picture.

To construct an overall rate law from a mechanism, we write the rate law for each of the elementary reactions that have been proposed; then combine them—in a way we shall explain—into an overall rate law. Because an elementary reaction shows how that step of the reaction occurs, we can write its rate law (but *not* the rate law for the overall reaction) from its chemical equation, with each power of concentration ([A], $[A]^2$, etc.) in the rate law being the same as the number of particles of a given type participating in the step, as summarized in Table 14.3.

TABLE 14.3 Rate Laws of Elementary Reactions

Molecularity	Elementary reaction		Rate law
1	$A \longrightarrow$	products	rate = $k[A]$
2	$A + B \longrightarrow$	products	rate = $k[A][B]$
	$A + A \longrightarrow$	products	rate = $k[A]^2$
3	$A + B + C \longrightarrow$	products	rate = $k[A][B][C]$
	$A + A + B \longrightarrow$	products	rate = $k[A]^2[B]$
	$A + A + A \longrightarrow$	products	rate = $k[A]^3$

To see how this works in practice, let's write the rate laws for the steps in a mechanism proposed for the gas-phase oxidation of NO to NO_2. Its overall rate law has been determined experimentally:

$$2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g) \qquad \text{Rate of formation of } NO_2 = k[NO]^2[O_2]$$

The following mechanism has been proposed for the reaction.

Step 1 A fast bimolecular dimerization and its reverse:

$$NO + NO \longrightarrow N_2O_2 \qquad \text{Rate of formation of } N_2O_2 = k_1[NO]^2$$

$$N_2O_2 \longrightarrow NO + NO \qquad \text{Rate of formation of } N_2O_2 = k_1'[N_2O_2]$$

Step 2 A slow bimolecular reaction in which an O_2 molecule collides with the dimer:

$$O_2 + N_2O_2 \longrightarrow NO_2 + NO_2 \quad \text{Rate of consumption of } N_2O_2 = k_2[N_2O_2][O_2]$$

The reverse of step 2 is too slow to include.

To evaluate the plausibility of this mechanism, we need to construct the overall rate law it implies. First, we identify any elementary reaction that results in the overall product (NO_2) and write the equation for the net rate of product formation. In this case, NO_2 is formed only in step 2, and so

$$\text{Rate of formation of } NO_2 = 2k_2[N_2O_2][O_2]$$

The factor of 2 appears in the rate law because two NO_2 molecules are formed from each N_2O_2 molecule consumed. This expression is not yet an acceptable rate law for the overall reaction because it includes the concentration of an intermediate, N_2O_2, and intermediates do not appear in the overall rate law for a reaction.

To eliminate the concentration of the intermediate N_2O_2 we proceed as follows. First, we write the expression for its net rate of formation. According to the mechanism, N_2O_2 is formed in the forward reaction in step 1, removed in the reverse reaction, and removed in step 2. Therefore the net rate of its formation is

$$\text{Net rate of formation of } N_2O_2 = \overset{\text{Step 1}}{k_1[NO]^2} - \overset{\text{Step 1, reverse}}{k_1'[N_2O_2]} - \overset{\text{Step 2}}{k_2[N_2O_2][O_2]}$$

Now we make the **steady-state approximation,** that any intermediate remains at a constant, low concentration. The justification for this approximation is that the intermediate is so reactive that it reacts as soon as it is formed. Because the concentration of the intermediate is constant, its net rate of formation is zero, and the previous equation becomes

$$k_1[NO]^2 - k_1'[N_2O_2] - k_2[N_2O_2][O_2] = 0$$

This equation, which can be written

$$k_1[NO]^2 - (k_1' + k_2[O_2])[N_2O_2] = 0$$

can be rearranged to find the concentration of N_2O_2:

$$[N_2O_2] = \frac{k_1[NO]^2}{k_1' + k_2[O_2]}$$

Now that we have an expression for $[N_2O_2]$, we can substitute that expression into the rate law:

$$\text{Rate of formation of } NO_2 = 2k_2[N_2O_2][O_2] = \frac{2k_1k_2[NO]^2[O_2]}{k_1' + k_2[O_2]} \qquad (9)$$

The rate law that we have derived is not the same as the experimental one. We have stressed that a reaction mechanism is plausible only if its predictions are in line with experimental results; so should we discard our proposal? Before doing so, it is always wise to explore whether under certain conditions the predictions do in fact agree with experimental data. In this case, if the rate of step 2 is very slow relative to the rapid equilibrium in step 1—so that $k_1'[N_2O_2] \gg k_2[N_2O_2][O_2]$, which implies that $k_1' \gg k_2[O_2]$ when we cancel the $[N_2O_2]$ on each side of the inequality—we can ignore

the term $k_2[O_2]$ in the denominator of Eq. 9. With this approximation, the rate law simplifies to

$$\text{Rate of formation of } NO_2 = \frac{2k_1k_2}{k_1'}[NO]^2[O_2] \tag{10a}$$

which agrees with the experimentally determined rate law if we write

$$k = \frac{2k_1k_2}{k_1'} \tag{10b}$$

The proposed mechanism is therefore consistent with experiment.

The assumption that the rate of consumption of the intermediate in the slow step is insignificant relative to its rates of formation and decomposition in the first step is called a **pre-equilibrium condition.** A pre-equilibrium arises when an intermediate is formed and sustained in a rapid formation reaction and its reverse. The calculation of the rate law is then much simpler. For instance, if we propose that the first step in the NO oxidation gives rise to a pre-equilibrium, we would write

$$NO + NO \rightleftharpoons N_2O_2 \qquad K = \frac{[N_2O_2]}{[NO]^2}$$

This equilibrium implies that $[N_2O_2] = K[NO]^2$. The rate of formation of NO_2 is therefore

$$\text{Rate of formation of } NO_2 = 2k_2[N_2O_2][O_2] = 2k_2K[NO]^2[O_2]$$

As before, the mechanism gives rise to an overall third-order rate law, in agreement with experiment. Although this procedure is much simpler than the steady-state approach, it is less flexible: it is more difficult to extend to more complex mechanisms and the conditions under which the approximation is valid are harder to establish.

The slowest elementary step in a sequence of reactions that governs the overall rate of formation of products—in our example, the reaction between O_2 and the intermediate N_2O_2 in step 2—is called the **rate-determining step** of the reaction (Fig. 14.18). A rate-determining step is like a slow ferry on the route between two cities. The rate at which the traffic arrives at its destination is governed by the rate at which it is ferried across the river, because that part of the journey is much slower than any of the others. Steps that follow the rate-determining step take place as soon as the intermediate has been formed and have a negligible effect on the overall rate. Therefore, they can be ignored when writing the overall rate law from the mechanism.

In simple cases, we can identify the rate-determining step by considering the experimental rate law. For example, the reaction

$$(CH_3)_3CBr(sol) + OH^-(sol) \longrightarrow (CH_3)_3COH(sol) + Br^-(sol)$$

takes place in an organic solvent ("sol") with the rate law Rate $= k[(CH_3)_3CBr]$. We can write a two-step mechanism for the reaction:

$$(CH_3)_3CBr \longrightarrow (CH_3)_3C^+ + Br^-$$
$$(CH_3)_3C^+ + OH^- \longrightarrow (CH_3)_3COH$$

In this mechanism, the rate law for the first step is Rate $= k[(CH_3)_3CBr]$, the same as the experimental rate law. Because the reaction is zero order in OH^-, the hydroxide ion concentration does not affect the rate and we can assume that the first step is the slow step. As soon as $(CH_3)_3C^+$ is formed, it is immediately converted into the alcohol. Recall that elementary reactions following the rate-determining step do not contribute to the rate law derived from the mechanism.

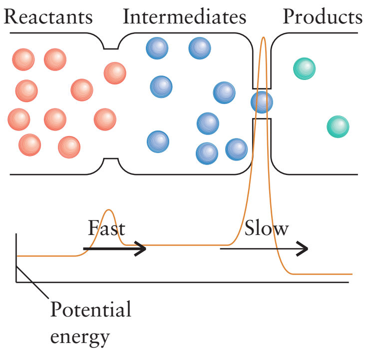

FIGURE 14.18 The rate-determining step in a reaction is an elementary reaction that governs the rate at which products are formed in a multistep series of reactions. The narrow neck representing the rate-determining step in the drawing is like a ferry that cannot handle the busy traffic on a highway. The superimposed "reaction profile" shows the energy requirements of each step. The step that requires the most energy is the slowest (see Section 14.12).

EXAMPLE 14.7 **Setting up an overall rate law from a proposed mechanism**

As remarked in Section 14.3, the following rate law has been determined for the decomposition of ozone in reaction E (Section 14.3), $2\,O_3(g) \longrightarrow 3\,O_2(g)$:

$$\text{Rate of decomposition of } O_3 = k\frac{[O_3]^2}{[O_2]}$$

The following mechanism has been proposed:

Step 1 $O_3 \rightleftarrows O_2 + O$

Step 2 $O + O_3 \rightleftarrows O_2 + O_2$

Measurements of the rates of the elementary forward reactions show that the slow step is the second step, the attack of O on O_3. The reverse reaction in the second step, $O_2 + O_2 \longrightarrow O + O_3$, is so slow that it can be ignored. Derive the rate law implied by the mechanism, and confirm that it matches the observed rate law.

A note on good practice: Be careful to distinguish the sign $\rightleftarrows$ (paired regular arrows), which signifies only that both forward and reverse reactions may occur, from the sign $\rightleftharpoons$ (paired single-barbed arrows), which signifies that the reactions are at equilibrium.

PLAN Construct the rate laws for the elementary reactions and combine them into the overall rate law for the decomposition of the reactant. If necessary, use the steady-state approximation for any intermediates and simplify it by using arguments based on rapid pre-equilibria and the existence of a rate-determining step.

SOLVE The rate laws for the elementary reactions are

Step 1	(forward) $O_3 \longrightarrow O_2 + O$	Rate of decomposition of $O_3 = k_1[O_3]$ (fast)
	(reverse) $O_2 + O \longrightarrow O_3$	Rate of formation of $O_3 = k_1'[O_2][O]$ (fast)
Step 2	(forward) $O + O_3 \longrightarrow O_2 + O_2$	Rate of consumption of $O_3 = k_2[O][O_3]$ (slow)
	(reverse) $O_2 + O_2 \longrightarrow O + O_3$	Rate of formation of $O_3 = k_2'[O_2]^2$ (very slow, ignore)

Write the rate law for the net rate of decomposition of O_3:

$$\text{Net rate of decomposition of } O_3 = k_1[O_3] - k_1'[O_2][O] + k_2[O][O_3]$$

To eliminate the O atom concentration from this expression, we consider the net rate of formation of O atoms and use the steady-state approximation to set that net rate equal to zero:

$$\text{Net rate of formation of O} = k_1[O_3] - k_1'[O_2][O] - k_2[O][O_3] = 0$$

This equation solves to

$$[O] = \frac{k_1[O_3]}{k_1'[O_2] + k_2[O_3]}$$

When we substitute this expression into the rate law for net rate of decomposition of ozone, we get

$$\text{Net rate of decomposition of } O_3 = k_1[O_3] - \frac{k_1k_1'[O_2][O_3]}{k_1'[O_2] + k_2[O_3]} + \frac{k_1k_2[O_3]^2}{k_1'[O_2] + k_2[O_3]}$$
$$= \frac{2k_1k_2[O_3]^2}{k_1'[O_2] + k_2[O_3]}$$

Thinking point: Verify for yourself that the three expressions in the first line do combine to give the final expression.

Because step 2 is slow relative to the fast pre-equilibrium, we can make the approximation $k_2[O][O_3] \ll k_1'[O_2][O]$, or equivalently by canceling the **[O]**, $k_2[O_3] \ll k_1'[O_2]$, and simplify this expression to

$$\text{Net rate of decomposition of } O_3 = \frac{2k_1k_2[O_3]^2}{k_1'[O_2]} = k\frac{[O_3]^2}{[O_2]}, \text{ with } k = 2k_1k_2/k_1'.$$

Evaluate This equation has exactly the same form as that of the observed rate law. Because the mechanism is consistent with both the balanced equation and the experimental rate law, we can consider it plausible.

Self-Test 14.11A Consider the following mechanism for the formation of a DNA double helix from its strands A and B:

$$A + B \rightleftharpoons \text{unstable helix (fast, } k_1 \text{ and } k_1' \text{ both large)}$$

$$\text{Unstable helix} \longrightarrow \text{stable double helix (slow, } k_2 \text{ very small)}$$

Derive the rate equation for the formation of the stable double helix and express the rate constant of the overall reaction in terms of the rate constants of the individual steps.

[***Answer:*** Rate $= k[A][B]$, $k = k_1k_2/k_1'$]

Self-Test 14.11B The proposed two-step mechanism for a reaction is $H_2A + B \longrightarrow BH^+ + HA^-$ and its reverse, both of which are fast, followed by $HA^- + B \longrightarrow BH^+ + A^{2-}$, which is slow. Find the rate law with HA^- treated as the intermediate and write the equation for the overall reaction.

The rate law of an elementary reaction is written from the equation for the reaction. A rate law is often derived from a proposed mechanism by imposing the steady-state approximation or assuming that there is a pre-equilibrium. To be plausible, a mechanism must be consistent with the experimental rate law.

14.9 Chain Reactions

In a **chain reaction,** a highly reactive intermediate reacts to produce another highly reactive intermediate, which reacts to produce another, and so on (Fig. 14.19). In many cases, the reaction intermediate—which in this context is called a **chain carrier**—is a radical, and the reaction is called a radical chain reaction. In a **radical chain reaction,** one radical reacts with a molecule to produce another radical, that radical goes on to attack another molecule to produce yet another radical, and so on. The ideas presented in the preceding sections apply to chain reactions, too, but they often result in very complex rate laws, which we will not derive.

The formation of HBr in the reaction

$$H_2(g) + Br_2(g) \longrightarrow 2\,HBr(g)$$

takes place by a chain reaction. The chain carriers are hydrogen atoms (H·) and bromine atoms (Br·). The first step in any chain reaction is **initiation,** the formation of chain carriers from a reactant. Often heat (denoted Δ) or light (denoted $h\nu$) is used to generate the chain carriers:

$$Br_2(g) \xrightarrow{\Delta \text{ or } h\nu} Br\cdot + Br\cdot$$

Once chain carriers have been formed, the chain can propagate in a reaction in which one carrier reacts with a reactant molecule to produce another carrier. The elementary reactions for the **propagation** of the chain are

$$Br\cdot + H_2 \longrightarrow HBr + H\cdot$$

$$H\cdot + Br_2 \longrightarrow HBr + Br\cdot$$

The chain carriers—radicals here—produced in these reactions can go on to attack other reactant molecules (H_2 and Br_2), thereby allowing the chain to continue. The elementary reaction that ends the chain, a process called **termination,** takes place when chain carriers combine to form products. Two examples of termination reactions are:

$$Br\cdot + Br\cdot \longrightarrow Br_2$$

$$H\cdot + Br\cdot \longrightarrow HBr$$

In some cases, a chain propagates explosively. Explosions can be expected when **chain branching** occurs—that is, when more than one chain carrier is formed in a propagation

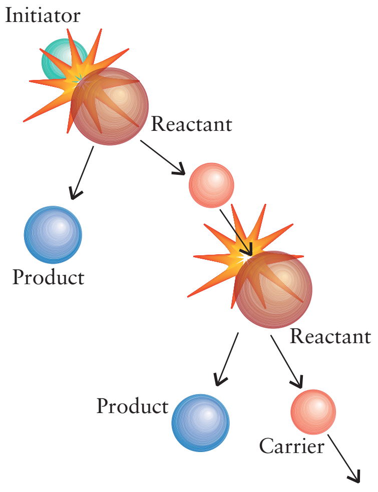

FIGURE 14.19 In a chain reaction, the product of one step in a reaction is a highly reactive reactant in a subsequent step, which in turn produces reactive species that can take part in other reaction steps.

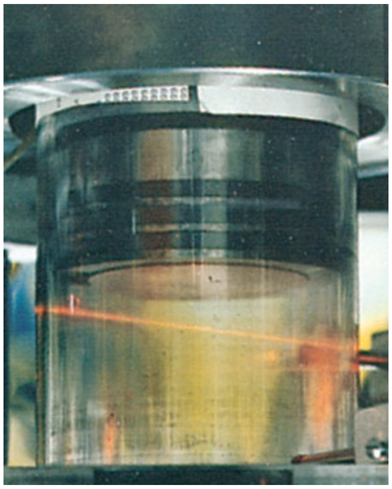

FIGURE 14.20 This flame front was caught during the fast combustion—almost a miniature explosion—that occurs inside an internal combustion engine every time a spark plug ignites the mixture of fuel and air.

step. Reactions that are explosively fast are often chain reactions. The characteristic pop that occurs when a mixture of hydrogen and oxygen is ignited is a consequence of chain branching. The two gases combine in a radical chain reaction in which the initiation step may be the formation of hydrogen atoms:

Initiation: $H_2 \xrightarrow{\Delta} H\cdot + H\cdot$

After the reaction has been initiated, two new radicals are formed when one hydrogen atom attacks an oxygen molecule:

Branching: $H\cdot + O_2 \longrightarrow HO\cdot + \cdot O\cdot$

The oxygen atom, with valence electron configuration $2s^2 2p_x^{\,2} 2p_y^{\,1} 2p_z^{\,1}$, has two electrons with unpaired spins (its Lewis symbol is $\cdot\ddot{\underset{..}{O}}\cdot$, which we abbreviate to $\cdot O\cdot$). Two radicals are also produced when the oxygen atom attacks a hydrogen molecule:

Branching: $\cdot O\cdot + H_2 \longrightarrow HO\cdot + H\cdot$

As a result of these branching processes, the chain produces an increasingly larger number of radicals that can take part in even more branching steps. The reaction rate increases rapidly, and an explosion typical of many combustion reactions may occur (Fig. 14.20).

Chain reactions begin with the initiation of a reactive intermediate that propagates the chain and concludes with termination when radicals combine. Branching chain reactions can be explosively fast.

14.10 Rates and Equilibrium

At equilibrium, the rates of the forward and reverse reactions are equal. Because the rates depend on rate constants and concentrations, we ought to be able to find a relation between rate constants for elementary reactions and the equilibrium constant for the overall reaction.

HOW DO WE DO THAT?

To deduce the relation between rate constants and equilibrium constants, we note that the equilibrium constant for a chemical reaction in solution that has the form $A + B \rightleftharpoons C + D$ is

$$K = \frac{[C][D]}{[A][B]}$$

Suppose that experiments show that both the forward reaction and the reverse reaction are elementary second-order reactions. Then we would write the following rate laws:

$$A + B \longrightarrow C + D \qquad \text{Rate} = k[A][B]$$
$$C + D \longrightarrow A + B \qquad \text{Rate} = k'[C][D]$$

At equilibrium, these two rates are equal, and so we can write

$$k[A][B] = k'[C][D]$$

It follows that, at equilibrium,

$$\frac{[C][D]}{[A][B]} = \frac{k}{k'}$$

Comparison of this expression with the expression for the equilibrium constant then shows that

$$K = \frac{k}{k'}$$

If the reaction involves gas-phase species and the rate law is expressed in terms of molar concentrations, then instead of K use K_c.

We have deduced that for a reaction $A + B \rightleftharpoons C + D$ that proceeds in a single bimolecular step in each direction,

$$K = \frac{k}{k'} \qquad (11)^*$$

That is, *the equilibrium constant for a reaction is equal to the ratio of the rate constants for the forward and reverse elementary reactions that contribute to the overall reaction*. We can now see from a consideration of kinetic data alone, with no knowledge of the Gibbs free energy of the reaction, when to expect a large equilibrium constant: $K \gg 1$ (and products are favored) when k for the forward direction is much larger than k' for the reverse direction. In this case, the fast forward reaction builds up a high concentration of products before reaching equilibrium (Fig. 14.21). In contrast, $K \ll 1$ (and reactants are favored) when k is much smaller than k'. Now the reverse reaction destroys the products rapidly, and so their concentrations are very low.

We derived the relation between the equilibrium constant and the rate constant for a single-step reaction. However, suppose that a reaction has a complex mechanism in which the elementary reactions have rate constants $k_1, k_2, \ldots$ and the reverse elementary reactions have rate constants $k_1', k_2', \ldots$. Then, by an argument similar to that for the single-step reaction, the overall equilibrium constant is related to the rate constants as follows:

$$K = \frac{k_1}{k_1'} \times \frac{k_2}{k_2'} \times \cdots \qquad (12)$$

The equilibrium constant for an elementary reaction is equal to the ratio of the forward and reverse rate constants of the reaction or, for multistep reactions, the ratio of the product of the forward rate constants to the product of the reverse rate constants.

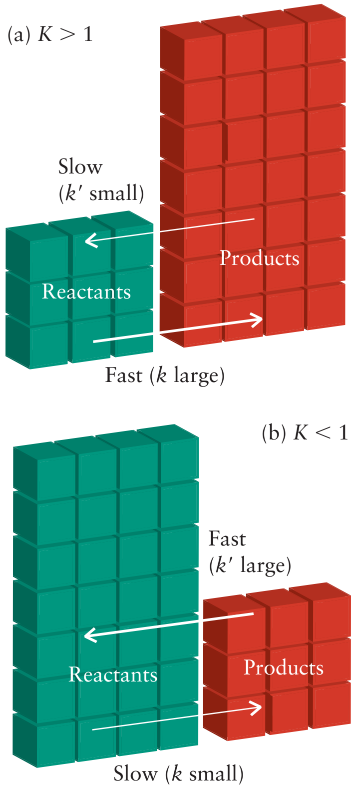

FIGURE 14.21 The equilibrium constant for a reaction is equal to the ratio of the rate constants for the forward and reverse reactions. (a) When the forward rate constant (k) is large compared to the reverse rate constant, the forward rate matches the reverse rate when the reaction has neared completion and the concentration of reactants is low. (b) Conversely, if the reverse rate constant (k') is larger than the forward rate constant, then the forward and reverse rates are equal when little reaction has taken place and the concentration of products is low.

MODELS OF REACTIONS

Rate laws and rate constants are windows into the molecular processes of chemical change. We have seen how rate laws reveal details of the mechanisms of reactions; here, we build models of the molecular processes that account for the values of the rate constants.

14.11 The Effect of Temperature

The rates of chemical reactions depend on temperature. The *qualitative* observation is that most reactions go faster as the temperature is raised (Fig. 14.22). An increase of 10°C from room temperature typically doubles the rate of reaction of organic species in solution. That is one reason why we cook foods: heating accelerates reactions that lead to the breakdown of cell walls and the decomposition of proteins. We refrigerate foods to slow down the natural chemical reactions that lead to their decomposition.

FIGURE 14.22 Reaction rates almost always increase with temperature. The beaker on the left contains magnesium in cold water and that on the right contains magnesium in hot water. An indicator has been added to show the formation of an alkaline solution as magnesium reacts.

How a reaction rate varies with temperature is summarized by the temperature dependence of the rate constant. In the late nineteenth century, the Swedish chemist Svante Arrhenius found that the plot of the logarithm of the rate constant ($\ln k$) against the inverse of the absolute temperature ($1/T$) is a straight line. In other words, he established that

$$\ln k = \text{intercept} + \text{slope} \times \frac{1}{T}$$

The intercept is denoted $\ln A$; and, for reasons that will become clear in Section 14.12, the slope is denoted $-E_a/R$, where R is the gas constant. With this notation, the empirical **Arrhenius equation** is

$$\ln k = \ln A - \frac{E_a}{RT} \qquad (13a)^*$$

An alternative form of this expression, which is obtained by taking antilogarithms of both sides, is

$$k = Ae^{-E_a/RT} \qquad (13b)^*$$

The use of the gas constant does not mean that the Arrhenius equation applies only to gases: it applies to a wide range of reactions in solution, too.

The two constants, A and E_a, are known as the **Arrhenius parameters** for the reaction and are found from experiment; A is called the **pre-exponential factor,** and E_a is the **activation energy.** Both A and E_a are nearly independent of temperature but have values that depend on the reaction being studied.

EXAMPLE 14.8 Measuring an activation energy

The rate constant for the second-order reaction between bromoethane and hydroxide ions in water, $C_2H_5Br(aq) + OH^-(aq) \longrightarrow C_2H_5OH(aq) + Br^-(aq)$, was measured at several temperatures, with the results shown here:

Temperature (°C)	25	30.	35	40.	45	50.
k (L·mol^{-1}·s^{-1})	8.8×10^{-5}	1.6×10^{-4}	2.8×10^{-4}	5.0×10^{-4}	8.5×10^{-4}	1.40×10^{-3}

Find the activation energy of the reaction.

Anticipate Activation energies of organic reactions are typically between 10 and 100 kJ·mol^{-1}, so we should expect a value within that range.

PLAN Activation energies are found from the Arrhenius equation (Eq. 13). We plot ln k against $1/T$, with T in kelvins. Because the slope is equal to $-E_a/R$, to find the activation energy we multiply the slope of the graph by $-R$ with $R = 8.3145$ J·K^{-1}·mol^{-1}. A spreadsheet, curve-fitting program, or the Living Graph "Variation of Rate Constant with Temperature" on the Web site for this book is very useful for this type of calculation.

SOLVE The table to use for drawing the graph is

Temperature (°C)	25	30.	35	40.	45	50.
T (K)	298	303	308	313	318	323
$1/T$ (K^{-1})	3.35×10^{-3}	3.30×10^{-3}	3.25×10^{-3}	3.19×10^{-3}	3.14×10^{-3}	3.10×10^{-3}
k (L·mol^{-1}·s^{-1})	8.8×10^{-5}	1.6×10^{-4}	2.8×10^{-4}	5.0×10^{-4}	8.5×10^{-4}	1.40×10^{-3}
ln k	−9.34	−8.74	−8.18	−7.60	−7.07	−6.57

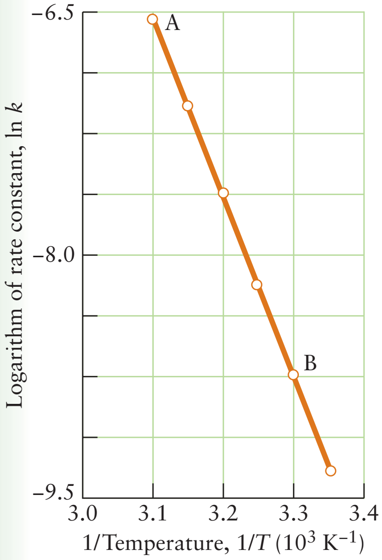

FIGURE 14.23 An Arrhenius plot is a graph of ln k against $1/T$. If, as here, the line is straight, then the reaction is said to show Arrhenius behavior in the temperature range studied. This plot has been constructed from the data in Example 14.8.

Living Graph 14.23

The points are plotted in Fig. 14.23.

We calculate the slope from any two points, such as those marked A and B:

$$\text{Slope} = \frac{(-8.74) - (-6.60)}{\{(3.30 \times 10^{-3}) - (3.10 \times 10^{-3})\}\text{K}^{-1}} = -\frac{2.14}{2.0 \times 10^{-4}\,\text{K}^{-1}}$$
$$= -1.07 \times 10^4\ \text{K}$$

Because the slope is equal to $-E_a/R$, from $E_a = -R \times$ slope,

$$E_a = -(8.3145\ \text{J·K}^{-1}\text{·mol}^{-1}) \times (-1.07 \times 10^4\ \text{K})$$
$$= 8.9 \times 10^4\ \text{J·mol}^{-1}$$

Evaluate The value we have calculated corresponds to 89 kJ·mol^{-1}, which is in line with the range we anticipated.

Self-Test 14.12A The rate constant for the second-order gas-phase reaction $HO(g) + H_2(g) \longrightarrow H_2O(g) + H(g)$ varies with the temperature as shown here:

Temperature (°C)	100.	200.	300.	400.
k (L·mol^{-1}·s^{-1})	1.1×10^{-9}	1.8×10^{-8}	1.2×10^{-7}	4.4×10^{-7}

Determine the activation energy.

[***Answer:*** 42 kJ·mol^{-1}]

TABLE 14.4 **Arrhenius Parameters**

Reaction	A	E_a ($kJ\cdot mol^{-1}$)
First order, gas phase		
cyclopropane $\longrightarrow$ propene	$1.6 \times 10^{15}\ s^{-1}$	272
$CH_3NC \longrightarrow CH_3CN$	$4.0 \times 10^{13}\ s^{-1}$	160
$C_2H_6 \longrightarrow 2\ CH_3$	$2.5 \times 10^{17}\ s^{-1}$	384
$N_2O \longrightarrow N_2 + O$	$8.0 \times 10^{11}\ s^{-1}$	250
$2\ N_2O_5 \longrightarrow 4\ NO_2 + O_2$	$4.0 \times 10^{13}\ s^{-1}$	103
Second order, gas phase		
$O + N_2 \longrightarrow NO + N$	$1 \times 10^{11}\ L\cdot mol^{-1}\cdot s^{-1}$	315
$OH + H_2 \longrightarrow H_2O + H$	$8 \times 10^{10}\ L\cdot mol^{-1}\cdot s^{-1}$	42
$2\ CH_3 \longrightarrow C_2H_6$	$2 \times 10^{10}\ L\cdot mol^{-1}\cdot s^{-1}$	0
Second order, in aqueous solution		
$C_2H_5Br + OH^- \longrightarrow C_2H_5OH + Br^-$	$4.3 \times 10^{11}\ L\cdot mol^{-1}\cdot s^{-1}$	90
$CO_2 + OH^- \longrightarrow HCO_3^-$	$1.5 \times 10^{10}\ L\cdot mol^{-1}\cdot s^{-1}$	38
$C_{12}H_{22}O_{11} + H_2O \longrightarrow 2\ C_6H_{12}O_6$	$1.5 \times 10^{15}\ L\cdot mol^{-1}\cdot s^{-1}$	108

Self-Test 14.12B The rate of a reaction increased from 3.00 $mol\cdot L^{-1}\cdot s^{-1}$ to 4.35 $mol\cdot L^{-1}\cdot s^{-1}$ when the temperature was raised from 18°C to 30.°C. What is the activation energy of the reaction?

Reactions that give a straight line when $\ln k$ is plotted against $1/T$ are said to show **Arrhenius behavior.** A wide range of reactions show Arrhenius behavior. Even tropical fireflies flash more quickly on hot nights than on cold nights, and their rate of flashing is Arrhenius-like over a small range of temperatures. We can conclude that the biochemical reactions responsible for the flashing have rate constants that increase with temperature in accord with Eq. 13. Some Arrhenius parameters are listed in Table 14.4.

Because the slope of an Arrhenius plot is proportional to E_a, it follows that *the higher the activation energy, the stronger the temperature dependence of the rate constant*. Reactions with low activation energies (about 10 $kJ\cdot mol^{-1}$, with not very steep Arrhenius plots) have rates that increase only slightly with temperature. Reactions with high activation energies (above approximately 60 $kJ\cdot mol^{-1}$, with steep Arrhenius plots) have rates that depend strongly on the temperature (Fig. 14.24).

The Arrhenius equation is used to predict the value of a rate constant at one temperature from its value at another temperature.

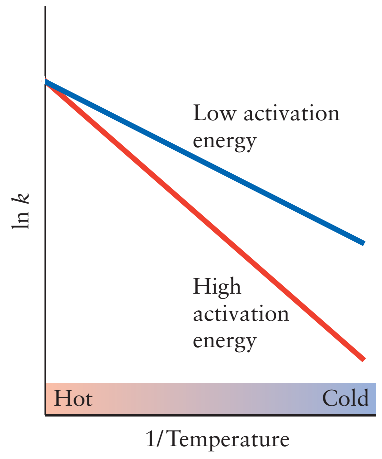

FIGURE 14.24 The dependence of the rate constant on temperature for two reactions with different activation energies. The higher the activation energy, the more strongly the rate constant depends on temperature.

HOW DO WE DO THAT?

The Arrhenius equations for the two temperatures, which we call T and T', when the rate constant for the reaction has the values k and k', respectively, are

$$\text{At temperature } T'\text{: } \ln k' = \ln A - \frac{E_a}{RT'}$$

$$\text{At temperature } T\text{: } \ln k = \ln A - \frac{E_a}{RT}$$

We eliminate $\ln A$ by subtracting the second equation from the first:

$$\ln k' - \ln k = -\frac{E_a}{RT'} + \frac{E_a}{RT}$$

The expression that we have derived can easily be rearranged into

$$\ln\frac{k'}{k} = \frac{E_a}{R}\left(\frac{1}{T} - \frac{1}{T'}\right) \quad (14)$$

By examining this expression we can draw the following conclusions about the temperature dependence of the rate constant:

> When $T' > T$, the right-hand side is positive, so $\ln (k'/k)$ is positive, which means that $k' > k$. That is, the rate constant increases with temperature.
>
> For fixed values of T and T', $\ln (k'/k)$ is large when E_a is large; so the increase in rate constant is large when the activation is large.

Both conclusions are in line with our interpretation of the Arrhenius equation itself.

EXAMPLE 14.9 Using the activation energy to predict a rate constant

The hydrolysis of sucrose is a part of the digestive process. To investigate how strongly the rate depends on our body temperature, calculate the rate constant for the hydrolysis of sucrose at 35.0°C, given that $k = 1.0\ \text{mL·mol}^{-1}\text{·s}^{-1}$ at 37.0°C (normal body temperature) and that the activation energy of the reaction is $108\ \text{kJ·mol}^{-1}$.

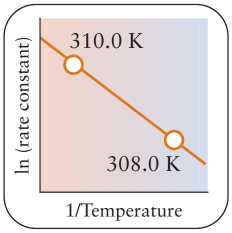
Anticipate We should expect a lower rate constant at the lower temperature.

PLAN Use Eq. 14 with $T = 310.0$ K and $T' = 308.0$ K and express R in kilojoules per kelvin per mole to cancel the units of E_a.

SOLVE

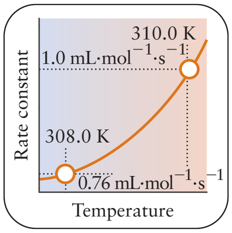
From $\ln (k'/k) = (E_a/R)(1/T - 1/T')$,

$$\ln \frac{k'}{k} = \frac{108\ \text{kJ·mol}^{-1}}{8.3145 \times 10^{-3}\ \text{kJ·K}^{-1}\text{·mol}^{-1}} \times \left(\frac{1}{310.0\ \text{K}} - \frac{1}{308.0\ \text{K}}\right) = -0.27$$



From $x = e^{\ln x}$,

$$\frac{k'}{k} = e^{-0.27}$$



Finally, because $k = 1.0\ \text{mL·mol}^{-1}\text{·s}^{-1}$,

$$k' = (1.0\ \text{mL·mol}^{-1}\text{·s}^{-1}) \times e^{-0.27} = 0.76\ \text{mL·mol}^{-1}\text{·s}^{-1} \text{ at } 35°\text{C}.$$

Evaluate As expected, the rate constant at the lower temperature is lower. The high activation energy of the reaction means that its rate is very sensitive to temperature.

A note on good practice: We have evaluated the exponent (−0.27) in this example to avoid writing a cumbersome expression for k'/k; our recommended good practice of doing the numerical calculation in one final step does not, in this instance, change the final result (to 2sf).

Self-Test 14.13A The rate constant for the second-order reaction between CH_3CH_2Br and OH^- in water is $0.28\ \text{mL·mol}^{-1}\text{·s}^{-1}$ at 35.0°C. What is the value of the rate constant at 50.0°C? See Table 14.4 for data.

[***Answer:*** $1.4\ \text{mL·mol}^{-1}\text{·s}^{-1}$]

Self-Test 14.13B The rate constant for the first-order isomerization of cyclopropane, C_3H_6, to propene, $CH_3CH{=}CH_2$, is $6.7 \times 10^{-4}\ \text{s}^{-1}$ at 500.°C. What is its value at 300.°C? See Table 14.4 for data.

An Arrhenius plot of ln k against 1/T is used to determine the Arrhenius parameters of a reaction; a large activation energy signifies a high sensitivity of the rate constant to changes in temperature.

14.12 Collision Theory

We are now ready to build a model of how chemical reactions take place at the molecular level. Specifically, our model must account for the temperature dependence of rate constants, as expressed by the Arrhenius equation; it should also reveal the significance of the Arrhenius parameters A and E_a. Reactions in the gas phase are conceptually simpler than those in solution, and so we begin with them.

First, we assume that a reaction can take place only if reactants meet. In a gas that meeting is a collision, and so the model that we are building is called the **collision theory** of reactions. In this model, we suppose that molecules behave like defective billiard balls: they bounce apart if they collide at low speed, but they might smash into pieces when the impact is really energetic. If two molecules collide with less than a certain kinetic energy, they simply bounce apart. If they meet with more than that kinetic energy, reactant bonds can break and new bonds can form, resulting in products (Fig. 14.25). We denote the minimum kinetic energy needed for reaction by E_{min}.

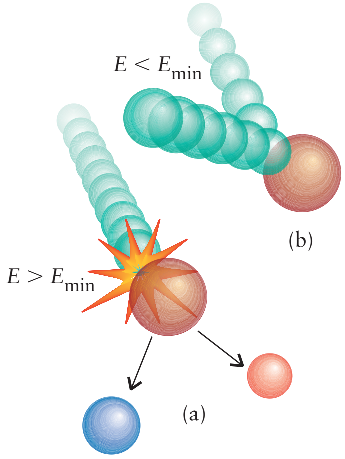


FIGURE 14.25 (a) In the collision theory of chemical reactions, reaction may take place only when two molecules collide with a kinetic energy at least equal to a minimum value, E_{min} (which later we identify with the activation energy). (b) Otherwise, they simply bounce apart.

To set up a quantitative theory based on this qualitative picture, we need to know the rate at which molecules collide and the fraction of those collisions that have at least the energy E_{min} required for reaction to occur. The collision frequency (the number of collisions per second) between A and B molecules in a gas at a temperature T can be calculated from the kinetic model of a gas (Section 4.10):

$$\text{Collision frequency} = \sigma \bar{v}_{rel} N_A^2[\text{A}][\text{B}] \qquad (15)$$

in which N_A is Avogadro's constant and σ (sigma) is the **collision cross section,** the area that a molecule presents as a target during a collision. The bigger the collision cross section, the greater the collision frequency, because big molecules are easier targets than small molecules. The quantity $\bar{v}_{rel}$ is the **mean relative speed,** the mean speed at which the molecules approach each other in a gas. The mean relative speed is calculated by multiplying each possible speed by the fraction of molecules that have that speed and then adding all the products together. When the temperature is T and the molar masses are M_A and M_B, this mean relative speed is

$$\bar{v}_{rel} = \left(\frac{8RT}{\pi\mu}\right)^{1/2} \qquad \mu = \frac{M_A M_B}{M_A + M_B} \qquad (16)^*$$

The collision frequency is greater the higher the relative speeds of the molecules, and therefore the higher the temperature.

Although the mean relative speed of the molecules increases with temperature, and the collision frequency therefore increases as well, Eq. 16 shows that the mean relative speed increases only as the square root of the temperature. This dependence is far too weak to account for observations. If we used Eq. 16 to predict the temperature dependence of reaction rates, we would conclude that an increase in temperature of 10°C at about room temperature (from 273 K to 283 K) increases the collision frequency by a factor of only 1.02, whereas experiments show that many reaction rates double over that range. Another factor must be affecting the rate.

To find this factor, we need a measure of the fraction of molecules that collide with a kinetic energy equal to or greater than a certain minimum energy, E_{min}, because only these energetic collisions can result in reaction. Because kinetic energy is proportional to the square of the speed, this fraction can be obtained from the Maxwell distribution of speeds (Section 4.11). Figure 14.26 shows the kind of result we can expect. As indicated for a specific reaction by the shaded area under the blue curve, at a low temperature very few molecules have enough kinetic energy to react. At higher temperatures, a much larger fraction of molecules can react, as represented by the shaded area under the red curve. We need to bring this fraction into our equations.

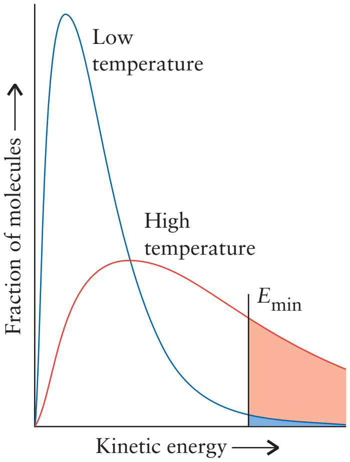

FIGURE 14.26 The fraction of molecules that collide with a kinetic energy that is at least equal to a certain minimum value, E_{min} (which later we show to be the activation energy, E_a), is given by the shaded areas under each curve. Note that this fraction increases rapidly as the temperature is raised.

HOW DO WE DO THAT?

To find how the fraction of molecules that collide with at least an energy E_{min} affects the rate of an elementary reaction, we need to know that, at a temperature T, the fraction of collisions with at least the energy E_{min} is equal to $e^{-E_{min}/RT}$, where R is the gas constant. That result comes from an expression known as the *Boltzmann distribution*, which we do not derive here. The rate of reaction is the product of this factor and the collision frequency:

$$\begin{aligned}\text{Rate of reaction} &= \text{collision frequency} \times \text{fraction with sufficient energy}\\ &= \sigma\bar{v}_{rel}N_A{}^2[\text{A}][\text{B}] \times e^{-E_{min}/RT}\end{aligned}$$

The rate law of an elementary reaction that depends on collisions of A with B is Rate = k[A][B], where k is the rate constant. We can therefore identify the expression for the rate constant as

$$k = \frac{\text{rate of reaction}}{[\text{A}][\text{B}]} = \frac{\sigma\bar{v}_{rel}N_A{}^2[\text{A}][\text{B}] \times e^{-E_{min}R/T}}{[\text{A}][\text{B}]} = \sigma\bar{v}_{rel}N_A{}^2 e^{-E_{min}/RT}$$

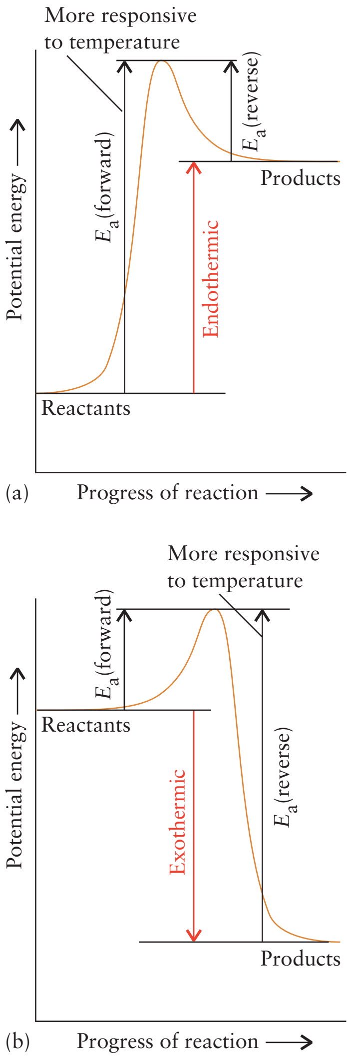

FIGURE 14.27 (a) The activation energy for an endothermic reaction is larger in the forward direction than in the reverse, and so the rate of the forward reaction is more sensitive to temperature and the equilibrium shifts toward products as the temperature is raised. (b) The opposite is true for an exothermic reaction, in which case the reverse reaction is more sensitive to temperature and the equilibrium shifts toward reactants as the temperature is raised.

We have deduced that, according to collision theory, the rate constant is

$$k = \sigma\bar{v}_{rel}N_A{}^2 e^{-E_{min}/RT} \qquad (17)$$

This exponential temperature dependence for k is much stronger than the weak temperature dependence of the collision frequency itself. By comparing Eq. 17 with Eq. 13b, we can identify the term $\sigma\bar{v}_{rel}N_A{}^2$ as the pre-exponential factor, A, and E_{min} as the activation energy, E_a. That is, we can conclude that

- A is a measure of the rate at which molecules collide.
- The activation energy, E_a, is the minimum kinetic energy required for a collision to result in reaction.

We now understand why some thermodynamically spontaneous reactions do not take place at a measurable rate: they have such high activation energies that hardly any of the collisions between reactants result in reaction. A mixture of hydrogen and oxygen can survive for years: the activation energy for the production of radicals is very high, and no radicals are formed until a spark or flame is brought into contact with the mixture.

The dependence of the rate constant on temperature, its sensitivity to the activation energy, and the fact that the equilibrium constant is equal to the ratio of the forward and reverse rate constants (Eq. 11, $K = k/k'$), jointly provide a kinetic explanation for the temperature dependence of the equilibrium constant. To see what is involved, we need to introduce the concept of a diagram called a **reaction profile** which is used to represent the energy changes that occur during a reaction (Fig. 14.27). Then, with that diagram in mind and remembering that a high activation energy indicates a high sensitivity of the rate constant to temperature:

- If the reaction is endothermic in the forward direction, the activation energy is higher for the forward direction than for the reverse direction. The higher activation energy means that the rate constant of the forward reaction depends more strongly on temperature than does the rate constant of the reverse reaction. Therefore, when the temperature is raised, the rate constant for the forward reaction increases more than that of the reverse reaction. As a result, $K = k/k'$ will increase and the products will become more favored.
- If the reaction is exothermic in the forward direction, the activation energy is lower for the forward direction than for the reverse direction. The lower activation energy means that the rate constant of the forward reaction depends less strongly on temperature than does the rate constant of the reverse reaction. Therefore, when the temperature is raised, the rate constant for the forward reaction increases less than that of the reverse reaction. As a result, $K = k/k'$ will decrease and the products will become less favored.

Both conclusions are in accord with Le Chatelier's principle.

Now that we have a model, we must check its consistency with various experiments. Sometimes such inconsistencies result in the complete rejection of a model. More often, they indicate that we need to refine the model. In the present case, the results of careful

experiments show that the collision model of reactions is not complete, because the experimental rate constant is normally smaller than predicted by collision theory. We can improve the model by realizing that the relative *orientation* of the molecules when they collide also might matter. For example, the results of experiments of the kind described in Box 14.2 have shown that, in the gas-phase reaction of chlorine atoms with HI molecules, $HI + Cl \longrightarrow HCl + I$, the Cl atom reacts with the HI molecule only if it approaches from a favorable direction (Fig. 14.28). A dependence on relative orientation is called the **steric requirement** of the reaction. It is normally taken into account by introducing an empirical factor, P, called the **steric factor,** and changing Eq. 17 to

$$k = \overbrace{P}^{\text{Steric requirement}} \times \overbrace{\sigma \bar{v}_{rel} N_A^2}^{\text{Collision rate}} \times \overbrace{e^{-E_{min}/RT}}^{\text{Energy requirement}} \quad (18)^*$$

BOX 14.2 HOW DO WE KNOW . . . WHAT HAPPENS DURING A MOLECULAR COLLISION?

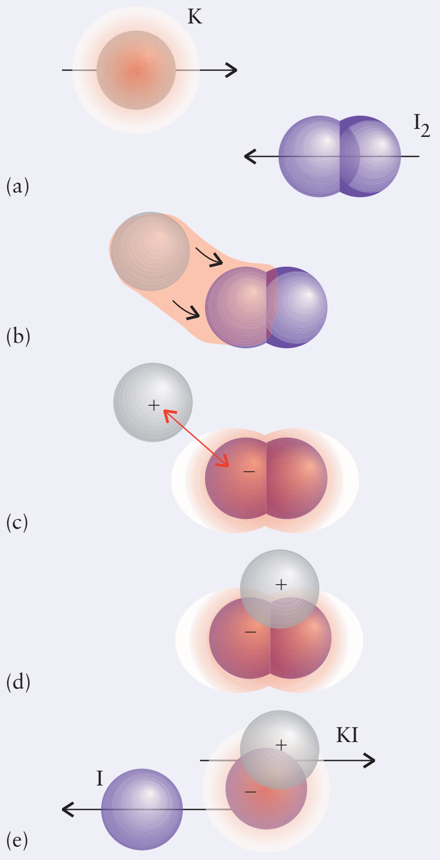
When molecules collide, old bonds give way to new ones and atoms in one molecule become part of another. Is there any way of finding out *experimentally* what is happening at this climactic stage of a reaction?

Molecular beams provide the answer. We first met molecular beams in Box 4.1, where we saw how a velocity selector is constructed. A molecular beam consists of a stream of molecules moving in the same direction with the same speed. A beam may be directed at a gaseous sample or into the path of a second beam, consisting of molecules of a second reactant. The molecules may react when the beams collide; the experimenters can then detect the products of the collision and the direction at which the products emerge from the collision. They also use spectroscopic techniques to determine the vibrational and rotational excitation of the products.

By repeating the experiment with molecules having different speeds and different states of rotational or vibrational excitation, chemists can learn more about the collision itself. For example, experimenters have found that, in the reaction between a Cl atom and an HI molecule, the best direction of attack is within a cone of half-angle 30° surrounding the H atom (see Fig. 14.28).

In a "sticky" collision, the reactant molecules orbit around each other for one revolution or more. As a result, the product molecules emerge in random directions because any "memory" of the approach direction is lost. However, a rotation takes time—about 1 ps. If the reaction is over before that, the product molecules will emerge in a specific direction that depends on the direction of the collision. In the collision of K and I_2, for example, most of the products are thrown off in the forward direction. This observation is consistent with the "harpoon mechanism" that had been proposed for this reaction. In this mechanism, an electron flips across from the K atom to the I_2 molecule when they are quite far apart, and the resulting K^+ ion extracts one of the atoms of the negatively charged I_2^- ion. We can think of the electron as a harpoon, the electrostatic attraction as the line attached to the harpoon, and I_2 as a whale. Because the crucial "harpooning" occurs at large distances and there is no actual collision, the products are thrown off in approximately the same direction as the reactants were traveling.

The reaction between a K atom and a CH_3I molecule takes place by a different mechanism. A collision leads to reaction only if the two reactants approach each other very closely. In this mechanism, the K atom effectively bumps into a brick wall, and the KI product bounces out in the backward direction.



In the harpoon mechanism for the reaction between potassium and iodine to form potassium iodide, as a K atom approaches an I_2 molecule (a), an electron passes from the K atom to the I_2 molecule (b). The charge difference now tethers the two ions together (c and d) until an I^- ion separates and leaves with the K^+ ion (e).

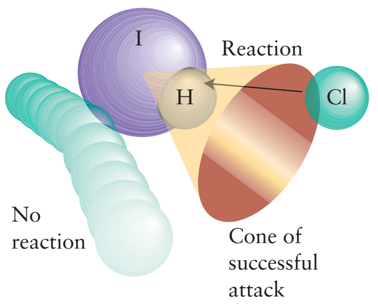


FIGURE 14.28 Whether a reaction takes place when two species collide in the gas phase depends on their relative orientations. In the reaction between a Cl atom and an HI molecule, for example, only those collisions in which the Cl atom approaches the HI molecule from a direction that lies inside the cone indicated here lead to reaction, even though the energy of collisions in other relative orientations may exceed the activation energy.

TABLE 14.5 The Steric Factor, *P*

Reaction	*P*
$NOCl + NOCl \longrightarrow NO + NO + Cl_2$	0.16
$NO_2 + NO_2 \longrightarrow NO + NO + O_2$	5.0×10^{-2}
$ClO + ClO \longrightarrow Cl_2 + O_2$	2.5×10^{-3}
$H_2 + C_2H_4 \longrightarrow C_2H_6$	1.7×10^{-6}

Table 14.5 lists some values of P. All the values shown are less than 1 because the steric requirement reduces the probability of reaction. For collisions between complex species, the steric requirement may be severe, and P is very small. In such cases, the reaction rate is considerably less than the rate at which high-energy collisions occur.

Thinking point: Why might the harpoon mechanism described in Box 14.2 result in a value of P greater than 1?

According to the collision theory of gas-phase reactions, a reaction takes place only if the reactant molecules collide with a kinetic energy of at least the activation energy, and they do so in the correct relative orientation.

14.13 Transition State Theory

Although collision theory applies to gas-phase reactions, we can extend some of its concepts to explain why the Arrhenius equation also applies to reactions in solution. There, molecules do not speed through space and collide, but jostle through the solvent and stay in one another's vicinity for relatively long periods. The more general theory that accounts both for this behavior and for reactions in gases is called **transition state theory** (which is also known as *activated complex theory*). This theory improves on collision theory by suggesting a way of calculating the rate constant even when steric requirements are significant.

In transition state theory we imagine two molecules approaching each other and being distorted as they come close enough to affect each other. In the gas phase, that meeting and distortion are equivalent to the "collision" of collision theory. In solution, the approach is a jostling zigzag walk among solvent molecules, and the distortion might not take place until after the two reactant molecules have met and received a particularly vigorous kick from the solvent molecules around them (Fig. 14.29). In either case, the collision or the kick does not immediately tear the molecules apart. Instead, the encounter results in the formation of an **activated complex,** an arrangement of the two molecules that can either go on to form products or fall apart again into the unchanged reactants. An activated complex is also commonly called a **transition state.**

In the activated complex, the original bonds have lengthened and weakened, and the new bonds are only partly formed. For example, in the proton transfer reaction between the weak acid HCN and water, the activated complex can be pictured as consisting of an HCN molecule with its hydrogen atom in the process of forming a hydrogen bond to the oxygen atom of a water molecule and poised midway between the two molecules. At this point, the hydrogen atom could re-form HCN or leave as the product H_3O^+.

In transition state theory, the activation energy is a measure of the energy of the activated complex relative to that of the reactants. The reaction profile in Fig. 14.30 shows how the energy of the reaction mixture changes as the reactants meet, form the activated complex, and then go on to form products. A reaction profile shows the potential energy of the reactants and products, their total energy arising from their relative location, not their relative speed. Now consider what happens when reactants approach each other with a certain kinetic energy. As the reactants approach, they lose kinetic energy as they "climb" up the left side of the barrier (that is, as their potential energies increase due to the repulsion resulting from their closer approach and the distortions of their bonds). If

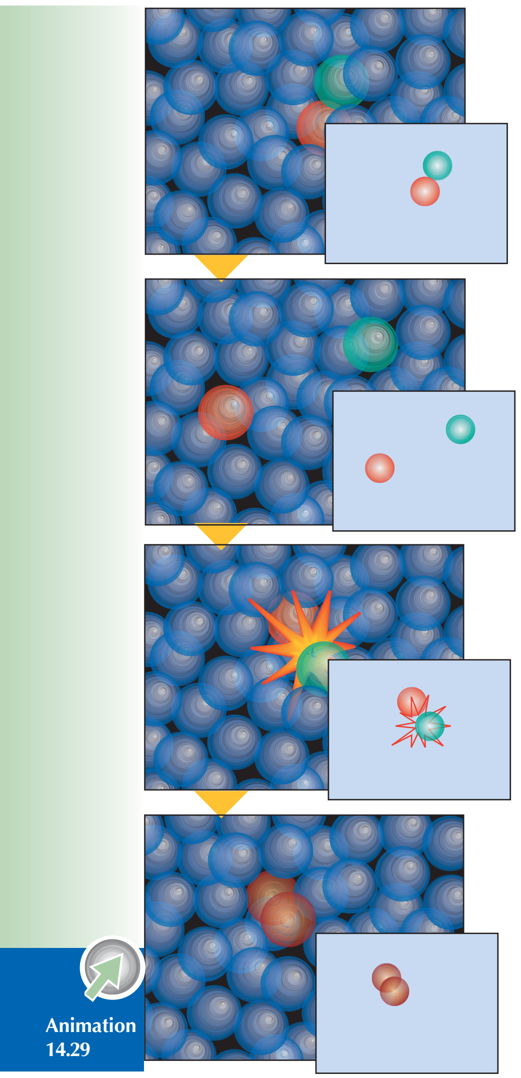

FIGURE 14.29 This sequence of images shows the reactant molecules in solution as they meet, then either move apart, or acquire enough energy by impacts from the solvent molecules to form an activated complex, which may go on to form products.

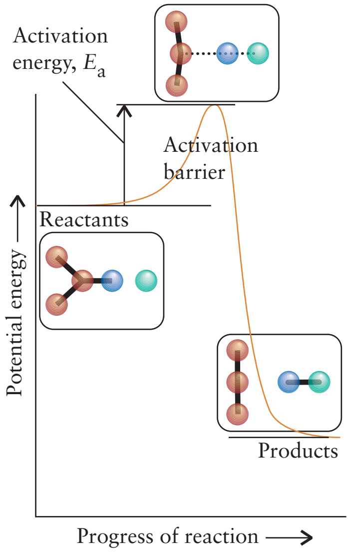
FIGURE 14.30 A reaction profile for an exothermic reaction. In the activated complex theory of reaction rates, it is supposed that the potential energy (the energy due to position) increases as the reactant molecules approach each other and reaches a maximum as they form an activated complex. It then decreases as the atoms rearrange into the bonding pattern characteristic of the products and these products separate. Only molecules with enough energy can cross the activation barrier and react to form products.



the initial kinetic energy of the reactants is less than E_a, they cannot climb to the top of the potential barrier, and they "roll" back down on the left and separate again. If their initial kinetic energy is at least E_a, they can form the activated complex, pass over the top of the barrier, and roll down the other side, where they separate as products.

A **potential energy surface** can help us visualize the energy changes in the course of a reaction as a function of the locations of the atoms. In this three-dimensional plot, the z-axis is a measure of the total potential energy of the reactants and products and the x- and y-axes represent interatomic distances. For example, the plot in Fig. 14.31 shows the potential energy changes that occur in the attack of a bromine atom on a hydrogen molecule and the reverse process, the attack of a hydrogen atom on an HBr molecule:

$$H_2 + Br\cdot \longrightarrow HBr + H\cdot$$
$$HBr + H\cdot \longrightarrow H_2 + Br\cdot$$

The low-energy locations corresponding to the reactants and products are separated by a barrier over which there is a path of minimum potential energy and which the kinetic energy of the approaching molecules must overcome. The actual path of the encounter depends on the total energies of the particles, but we can gain insight into the reaction process by examining potential energy changes alone. For example, suppose the H—H bond remained the same length as the Br atom approached. That would take the system to point A, a state of very high potential energy. In fact, at normal temperatures, the colliding species might not have enough kinetic energy to reach this point. The path that involves lowest potential energy is the one up the foot of the valley, over the "saddle point" (the saddle-shaped region) at the top of the pass, and down the foot of the valley on the other side of the pass. Only the lowest-energy path is available: the H—H bond must lengthen as the new H—Br bond begins to form.

As in collision theory, the rate of the reaction depends on the rate at which reactants can climb to the top of the barrier and form the activated complex. The resulting expression for the rate constant is very similar to the one given in Eq. 15, and so this more general theory also accounts for the form of the Arrhenius equation and the observed dependence of the reaction rate on temperature.

In transition state theory, a reaction takes place only if two molecules acquire enough energy, perhaps from the surrounding solvent, to form an activated complex and cross an energy barrier.

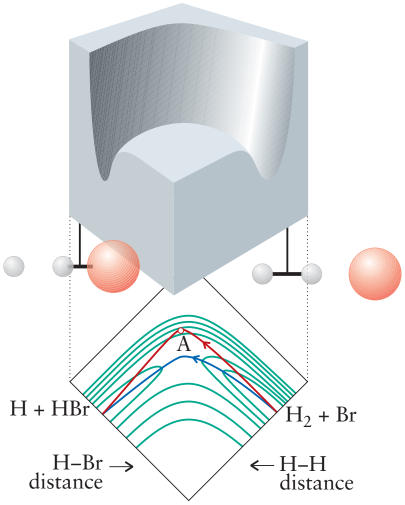


FIGURE 14.31 The contours of a potential energy surface for the reaction between a hydrogen molecule and a bromine atom (on the right). The atoms have been constrained to approach and depart in a straight line. The path of lowest potential energy (blue) is up one valley, across the pass—the saddle-shaped high point—and down the floor of the other valley to the products (on the left). The path shown in red would take the atoms to very high potential energies.

ACCELERATING REACTIONS

We have seen that the rates of many reactions increase if we increase the concentration of reactants or the temperature. Similarly, the rate of a heterogeneous reaction can be increased by increasing the surface area of a reactant (Fig. 14.32). But suppose we want to increase the rate for a given concentration or surface area without raising the temperature? These sections describe an alternative.

14.14 Catalysis

One way to increase the rate of a reaction is to use a **catalyst,** a substance that increases the rate without being consumed in the reaction (Fig. 14.33). The name comes from the Greek words meaning "breaking down by coming together." In many cases, only a small amount of catalyst is necessary, because it acts over and over again. This is why small amounts of chlorofluorocarbons can have such a devastating effect on the ozone layer in the stratosphere—they break down into radicals that catalyze the destruction of ozone (Box 14.3).

A catalyst speeds up a reaction by providing an alternative pathway—a different reaction mechanism—between reactants and products. This new pathway has a lower

FIGURE 14.32 Iron pots and pans can be heated in a flame without catching fire. However, a powder of finely divided iron filings oxidizes rapidly in air to form Fe_2O_3, because the powder presents a much greater surface area for reaction.

Lab Video 14.32

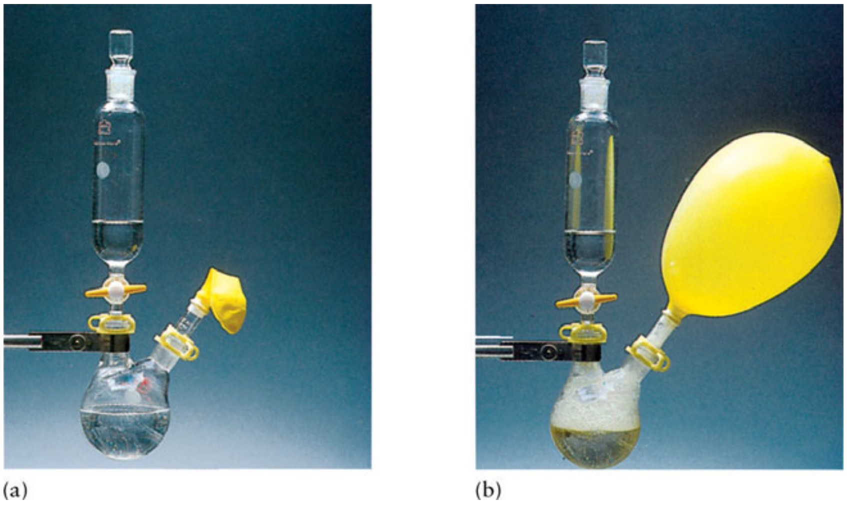

FIGURE 14.33 A small amount of catalyst—in this case, potassium iodide in aqueous solution—can accelerate the decomposition of hydrogen peroxide to water and oxygen. (a) The slow inflation of the balloon when no catalyst is present. (b) Its rapid inflation when a catalyst is present.

The Chinese characters for catalyst, which translate as "marriage broker," capture the sense quite well.

activation energy than the original pathway (Fig. 14.34). At the same temperature, a greater fraction of reactant molecules can cross the lower barrier of the catalyzed path and turn into products than when no catalyst is present. Although the reaction takes place more quickly, a catalyst has no effect on the equilibrium composition. Both forward and reverse reactions are accelerated on the catalyzed path, leaving the equilibrium constant unchanged.

In some cases the original reaction with a slow rate-determining step may continue in parallel with the catalyzed reaction. However, the rate is determined by the faster path, which governs the overall rate of formation of products. A very slow elementary reaction does not control the rate if it can be sidestepped by a faster one on an alternative (usually catalyzed) path (Fig. 14.35).

A **homogeneous catalyst** is a catalyst that is in the same phase as the reactants. For reactants that are gases, a homogeneous catalyst is also a gas. If the reactants are in a liquid solution, a homogeneous catalyst is dissolved in the solution. Dissolved bromine is a homogeneous liquid-phase catalyst for the decomposition of aqueous hydrogen peroxide:

$$2\,H_2O_2(aq) \longrightarrow 2\,H_2O(l) + O_2(g)$$

In the absence of bromine or another catalyst, a solution of hydrogen peroxide can be stored for a long time at room temperature; however, bubbles of oxygen form as soon as a drop of bromine is added. Bromine's role in this reaction is believed to be its reduction to Br^- in one step, followed by oxidation back to Br_2 in a second step:

$$Br_2(aq) + H_2O_2(aq) \longrightarrow 2\,Br^-(aq) + 2\,H^+(aq) + O_2(g)$$
$$2\,Br^-(aq) + H_2O_2(aq) + 2\,H^+(aq) \longrightarrow Br_2(aq) + 2\,H_2O(l)$$

When we add the two steps, both the catalyst, Br_2, and the intermediate, Br^-, cancel, leaving the overall equation as $2\,H_2O_2(aq) \longrightarrow 2\,H_2O(l) + O_2(g)$. Hence, although Br_2 molecules have participated in the reaction, they are not consumed and can be used over and over again.

Although a catalyst does not appear in the balanced equation for a reaction, the concentration of a homogeneous catalyst does appear in the rate law. For example, the reaction between the triiodide ion and the azide ion is very slow unless a catalyst such as carbon disulfide is present:

$$I_3^-(aq) + 2\,N_3^-(aq) \xrightarrow{CS_2} 3\,I^-(aq) + 3\,N_2(g)$$

The mechanism for the reaction has two steps:

Step 1 Carbon disulfide forms a reactive intermediate, a complex with azide ions:

$$CS_2 + N_3^- \longrightarrow S_2CN_3^- \text{ (slow)}$$

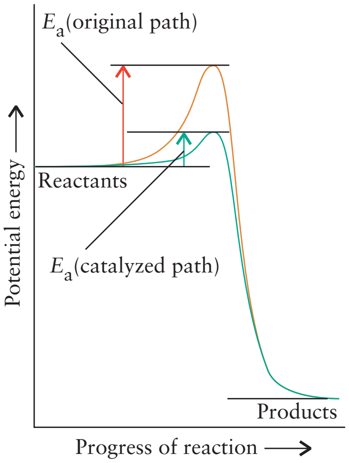

FIGURE 14.34 A catalyst provides a new reaction pathway with a lower activation energy, thereby allowing more reactant molecules to cross the barrier and form products.

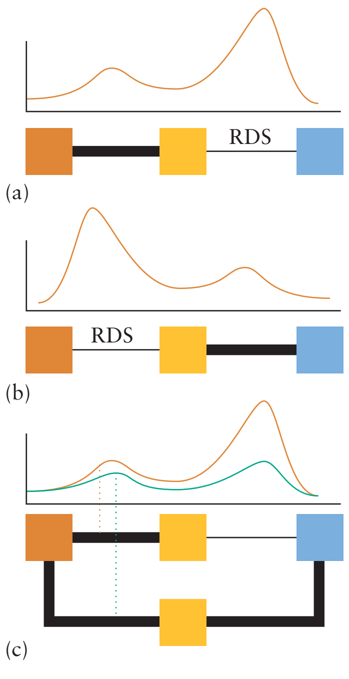

FIGURE 14.35 (a) If the rate-determining step (RDS) is the second step, the rate law for that step determines the rate law for the overall reaction. The orange curve shows the "reaction profile" for such a mechanism, with a lot of energy required for the slow step. The rate law derived from such a mechanism takes into account steps that precede the RDS. (b) If the rate-determining step is the first step, the rate law for that step must match the rate law for the overall reaction. Later steps do not affect the rate or the rate law. (c) If two routes to the product are possible, the faster one (in this case, the lower one) determines the rate of the reaction; in the mechanism forming the upper route, the slow step (thinner line) is not an RDS.

Step 2 The complex then reacts rapidly with triiodide ion in a series of fast elementary reactions that can be summarized as

$$2\,S_2CN_3^- + I_3^- \longrightarrow 2\,CS_2 + 3\,N_2 + 3\,I^- \text{ (fast)}$$

The rate law derived from this mechanism is the same as the experimental rate law:

$$\text{Rate of consumption of } I_3^- = k[CS_2][N_3^-]$$

Notice that the rate law is first order in the catalyst, carbon disulfide, but zero order in triiodide ion, which appears only in the fast step following the slow step.

A **heterogeneous catalyst** is a catalyst present in a phase different from that of the reactants. The most common heterogeneous catalysts are finely divided or porous solids used in gas-phase or liquid-phase reactions. They are finely divided or porous so that they will provide a large surface area for the elementary reactions that provide the catalytic pathway. One example is the iron catalyst used in the Haber process for ammonia. Another is finely divided nickel, which is used in the hydrogenation of ethene:

$$H_2C{=}CH_2(g) + H_2(g) \longrightarrow H_3C{-}CH_3(g)$$

The reactant is adsorbed on the catalyst's surface. As a reactant molecule attaches to the surface of the catalyst, its bonds are weakened and the reaction can proceed more quickly because the bonds are more easily broken (Fig. 14.36). One important step in the reaction mechanism of the Haber process for the synthesis of ammonia is the adsorption of N_2 molecules on the iron catalyst and the weakening of the strong N≡N triple bond.

Self-Test 14.14A How does a catalyst affect (a) the rate of the reverse reaction; (b) ΔH for the reaction?

[*Answer:* (a) Increases it; (b) has no effect]

Self-Test 14.14B How does a homogeneous catalyst affect (a) the rate law; (b) the equilibrium constant?

Catalysts participate in reactions but are not themselves used up; they provide a reaction pathway with a lower activation energy. Catalysts are classified as either homogeneous or heterogeneous.

14.15 Industrial Catalysts

The catalytic converters of automobiles use catalysts to bring about the complete and rapid combustion of unburned fuel (Fig. 14.37). The mixture of gases leaving an engine includes carbon monoxide, unburned hydrocarbons, and the nitrogen oxides collectively referred to as NO_x. Air pollution is decreased if the carbon compounds are oxidized to carbon dioxide and the NO_x reduced, by another catalyst, to nitrogen. The challenge is to find a catalyst—or a mixture of catalysts—that will accelerate both the

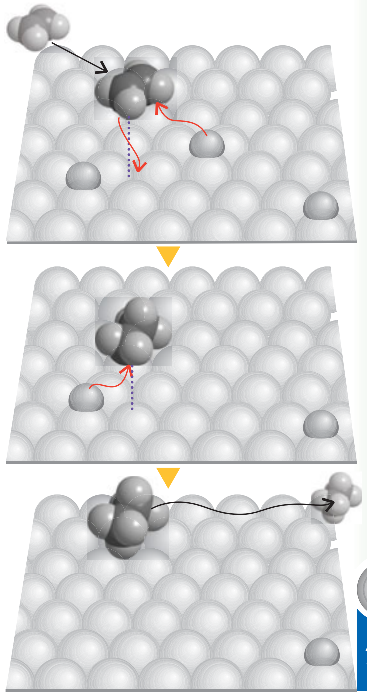

FIGURE 14.36 The reaction between ethene, $CH_2{=}CH_2$, and hydrogen on a catalytic metal surface. In this sequence of images, we see the ethene molecule approaching the metal surface to which hydrogen molecules have already adsorbed: when they adsorb, they dissociate and stick to the surface as hydrogen atoms. Next, after the ethene molecule also sticks to the surface, it meets a hydrogen atom and forms a bond. At this stage, the $\cdot CH_2CH_3$ radical is attached to the surface by one of its carbon atoms until it meets another hydrogen atom; then ethane is formed and escapes from the surface.

Animation 14.36

BOX 14.3 WHAT HAS THIS TO DO WITH . . . THE ENVIRONMENT?

Protecting the Ozone Layer

Every year our planet is bombarded with enough energy from the Sun to destroy all life. Only the ozone in the stratosphere protects us from that onslaught. The ozone, though, is threatened by modern life styles. Chemicals used as coolants and propellants, such as chlorofluorocarbons (CFCs), and the nitrogen oxides in jet exhausts have been found to create holes in Earth's protective ozone layer, particularly over Antarctica. Because they act as catalysts, even small amounts of these chemicals can cause large changes in the vast reaches of the stratosphere.

Ozone forms in the stratosphere in two steps. First, O_2 molecules or other oxygen-containing compounds are broken apart into atoms by sunlight, a process called *photodissociation*:

$$O_2 \xrightarrow{\text{sunlight}, \lambda < 340 \text{ nm}} O + O$$

Then the O atoms, which are reactive radicals with two unpaired electrons, react with the more abundant O_2 molecules to form ozone. The ozone molecules are created in such a high-energy state that their vibrational motions would quickly tear them apart unless another molecule, such as O_2 or N_2, collides with them first. The other molecule, indicated as M, carries off some of the energy:

$$O + O_2 \longrightarrow O_3^*$$
$$O_3^* + M \longrightarrow O_3 + M$$

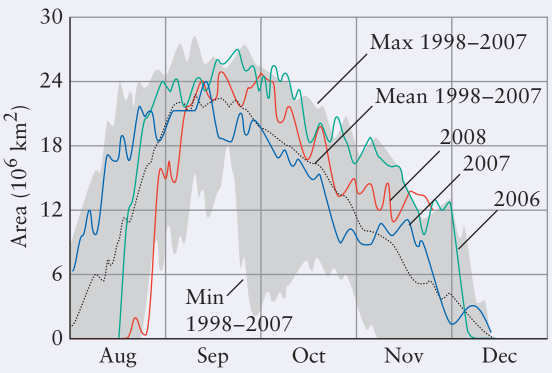
where * denotes a high-energy state. The net reaction, the sum of these two elementary reactions (after multiplying them by 2) and the reaction presented earlier, is $3\,O_2 \longrightarrow 2\,O_3$. Some of the ozone is decomposed by ultraviolet radiation:

$$O_3 \xrightarrow{\text{UV}, \lambda < 340 \text{ nm}} O + O_2$$

The oxygen atom produced in this step can react with oxygen molecules to produce more ozone, and so the ozone concentration in the stratosphere normally remains constant, with seasonal variations. Because the decomposition of ozone absorbs ultraviolet radiation, ozone helps to shield the Earth from radiation damage.

Warnings of the possibility that *androgenic* (human-generated) chemicals can threaten the ozone in the stratosphere began to appear in 1970 and 1971, when Paul Crutzen determined experimentally that NO and NO_2 molecules catalyze the destruction of ozone. Nitrogen monoxide (nitric oxide), NO, is produced naturally in the atmosphere by lightning, but it is also a by-product of combustion in automobile and airplane engines. The NO is then oxidized by the oxygen in air to nitrogen dioxide, NO_2.

Mario Molina and Sherwood Rowland used Crutzen's work and other data in 1974 to build a model of the stratosphere that explained how chlorofluorocarbons could threaten the ozone layer.[1] In 1985, ozone levels over Antarctica were indeed found to be decreasing and had dropped to the lowest ever observed; by the year 2000, the ozone hole extended to Chile. These losses are now known to be global in extent and it has been postulated that they may be contributing to global warming in the Southern Hemisphere.



Variation in the area of the ozone hole over Antarctica from August through December over three years and the overall variation over a decade (shaded).

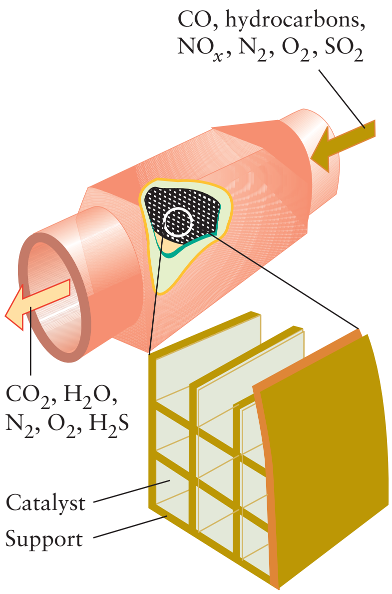


FIGURE 14.37 The catalytic converter of an automobile is made from a mixture of catalysts bonded to a honeycomb ceramic support.

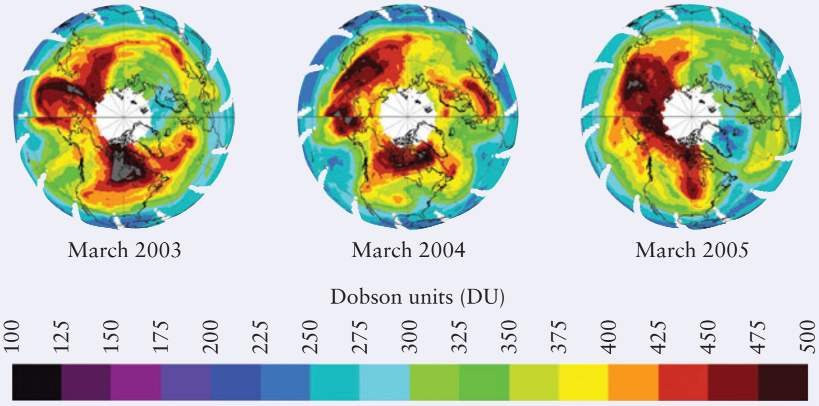
oxidation and the reduction reactions and be active when the car is first started and the engine is cool.

Microporous catalysts are heterogeneous catalysts used in catalytic converters and for many other specialized applications, because of their very large surface areas and reaction specificity. **Zeolites,** for example, are microporous aluminosilicates (see Section 6.7) with three-dimensional structures riddled with hexagonal channels connected by tunnels (Fig. 14.38). The enclosed nature of the active sites in zeolites gives them a special advantage over other heterogeneous catalysts, because an intermediate can be held in place inside the channels until the products form. Moreover, the channels allow products to grow only to a particular size.

One successful application of zeolites is the catalyst ZSM-5, which is used to convert methanol to gasoline. The pores of the zeolite are just large enough to allow



These maps of stratospheric ozone concentration over the North Pole show ozone levels from 2003 to 2005. Normal ozone concentration at temperate latitudes is about 350 DU.

Susan Solomon and James Anderson showed that CFCs produce chlorine atoms and chlorine oxide under the conditions of the ozone layer and identified the CFCs emanating from everyday objects, such as cans of hair spray, refrigerators, and air conditioners, as primary culprits in the destruction of stratospheric ozone. The CFC molecules are not very polar, and so they do not dissolve in rain or the oceans. Instead, they rise to the stratosphere, where they are exposed to ultraviolet radiation from the Sun. They readily dissociate in the presence of this radiation and form chlorine atoms, which destroy ozone by various mechanisms, one of which is

$$Cl\cdot + O_3 \longrightarrow ClO\cdot + O_2$$

$$ClO\cdot + \cdot O\cdot \longrightarrow Cl\cdot + O_2$$

The O atoms are produced when ozone is decomposed by ultraviolet light, as described previously. Notice that the net reaction, $O_3 + O \longrightarrow O_2 + O_2$, does not involve chlorine. Chlorine atoms act as continuously regenerated catalysts, and so even a low abundance can do a lot of damage.

Most nations signed the Montreal Protocol of 1987 and the amendments added in 1992, which required the more dangerous CFCs to be phased out by 1996. The concentration of ozone in the stratosphere is measured by NASA's Total Ozone Mapping Spectrometer (TOMS). The TOMS data show that the levels of compounds that deplete ozone are decreasing and that the ozone hole has been shrinking, although in 2008 that trend reversed and it began to grow again. It is thought that if the Montreal Protocol continues to be observed and there are no major volcanic eruptions (which release dust that accelerates the destruction of ozone), the ozone levels in the stratosphere may return to protective levels.

product hydrocarbons consisting of about eight carbon atoms to escape, so the chains do not grow too long and equilibrium is never reached.

Zeolite catalysts that adsorb harmful pollutants preferentially have been developed for use in industry and in catalytic converters for vehicles. In catalytic converters, they trap nitrogen oxides so that they can be reduced to harmless nitrogen gas. Catalysts with a different formulation trap incompletely burned hydrocarbons and oxidize them to carbon dioxide.

Catalysts can be **poisoned,** or inactivated. A common cause of such poisoning is the adsorption of a molecule so tightly to the catalyst that it seals the surface of the catalyst against further reaction. Some heavy metals, especially lead, are very potent poisons for heterogeneous catalysts, which is why lead-free gasoline must be used in engines fitted with catalytic converters. The elimination of lead has the further benefit of decreasing the amount of poisonous lead in the environment.

Microporous catalysts are heterogenous catalysts such as zeolites that have large surface areas.

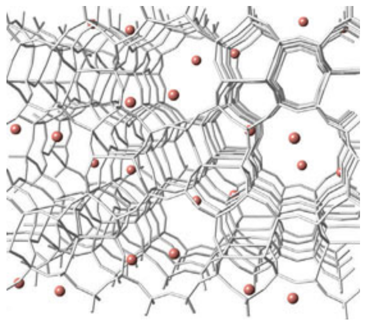

FIGURE 14.38 The structure of the ZSM-5 zeolite catalyst. Reactants diffuse through the channels, which are narrow enough to hold intermediates in positions favorable for reaction.

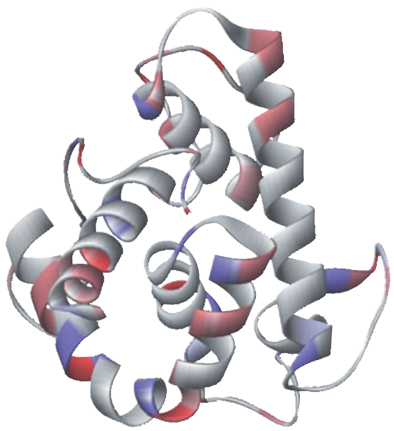

FIGURE 14.39 The lysozyme molecule is a typical enzyme molecule. Lysozyme is present in a number of places in the body, including tears and the mucus in the nose. One of its functions is to attack the cell walls of bacteria and destroy them. This "ribbon" representation shows only the general arrangement of the atoms to emphasize the overall shape of the molecule; the ribbon actually consists of amino acids linked together (Section 19.13).

14.16 Living Catalysts: Enzymes

Living cells contain thousands of different kinds of catalysts, each of which is necessary to life. Many of these catalysts are proteins called *enzymes*, large molecules with a slotlike active site, where reaction takes place (Fig. 14.39). The **substrate,** the molecule on which the enzyme acts, fits into the slot as a key fits into a lock (Fig. 14.40). However, unlike an ordinary lock, a protein molecule distorts slightly as the substrate molecule approaches, and its ability to undergo the correct distortion also determines whether the "key" will fit. This refinement of the original lock-and-key model is known as the **induced-fit mechanism** of enzyme action.

Once in the active site, the substrate undergoes reaction. The product is then released for use in the next stage, which is controlled by another enzyme, and the original enzyme molecule is free to receive the next substrate molecule. One example of an enzyme is the amylase present in your mouth. The amylase in saliva helps to break down starches in food into the more easily digested glucose. If you chew a cracker long enough, you can notice the increased sweetness.

The kinetics of enzyme reactions were first studied by the German chemists Leonor Michaelis and Maud Menten in the early part of the twentieth century. They found that, when the concentration of substrate is low, the rate of an enzyme-catalyzed reaction increases with the concentration of the substrate, as shown in the plot in Fig. 14.41. However, when the concentration of substrate is high, the reaction rate depends only on the concentration of the enzyme. In the **Michaelis–Menten mechanism** of enzyme reaction, the substrate, S, and the bound enzyme–substrate complex, ES, form and separate:

$$\mathrm{E + S \rightleftharpoons ES} \qquad \text{forward: second order,} \qquad \text{Rate} = k_1[\mathrm{E}][\mathrm{S}]$$
$$\text{reverse: first order,} \qquad \text{Rate} = k_1'[\mathrm{ES}]$$

The complex decays with first-order kinetics, releasing the enzyme to act again:

$$\mathrm{ES \longrightarrow E + product} \qquad \text{forward: first order,} \qquad \text{Rate} = k_2[\mathrm{ES}]$$

When the overall rate law is worked out (see Exercise 14.94), we find that

$$\text{Rate of formation of product} = \frac{k_2[\mathrm{E}]_0[\mathrm{S}]}{K_\mathrm{M} + [\mathrm{S}]} \qquad \textbf{(19a)*}$$

where $[\mathrm{E}]_0$ is the total concentration of enzyme (bound plus unbound) and the **Michaelis constant,** K_M, is

$$K_\mathrm{M} = \frac{k_1' + k_2}{k_1} \qquad \textbf{(19b)*}$$

When we plot the rate given by Eq. 19a against the concentration of substrate, we get a curve exactly like the one observed.

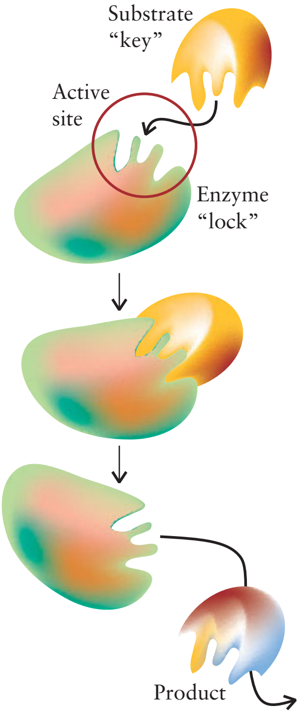

FIGURE 14.40 In the lock-and-key model of enzyme action, the correct substrate is recognized by its ability to fit into the active site like a key into a lock. In a refinement of this model, the enzyme changes its shape slightly as the key enters.

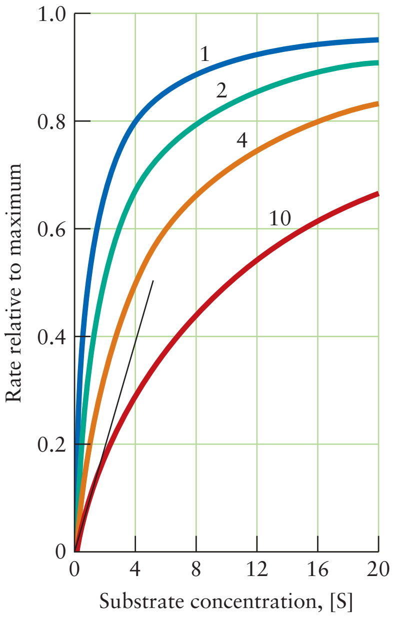

FIGURE 14.41 A plot of the rate of an enzyme-catalyzed reaction (relative to its maximum value, $k_2[E]_0$, when S is in very high concentration) as a function of concentration of substrate for various values of K_M. At low substrate concentrations, the rate of reaction is directly proportional to the substrate concentration (as indicated by the black line for $K_M = 10$). At high substrate concentrations, the rate becomes constant at $k_2[E]_0$ once the enzyme molecules are "saturated" with substrate. The units of [S] are the same as those of K_M.

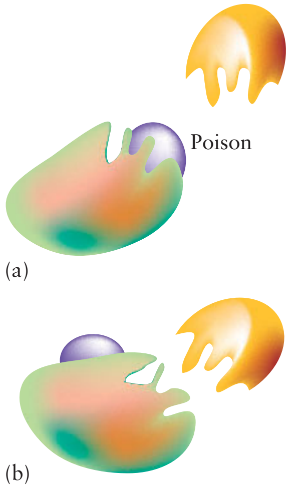

FIGURE 14.42 (a) An enzyme poison (represented by the blue sphere) can act by attaching so strongly to the active site that it blocks the site, thereby taking the enzyme out of action. (b) Alternatively, the poison molecule may attach elsewhere, so distorting the enzyme molecule and its active site that the substrate no longer fits.

One form of biological poisoning mirrors the effect of lead on a catalytic converter. The activity of an enzyme is destroyed if an alien substrate attaches too strongly to the enzyme's active site, because then the site is blocked and made unavailable to the true substrate (Fig. 14.42). As a result, the chain of biochemical reactions in the cell stops, and the cell dies. The action of nerve gases is believed to stem from their ability to block the enzyme-controlled reactions that allow impulses to travel through nerves. Arsenic, that favorite of fictional poisoners, acts in a similar way. After ingestion as As(V) in the form of arsenate ions (AsO_4^{3-}), it is reduced to As(III), which binds to enzymes and inhibits their action.

Enzymes are biological catalysts that function by modifying substrate molecules to promote reaction.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Determine the order of a reaction, its rate law, and its rate constant from experimental data (Examples 14.1 and 14.2 and Self-Tests 14.2 and 14.3).

❑ 2 Calculate a concentration, time, or rate constant by using an integrated rate law (Examples 14.3, 14.4, and 14.5).

❑ 3 For a first-order process, calculate the rate constant, elapsed time, and amount remaining from the half-life (Example 14.6 and Self-Test 14.9).

❑ 4 Deduce a rate law from a mechanism (Example 14.7).

❑ 5 Show how the equilibrium constant is related to the forward and reverse rate constants of the elementary reactions contributing to an overall reaction (Section 14.10).

❑ 6 Use the Arrhenius equation and temperature dependence of a rate constant to determine an activation energy (Example 14.8).

❑ 7 Use the activation energy to find the rate constant at a given temperature (Example 14.9).

❑ 8 Show how collision theory and transition state theory account for the temperature dependence of reactions (Sections 14.12 and 14.13).

❑ 9 Describe the action of catalysts in terms of a reaction profile (Section 14.14).

❑ 10 Write a rate law for the action of enzymes (Section 14.16).

EXERCISES

Exercises marked C require calculus.

All rates are unique reaction rates unless otherwise stated.

Reaction Rates

14.1 Complete the following statements relating to the production of ammonia by the Haber process, for which the overall reaction is $N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g)$. (a) The rate of consumption of N_2 is ________________ times the rate of consumption of H_2. (b) The rate of formation of NH_3 is ________________ times the rate of consumption of H_2. (c) The rate of formation of NH_3 is ________________ times the rate of consumption of N_2.

14.2 Complete the following statements for the reaction $6\,Li(s) + N_2(g) \longrightarrow 2\,Li_3N(s)$. The rate of consumption of N_2 is ________________ times the rate of formation of Li_3N. (b) The rate of formation of Li_3N is ________________ times the rate of consumption of Li. (c) The rate of consumption of N_2 is ________________ times the rate of consumption of Li.

14.3 (a) The rate of formation of dichromate ions is 0.14 $mol{\cdot}L^{-1}{\cdot}s^{-1}$ in the reaction $2\,CrO_4^{2-}(aq) + 2\,H^+(aq) \longrightarrow Cr_2O_7^{2-}(aq) + H_2O(l)$. What is the rate of reaction of chromate ions in the reaction? (b) What is the unique rate of the reaction?

14.4 (a) In the reaction $3\,ClO^-(aq) \longrightarrow 2\,Cl^-(aq) + ClO_3^-(aq)$, the rate of formation of Cl^- is 3.6 $mol{\cdot}L^{-1}{\cdot}min^{-1}$. What is the rate of reaction of ClO^-? (b) What is the unique rate of the reaction?

14.5 (a) Nitrogen dioxide, NO_2, decomposes at 6.5 $mmol{\cdot}L^{-1}{\cdot}s^{-1}$ by the reaction $2\,NO_2(g) \longrightarrow 2\,NO(g) + O_2(g)$. Determine the rate of formation of O_2. (b) What is the unique rate of the reaction?

14.6 Manganate ions, MnO_4^{2-}, react at 2.0 $mol{\cdot}L^{-1}{\cdot}min^{-1}$ in acidic solution to form permanganate ions and manganese(IV) oxide: $3\,MnO_4^{2-}(aq) + 4\,H^+(aq) \longrightarrow 2\,MnO_4^-(aq) + MnO_2(s) + 2\,H_2O(l)$. (a) What is the rate of formation of permanganate ions? (b) What is the rate of reaction of $H^+(aq)$? (c) What is the unique rate of the reaction?

14.7 The decomposition of gaseous hydrogen iodide, $2\,HI(g) \longrightarrow H_2(g) + I_2(g)$, gives the data shown here for 700. K.

Time (s)	0.	1000.	2000.	3000.	4000.	5000.
[HI] ($mmol{\cdot}L^{-1}$)	10.0	4.4	2.8	2.1	1.6	1.3

(a) Use a graphing calculator or standard graphing software, such as that on the Web site for this book, to plot the concentration of HI as a function of time. (b) Estimate the rate of decomposition of HI at each time. (c) Plot the concentrations of H_2 and I_2 as a function of time on the same graph.

14.8 The decomposition of gaseous dinitrogen pentoxide in the reaction $2\,N_2O_5(g) \longrightarrow 4\,NO_2(g) + O_2(g)$ gives the data shown here at 298 K. (a) Using a graphing calculator or standard graphing software, such as that on the Web site for this book, plot the concentration of N_2O_5 as a function of time. (b) Estimate the rate of decomposition of N_2O_5 at each time. (c) Plot the concentrations of NO_2 and O_2 as a function of time on the same graph.

Time (s)	0.	1.11	2.22	3.33	4.44
[N_2O_5] ($mmol{\cdot}L^{-1}$)	2.15	1.88	1.64	1.43	1.25

Rate Laws and Reaction Order

Rate constants are listed in Table 14.1.

14.9 Express the units for rate constants when the concentrations are in moles per liter and time is in seconds for (a) zero-order reactions; (b) first-order reactions; (c) second-order reactions.

14.10 Because partial pressures are proportional to concentrations, rate laws for gas-phase reactions can also be expressed in terms of partial pressures, for instance, as Rate $= kP_X$ for a first-order reaction of a gas X. What are the units for the rate constants when partial pressures are expressed in torr and time is expressed in seconds for (a) zero-order reactions; (b) first-order reactions; (c) second-order reactions?

14.11 Dinitrogen pentoxide, N_2O_5, decomposes by a first-order reaction. What is the initial rate of decomposition of N_2O_5 when 3.45 g of N_2O_5 is confined in a 0.750-L container and heated to 65°C? For this reaction, $k = 5.2 \times 10^{-3}\ s^{-1}$ in the rate law (for the rate of decomposition of N_2O_5).

14.12 Ethane, C_2H_6, dissociates into methyl radicals by a first-order reaction at elevated temperatures. If 120. mg of ethane is confined to a 500.-mL reaction vessel and heated to 700°C, what is the initial rate of ethane decomposition if $k = 5.5 \times 10^{-4}\ s^{-1}$ in the rate law (for the rate of dissociation of C_2H_6)?

14.13 When 0.52 g of H_2 and 0.19 g of I_2 are confined to a 750.-mL reaction vessel and heated to 700. K, they react by a second-order process (first order in each reactant), with $k = 0.063\ L{\cdot}mol^{-1}{\cdot}s^{-1}$ in the rate law (for the rate of formation of HI). (a) What is the initial reaction rate? (b) By what factor does the reaction rate increase if the concentration of H_2 present in the mixture is doubled?

14.14 When 420. mg of NO_2 is confined to a 150.-mL reaction vessel and heated to 300°C, it decomposes by a second-order process. In the rate law for the decomposition of NO_2, $k = 0.54\ L{\cdot}mol^{-1}{\cdot}s^{-1}$. (a) What is the initial reaction rate? (b) How does the reaction rate change (and by what factor) if the mass of NO_2 present in the container is increased to 750. mg?

14.15 In the reaction $CH_3Br(aq) + OH^-(aq) \longrightarrow CH_3OH(aq) + Br^-(aq)$, when the OH^- concentration alone was doubled, the rate doubled; when the CH_3Br concentration alone was increased by a factor of 1.2, the rate increased by a factor of 1.2. Write the rate law for the reaction.

14.16 In the reaction $4\,Fe^{2+}(aq) + O_2(g) + 4\,H_3O^+(aq) \longrightarrow 4\,Fe^{3+}(aq) + 6\,H_2O(l)$, when the Fe^{2+} concentration alone was doubled, the rate increased by a factor of 8; when both the Fe^{2+} and the O_2 concentrations were increased by a factor of 2, the rate increased by a factor of 16. When the concentrations of all three reactants were doubled, the rate increased by a factor of 32. What is the rate law for the reaction?

14.17 The following rate data were collected for the reaction $2\,A(g) + 2\,B(g) + C(g) \longrightarrow 3\,G(g) + 4\,F(g)$:

	Initial concentration ($mmol{\cdot}L^{-1}$)			Initial rate
Experiment	$[A]_0$	$[B]_0$	$[C]_0$	$((mmol\ G){\cdot}L^{-1}{\cdot}s^{-1})$
1	10.	100.	700.	2.0
2	20.	100.	300.	4.0
3	20.	200.	200.	16
4	10.	100.	400.	2.0
5	4.62	0.177	12.4	?

(a) What is the order for each reactant and the overall order of the reaction? (b) Write the rate law for the reaction. (c) Determine the reaction rate constant. (d) Predict the initial rate for Experiment 5.

14.18 The following kinetic data were obtained for the reaction $A(g) + 2\,B(g) \longrightarrow$ product.

	Initial concentration ($mol{\cdot}L^{-1}$)		Initial rate
Experiment	$[A]_0$	$[B]_0$	$(mol{\cdot}L^{-1}{\cdot}s^{-1})$
1	0.60	0.30	12.6
2	0.20	0.30	1.4
3	0.60	0.10	4.2
4	0.17	0.25	?

(a) What is the order with respect to each reactant, and the overall order of the reaction? (b) Write the rate law for the reaction. (c) From the data, determine the value of the rate constant. (d) Use the data to predict the reaction rate for Experiment 4.

14.19 The following data were obtained for the reaction $A + B + C \longrightarrow$ products:

	Initial concentration ($mmol{\cdot}L^{-1}$)			Initial rate
Experiment	$[A]_0$	$[B]_0$	$[C]_0$	$((mmol\ A){\cdot}L^{-1}{\cdot}s^{-1})$
1	1.25	1.25	1.25	8.7
2	2.5	1.25	1.25	17.4
3	1.25	3.02	1.25	50.8
4	1.25	3.02	3.75	457
5	3.01	1.00	1.15	?

(a) Write the rate law for the reaction. (b) What is the order of the reaction? (c) Determine the value of the rate constant. (d) Use the data to predict the reaction rate for Experiment 5.

14.20 The following kinetic data were obtained for the reaction $3\,A(g) + C(g) \longrightarrow$ product:

	Initial concentration ($mol{\cdot}L^{-1}$)		Initial rate
Experiment	$[A]_0$	$[C]_0$	$(mol{\cdot}L^{-1}{\cdot}s^{-1})$
1	1.72	2.44	0.68
2	3.44	2.44	5.44
3	1.72	0.10	2.8×10^{-2}
4	2.91	1.33	?

(a) What is the order with respect to each reactant, and the overall order of the reaction? (b) Write the rate law for the reaction. (c) From the data, determine the value of the rate constant. (d) Use the data to predict the reaction rate for Experiment 4.

Integrated Rate Laws

14.21 Beta blockers are drugs that are used to manage hypertension. It is important for doctors to know how rapidly a beta blocker is eliminated from the body. A certain beta blocker is eliminated in a first-order process with a rate constant of $7.6 \times 10^{-3}\ min^{-1}$. at normal body temperature (37°). A patient is given 20. mg of the drug. What mass of the drug remains in the body 5.0 h after administration?

14.22 In the brewing of beer, ethanal, which smells like green apples, is an intermediate in the formation of ethanol. Ethanal decomposes in the following first-order reaction: $CH_3CHO(g) \longrightarrow CH_4(g) + CO(g)$. At an elevated temperature the rate constant for the decomposition is $1.5 \times 10^{-3}\ s^{-1}$. What concentration of ethanal, which had an initial concentration of $0.120\ mol{\cdot}L^{-1}$, remains 20.0 min after the start of its decomposition at this temperature?

14.23 Determine the rate constant for each of the following first-order reactions, in each case expressed for the rate of loss of A: (a) $A \longrightarrow B$, given that the concentration of A decreases to one-half its initial value in 1000. s; (b) $A \longrightarrow B$, given that the concentration of A decreases from $0.67\ mol{\cdot}L^{-1}$ to $0.53\ mol{\cdot}L^{-1}$ in 25 s; (c) $2\,A \longrightarrow B + C$, given that $[A]_0 = 0.153\ mol{\cdot}L^{-1}$ and that after 115 s the concentration of B rises to $0.034\ mol{\cdot}L^{-1}$.

14.24 Determine the rate constant for each of the following first-order reactions: (a) $2\,A \longrightarrow B + C$, given that the concentration of A decreases to one-fourth its initial value in 61 min; (b) $2\,A \longrightarrow B + C$, given that $[A]_0 = 0.021\ mol{\cdot}L^{-1}$ and that after 45 s the concentration of B increases to $0.00125\ mol{\cdot}L^{-1}$; (c) $2\,A \longrightarrow 3\,B + C$, given that $[A]_0 = 0.060\ mol{\cdot}L^{-1}$ and that after 10.8 min the concentration of B rises to $0.040\ mol{\cdot}L^{-1}$. In each case, write the rate law for the rate of loss of A.

14.25 Dinitrogen pentoxide, N_2O_5, decomposes by first-order kinetics with a rate constant of $3.7 \times 10^{-5}\ s^{-1}$ at 298 K. (a) What is the half-life (in hours) for the decomposition of N_2O_5 at 298 K? (b) If $[N_2O_5]_0 = 0.0567\ mol{\cdot}L^{-1}$, what will be the concentration of N_2O_5 after 3.5 h? (c) How much time (in minutes) will elapse before the N_2O_5 concentration decreases from $0.0567\ mol{\cdot}L^{-1}$ to $0.0135\ mol{\cdot}L^{-1}$?

14.26 Dinitrogen pentoxide, N_2O_5, decomposes by first-order kinetics with a rate constant of $0.15\ s^{-1}$ at 353 K. (a) What is the half-life (in seconds) for the decomposition of N_2O_5 at 353 K? (b) If $[N_2O_5]_0 = 0.0567\ mol{\cdot}L^{-1}$, what will be the concentration of N_2O_5 after 2.0 s? (c) How much time (in minutes) will elapse before the N_2O_5 concentration decreases from $0.0567\ mol{\cdot}L^{-1}$ to $0.0135\ mol{\cdot}L^{-1}$?

14.27 The half-life for the first-order decomposition of A is 355 s. How much time must elapse for the concentration of A to decrease to (a) $\frac{1}{8}\,[A]_0$; (b) one-fourth of its initial concentration; (c) 15% of its initial concentration; (d) one-ninth of its initial concentration?

14.28 The first-order rate constant for the photodissociation of A is $6.85 \times 10^{-2}\ min^{-1}$. Calculate the time needed for the concentration of A to decrease to (a) $\frac{1}{8}\,[A]_0$; (b) 10.% of its initial concentration; (c) one-third of its initial concentration.

14.29 For the first-order reaction $A \longrightarrow 3\,B + C$, when $[A]_0 = 0.015\ mol{\cdot}L^{-1}$, the concentration of B increases to $0.018\ mol{\cdot}L^{-1}$ in 3.0 min. (a) What is the rate constant for the reaction expressed as the rate of loss of A? (b) How much more time would be needed for the concentration of B to increase to $0.030\ mol{\cdot}L^{-1}$?

14.30 Pyruvic acid is an intermediate in the fermentation of grains. During fermentation the enzyme pyruvate carboxylase causes the pyruvate ion to release carbon dioxide. In one experiment a 200.-mL aqueous solution of the pyruvate in a sealed, rigid 500.-mL flask at 293 K had an initial concentration of 3.23 $mmol{\cdot}L^{-1}$. Because the concentration of the enzyme was kept constant, the reaction was pseudo-first order in pyruvate ion. The elimination of CO_2 by the reaction was monitored by measuring the partial pressure of the CO_2 gas. The pressure of the gas was found to rise from zero to 100. Pa in 522 s. What is the rate constant of the pseudo-first order reaction?

14.31 The data below were collected for the reaction $2\ HI(g) \longrightarrow H_2(g) + I_2(g)$ at 580 K.

Time (s)	0	1000.	2000.	3000.	4000.
[HI] ($mol{\cdot}L^{-1}$)	1.0	0.11	0.061	0.041	0.031

(a) Using a graphing calculator or graphing software, such as that on the Web site for this book, plot the data in an appropriate fashion to determine the order of the reaction. (b) From the graph, determine the rate constant for (i) the rate law for the loss of HI and (ii) the unique rate law.

14.32 The data below were collected for the reaction $H_2(g) + I_2(g) \longrightarrow 2\ HI(g)$ at 780 K. (a) Using a graphing calculator or graphing software, such as that on the Web site for this book, plot the data in an appropriate fashion to determine the order of the reaction. (b) From the graph, determine the rate constant for the rate of consumption of I_2.

Time (s)	0	1.0	2.0	3.0	4.0
[I_2] ($mmol{\cdot}L^{-1}$)	1.00	0.43	0.27	0.20	0.16

14.33 The half-life for the second-order reaction of a substance A is 50.5 s when $[A]_0 = 0.84\ mol{\cdot}L^{-1}$. Calculate the time needed for the concentration of A to decrease to (a) one-sixteenth; (b) one-fourth; (c) one-fifth of its original value.

14.34 Determine the rate constant for each of the following second-order reactions: (a) $2\ A \longrightarrow B + 2\ C$, given that the concentration of A decreases from 2.50 $mmol{\cdot}L^{-1}$ to 1.25 $mmol{\cdot}L^{-1}$ in 100 s; (b) $A \longrightarrow C + 2\ D$, given that $[A]_0 = 0.300\ mol{\cdot}L^{-1}$ and that the concentration of C increases to 0.010 $mol{\cdot}L^{-1}$ in 200. s. In each case, express your results in terms of the rate law for the loss of A.

14.35 Sulfuryl chloride, SO_2Cl_2, decomposes by first-order kinetics, and $k = 2.81 \times 10^{-3}\ min^{-1}$ at a certain temperature. (a) Determine the half-life for the reaction. (b) Determine the time needed for the concentration of SO_2Cl_2 to decrease to 10% of its initial concentration. (c) If 14.0 g of SO_2Cl_2 is sealed in a 2500.-L reaction vessel and heated to the specified temperature, what mass will remain after 1.5 h?

14.36 Ethane, C_2H_6, forms $\cdot CH_3$ radicals at 700.°C in a first-order reaction, for which $k = 1.98\ h^{-1}$. (a) What is the half-life for the reaction? (b) Calculate the time needed for the amount of ethane to fall from 1.15×10^{-3} mol to 2.35×10^{-4} mol in a 500.-mL reaction vessel at 700.°C. (c) How much of a 6.88-mg sample of ethane in a 500.-mL reaction vessel at 700.°C will remain after 45 min?

14.37 Determine the time required for each of the following second-order reactions to take place: (a) $2\ A \longrightarrow B + C$, for the concentration of A to decrease from 0.10 $mol{\cdot}L^{-1}$ to 0.080 $mol{\cdot}L^{-1}$, given that $k = 0.015\ L{\cdot}mol^{-1}{\cdot}min^{-1}$ for the rate law expressed in terms of the loss of A; (b) $A \longrightarrow 2\ B + C$, when $[A]_0 = 0.15\ mol{\cdot}L^{-1}$, for the concentration of B to increase to 0.19 $mol{\cdot}L^{-1}$, given that $k = 0.0035\ L{\cdot}mol^{-1}{\cdot}min^{-1}$ in the rate law for the loss of A.

14.38 The second-order rate constant for the decomposition of NO_2 (to NO and O_2) at 573 K is 0.54 $L{\cdot}mol^{-1}{\cdot}s^{-1}$. Calculate the time for an initial NO_2 concentration of 0.20 $mol{\cdot}L^{-1}$ to decrease to (a) one-half; (b) one-sixteenth; (c) one-ninth of its initial concentration.

C **14.39** Suppose a reaction has the form $a\ A \longrightarrow$ products and we consider the unique rate of the reaction and write the rate law Rate = k[A]. Derive an expression for the concentration of A at a time t and for the half-life of A in terms of a and k.

C **14.40** Suppose a reaction has the form $a\ A \longrightarrow$ products and we consider the unique rate of the reaction and write the rate law Rate = $k[A]^2$. Derive an expression for the concentration of A at a time t in terms of a and k.

C **14.41** Derive an expression for the half-life of the reactant A that decays by a third-order reaction with rate constant k.

C **14.42** Derive an expression for the half-life of the reactant A that decays by an nth-order reaction (with $n > 1$) with rate constant k.

Reaction Mechanisms

14.43 Write the overall reaction for the mechanism proposed below and identify any reaction intermediates.

Step 1 $AC + B \longrightarrow AB + C$

Step 2 $AC + AB \longrightarrow A_2B + C$

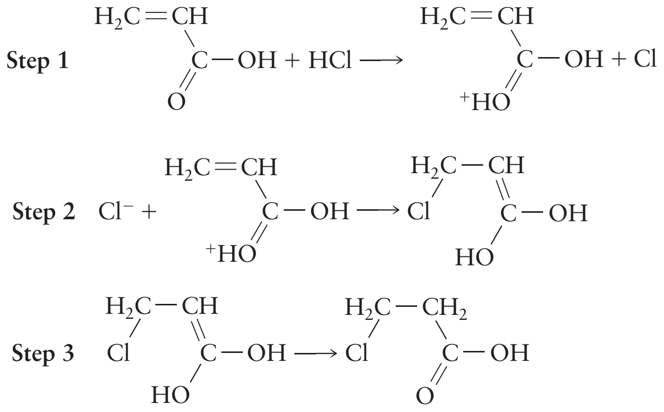
14.44 Write the overall reaction for the mechanism proposed below and identify any reaction intermediates.

Step 1 $C_4H_9Br \longrightarrow C_4H_9^+ + Br^-$

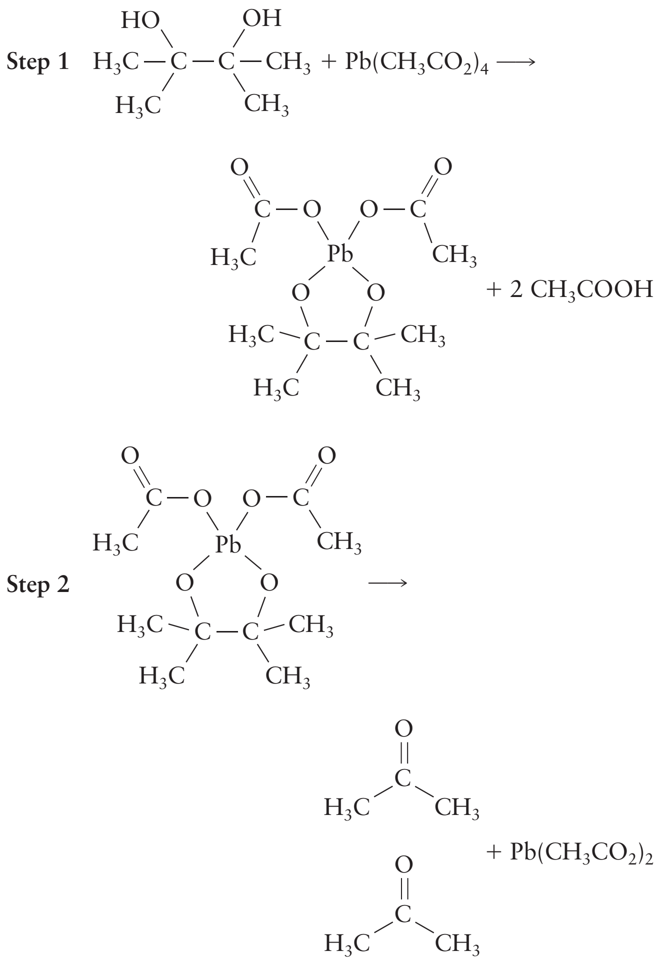
Step 2 $C_4H_9^+ + H_2O \longrightarrow C_4H_9OH_2^+$

Step 3 $C_4H_9OH_2^+ + H_2O \longrightarrow C_4H_9OH + H_3O^+$

14.45 Write the overall reaction for the following proposed mechanism and identify any reaction intermediates:



14.46 Lead(IV) acetate cleaves organic diols such as 2,3-dihydroxy-2,3-dimethylbutane in aqueous solution to give ketones. Write the overall reaction for the following proposed mechanism and identify any reaction intermediates:



14.47 The contribution to the destruction of the ozone layer caused by high-flying aircraft has been attributed to the following mechanism:

Step 1 $O_3 + NO \longrightarrow NO_2 + O_2$

Step 2 $NO_2 + O \longrightarrow NO + O_2$

(a) Write the overall reaction. (b) Write the rate law for each step and indicate its molecularity. (c) What is the reaction intermediate? (d) A catalyst is a substance that accelerates the rate of a reaction and is regenerated in the process. What is the catalyst in the reaction? (See Box 14.3.)

14.48 A reaction was believed to occur by the following mechanism.

Step 1 $A_2 \longrightarrow A + A$

Step 2 $A + A + B \longrightarrow A_2B$

Step 3 $A_2B + C \longrightarrow A_2 + BC$

(a) Write the overall reaction. (b) Write the rate law for each step and indicate its molecularity. (c) What are the reaction intermediates? (d) A catalyst is a substance that accelerates the rate of a reaction and is regenerated in the process. What is the catalyst in the reaction?

14.49 The following mechanism has been proposed for the reaction between nitric oxide and bromine:

Step 1 $NO + Br_2 \longrightarrow NOBr_2$ (slow)

Step 2 $NOBr_2 + NO \longrightarrow NOBr + NOBr$ (fast)

Write the rate law for the formation of NOBr implied by this mechanism.

14.50 The mechanism proposed for the oxidation of iodide ion by the hypochlorite ion in aqueous solution is as follows:

Step 1 $ClO^- + H_2O \longrightarrow HClO + OH^-$ and its reverse (both fast, equilibrium)

Step 2 $I^- + HClO \longrightarrow HIO + Cl^-$ (slow)

Step 3 $HIO + OH^- \longrightarrow IO^- + H_2O$ (fast)

Write the rate law for the formation of HIO implied by this mechanism.

14.51 Three mechanisms for the reaction $NO_2(g) + CO(g) \longrightarrow CO_2(g) + NO(g)$ have been proposed:

(a) **Step 1** $NO_2 + CO \longrightarrow CO_2 + NO$

(b) **Step 1** $NO_2 + NO_2 \longrightarrow NO + NO_3$ (slow)
Step 2 $NO_3 + CO \longrightarrow NO_2 + CO_2$ (fast)

(c) **Step 1** $NO_2 + NO_2 \longrightarrow NO + NO_3$ and its reverse (both fast, equilibrium)
Step 2 $NO_3 + CO \longrightarrow NO_2 + CO_2$ (slow)

Which mechanism agrees with the following rate law: Rate $= k[NO_2]^2$? Explain your reasoning.

14.52 When the rate of the reaction $2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g)$ was studied, the rate was found to double when the O_2 concentration alone was doubled but to quadruple when the NO concentration alone was doubled. Which of the following mechanisms accounts for these observations? Explain your reasoning.

(a) **Step 1** $NO + O_2 \longrightarrow NO_3$ and its reverse (both fast, equilibrium)
Step 2 $NO + NO_3 \longrightarrow NO_2 + NO_2$ (slow)

(b) **Step 1** $NO + NO \longrightarrow N_2O_2$ (slow)
Step 2 $O_2 + N_2O_2 \longrightarrow N_2O_4$ (fast)
Step 3 $N_2O_4 \longrightarrow NO_2 + NO_2$ (fast)

Rates and Equilibrium

14.53 Determine whether each of the following statements is true or false. If a statement is false, explain why. (a) For a reaction with a very large equilibrium constant, the rate constant of the forward reaction is much larger than the rate constant of the reverse reaction. (b) At equilibrium, the rate constants of the forward and reverse reactions are equal. (c) Increasing the concentration of a reactant increases the rate of a reaction by increasing the rate constant in the forward direction.

14.54 Determine whether each of the following statements is true or false. If a statement is false, explain why. (a) The equilibrium constant for a reaction equals the rate constant for the forward reaction divided by the rate constant for the reverse reaction. (b) In a reaction that is a series of equilibrium steps, the overall equilibrium constant is equal to the product of all the forward rate constants divided by the product of all the reverse rate constants. (c) Increasing the concentration of a product increases the rate of the reverse reaction, and so the rate of the forward reaction must then increase, too.

C **14.55** Consider the reaction $A \rightleftarrows B$, which is first order in each direction with rate constants k and k'. Initially, only A is present. Show that the concentrations approach their equilibrium values at a rate that depends on k and k'.

C **14.56** Repeat Exercise 14.55 for the same reaction taken to be second-order in each direction.

The Effect of Temperature

14.57 (a) Using a graphing calculator or standard graphing software, such as that on the Web site for this book, make an appropriate Arrhenius plot of the data shown here for the conversion of cyclopropane into propene and calculate the activation energy for the reaction. (b) What is the value of the rate constant at 600°C?

T (K)	750.	800.	850.	900.
k (s^{-1})	1.8×10^{-4}	2.7×10^{-3}	3.0×10^{-2}	0.26

14.58 (a) Using a graphing calculator or standard graphing software, such as that on the Web site for this book, make an appropriate Arrhenius plot of the data shown here for the decomposition of iodoethane into ethene and hydrogen iodide, $C_2H_5I(g) \longrightarrow C_2H_4(g) + HI(g)$, and determine the activation energy for the reaction. (b) What is the value of the rate constant at 400°C?

T (K)	660	680	720	760
k (s^{-1})	7.2×10^{-4}	2.2×10^{-3}	1.7×10^{-2}	0.11

14.59 The rate constant of the first-order reaction $2\ N_2O(g) \longrightarrow 2\ N_2(g) + O_2(g)$ is $0.76\ s^{-1}$ at 1000. K and $0.87\ s^{-1}$ at 1030. K. Calculate the activation energy of the reaction.

14.60 The rate constant of the second-order reaction $2\ HI(g) \longrightarrow H_2(g) + I_2(g)$ is $2.4 \times 10^{-6}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$ at 575 K and $6.0 \times 10^{-5}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$ at 630. K. Calculate the activation energy of the reaction.

14.61 The rate constant of the reaction $O(g) + N_2(g) \longrightarrow NO(g) + N(g)$, which takes place in the stratosphere, is $9.7 \times 10^{10}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$ at 800.°C. The activation energy of the reaction is $315\ kJ{\cdot}mol^{-1}$. Determine the rate constant at 700.°C. (See Box 14.3.)

14.62 The rate constant of the reaction between CO_2 and OH^- in aqueous solution to give the HCO_3^- ion is $1.5 \times 10^{10}\ L{\cdot}mol^{-1}{\cdot}s^{-1}$ at 25°C. Determine the rate constant at blood temperature (37°C), given that the activation energy for the reaction is $38\ kJ{\cdot}mol^{-1}$.

14.63 The rate constant for the decomposition of N_2O_5 at 45°C is $k = 5.1 \times 10^{-4}\ s^{-1}$. The activation energy for the reaction is $103\ kJ{\cdot}mol^{-1}$. Determine the value of the rate constant at 50°C.

14.64 Ethane, C_2H_6, dissociates into methyl radicals at 700.°C with a rate constant $k = 5.5 \times 10^{-4}\ s^{-1}$. Determine the rate constant at 800.°C, given that the activation energy of the reaction is $384\ kJ{\cdot}mol^{-1}$.

14.65 For the reversible, one-step reaction , $2\ A \rightleftarrows B + C$, the forward rate constant for the formation of B is $265\ L{\cdot}mol^{-1}{\cdot}min^{-1}$ and the rate constant for the reverse reaction is $392\ L{\cdot}mol^{-1}{\cdot}min^{-1}$. The activation energy for the forward reaction is $39.7\ kJ{\cdot}mol^{-1}$ and that of the reverse reaction is $25.4\ kJ{\cdot}mol^{-1}$. (a) What is the equilibrium constant for the reaction? (b) Is the reaction exothermic or endothermic? (c) What will be the effect of raising the temperature on the rate constants and the equilibrium constant?

14.66 For the reversible, one-step reaction $A + B \rightleftarrows C + D$, the forward rate constant is $52.4\ L{\cdot}mol^{-1}{\cdot}h^{-1}$ and the rate constant for the reverse reaction is $32.1\ L{\cdot}mol^{-1}{\cdot}h^{-1}$. The activation energy was found to be $35.2\ kJ{\cdot}mol^{-1}$ for the forward reaction and $44.0\ kJ{\cdot}mol^{-1}$ for the reverse reaction. (a) What is the equilibrium constant for the reaction? (b) Is the reaction exothermic or endothermic? (c) What will be the effect of raising the temperature on the rate constants and the equilibrium constant?

Catalysis

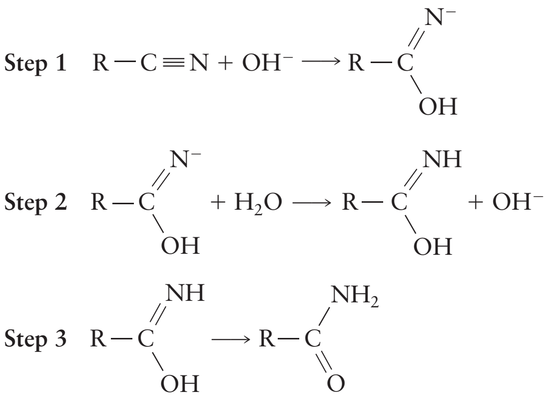
14.67 The presence of a catalyst provides a reaction pathway in which the activation energy of a certain reaction is reduced from $125\ kJ{\cdot}mol^{-1}$ to $75\ kJ{\cdot}mol^{-1}$. (a) By what factor does the rate of the reaction increase at 298 K, all other factors being equal? (b) By what factor would the rate change if the reaction were carried out at 350. K instead?

14.68 The presence of a catalyst provides a reaction pathway in which the activation energy of a certain reaction is reduced from $88\ kJ{\cdot}mol^{-1}$ to $53\ kJ{\cdot}mol^{-1}$. (a) By what factor does the rate of the reaction increase at 300. K, all other factors being equal? (b) By what factor would the rate change if the reaction were carried out at 400. K instead?

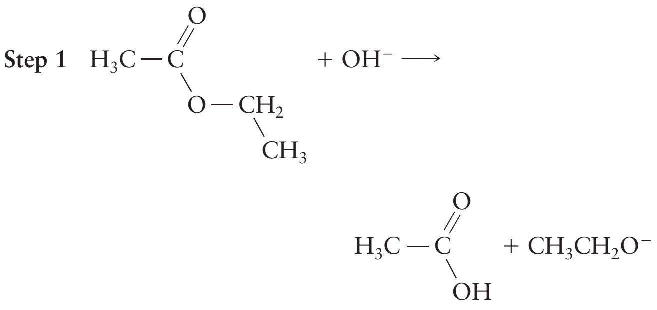
14.69 A reaction rate increases by a factor of 1000. in the presence of a catalyst at 25°C. The activation energy of the original pathway is $98\ kJ{\cdot}mol^{-1}$. What is the activation energy of the new pathway, all other factors being equal? In practice, the new pathway also has a different pre-exponential factor.

14.70 A reaction rate increases by a factor of 500. in the presence of a catalyst at 37°C. The activation energy of the original pathway is $106\ kJ{\cdot}mol^{-1}$. What is the activation energy of the new pathway, all other factors being equal? In practice, the new pathway also has a different pre-exponential factor.

14.71 The hydrolysis of an organic nitrile, a compound containing a —C≡N group, in basic solution, is proposed to proceed by the following mechanism. Write a complete balanced equation for the overall reaction, list any intermediates, and identify the catalyst in this reaction.



14.72 Consider the following mechanism for the hydrolysis of ethyl acetate. Write a complete balanced equation for the overall reaction, list any intermediates, and identify the catalyst in this reaction.



Step 2 $CH_3CH_2O^- + H_2O \longrightarrow CH_3CH_2OH + OH^-$

14.73 Determine which of the following statements about catalysts are true. If the statement is false, explain why. (a) In an equilibrium process, a catalyst increases the rate of the forward reaction but leaves the rate of the reverse reaction unchanged. (b) A catalyst is not consumed in the course of a reaction. (c) The pathway for a reaction is the same in the presence of a catalyst as in its absence, but the rate constants are decreased in both the forward and the reverse directions. (d) A catalyst must be carefully chosen to shift the equilibrium toward the products.

14.74 Determine which of the following statements about catalysts are true. If the statement is false, explain why. (a) A heterogeneous catalyst works by binding one or more of the molecules undergoing reaction to the surface of the catalyst. (b) Enzymes are naturally occurring proteins that serve as catalysts in biological systems. (c) The equilibrium constant for a reaction is greater in the presence of a catalyst. (d) A catalyst changes the pathway of a reaction in such a way that the reaction becomes more exothermic.

14.75 The Michaelis–Menten rate equation for enzyme reactions is typically written as the rate of formation of product (Eq. 19a). This equation implies that 1/Rate (where rate is the rate of formation of product) depends linearly on the inverse of the substrate concentration [S]. This relation allows K_M to be determined. Derive this equation and sketch 1/Rate against 1/[S]. Label the axes, the *y*-intercept, and the slope with their corresponding functions.

14.76 The Michaelis constant (K_M) is an index of the stability of an enzyme–substrate complex. Does a high Michaelis constant indicate a stable or an unstable enzyme–substrate complex? Explain your reasoning.

Integrated Exercises

14.77 Each of the following steps is an elementary reaction. Write its rate law and indicate its molecularity: (a) $NO + NO \longrightarrow N_2O_2$; (b) $Cl_2 \longrightarrow Cl + Cl$; (c) $NO_2 + NO_2 \longrightarrow NO + NO_3$; (d) Which of these reactions might be radical chain initiating?

14.78 Each of the following is an elementary reaction. Write its rate law and indicate its molecularity. (a) $O + CF_2Cl_2 \longrightarrow ClO + CF_2Cl$; (b) $OH + NO_2 + N_2 \longrightarrow HNO_3 + N_2$; (c) $ClO^- + H_2O \longrightarrow HClO + OH^-$; (d) Which of these reactions might be radical chain propagating?

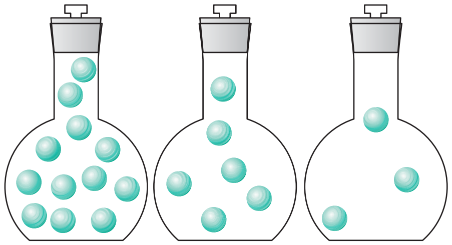
14.79 In some reactions, two or more different products can be formed by different pathways. If the product formed by the faster reaction predominates, the reaction is considered to be under kinetic control. If the predominant product is the more thermodynamically stable, the reaction is considered to be under thermodynamic control. In the reaction of HBr with the reactive intermediate $CH_3CH{=}CHCH_2^+$, at low temperatures the predominant product is $CH_3CHBrCH{=}CH_2$, but at high temperatures, the predominant product is $CH_3CH{=}CHCH_2Br$. (a) Which product is formed by the pathway with the larger activation energy? (b) Does kinetic control predominate at low or high temperatures? Explain your answers.

14.80 An organic compound A can decompose by either of two kinetically controlled pathways to form products B or C (see Exercise 14.79). The activation energy for the formation of B is greater than that for the formation of C. Will the ratio [B]/[C] increase or decrease as the temperature is increased? Explain your answer.

14.81 The equilibrium constant for the second-order attachment of a substrate to the active site of an enzyme was found to be 326 at 310 K. At the same temperature, the rate constant for the second-order attachment is $7.4 \times 10^7\ L\cdot mol^{-1}\cdot s^{-1}$. What is the rate constant for the loss of unreacted substrate from the active site (the reverse of the attachment reaction)?

14.82 Compounds A and B are unstable and each decomposes by a first-order process. At 398 K, the rate constant for the decomposition of A is $3.6 \times 10^{-5}\ s^{-1}$. Separate containers of A and B were prepared, with initial concentrations of 0.120 (mol A)$\cdot L^{-1}$ and 0.240 (mol B)$\cdot L^{-1}$. After 5.0 h, it was found that the concentration of A was three times the concentration of B. (a) What was the concentration of A at that time? (b) What is the rate constant for the decomposition of B at 398 K?

14.83 The first-order decomposition of compound X, a gas, is carried out and the data are represented in the following pictures. The green spheres represent the compound; the decomposition products are not shown. The times at which the images were taken are shown below each flask. (a) Determine the half-life of the reaction. (b) Draw the appearance of the molecular image at 8 s.



0 5.00 s 10.0 s

14.84 Determine the molecularity of the following elementary reactions:
(a) ○ + ●—● ⟶ ○—● + ●
(b) ○—○ ⟶ ○ + ○
(c) ○ + ○ + ● ⟶ ● + ○—○

14.85 The following rate laws were each derived from an elementary reaction. In each case, write the chemical equation for the reaction, determine its molecularity, and draw a proposed structure for the activated complex:
(a) Rate = $k[CH_3CHO]$ (Products are CH_3 and CHO.)
(b) Rate = $k[I]^2[Ar]$ (Products are I_2 and Ar; the role of the Ar is to remove energy as the product forms.)
(c) Rate = $k[O_2][NO]$ (Products are NO_2 and O.)

14.86 The half-life for the (first-order) decomposition of azomethane, $CH_3N{=}NCH_3$, in the reaction $CH_3N{=}NCH_3(g) \longrightarrow N_2(g) + C_2H_6(g)$ is 1.02 s at 300°C. A 45.0-mg sample of azomethane is placed in a 300.-mL reaction vessel and heated to 300°C. (a) What mass (in milligrams) of azomethane remains after 10. s? (b) Determine the partial pressure exerted by the $N_2(g)$ in the reaction vessel after 3.0 s.

14.87 All radioactive decay processes follow first-order kinetics. The half-life of the radioactive isotope tritium (^3H, or T) is 12.3 years. How much of a 25.0-mg sample of tritium would remain after 10.9 years?

14.88 The following mechanism has been proposed for the formation of hydrazine, $N_2(g) + 2\ H_2(g) \longrightarrow N_2H_4(g)$:

Step 1 $N_2 + H_2 \longrightarrow N_2H_2$

Step 2 $H_2 + N_2H_2 \longrightarrow N_2H_4$

The rate law for the reaction is Rate = $k[N_2][H_2]^2$. Which step is the slow step? Show your work.

14.89 The hydrolysis of sucrose ($C_{12}H_{22}O_{11}$) produces fructose and glucose: $C_{12}H_{22}O_{11}(aq) + H_2O(l) \longrightarrow C_6H_{12}O_6(\text{glucose, aq}) +$

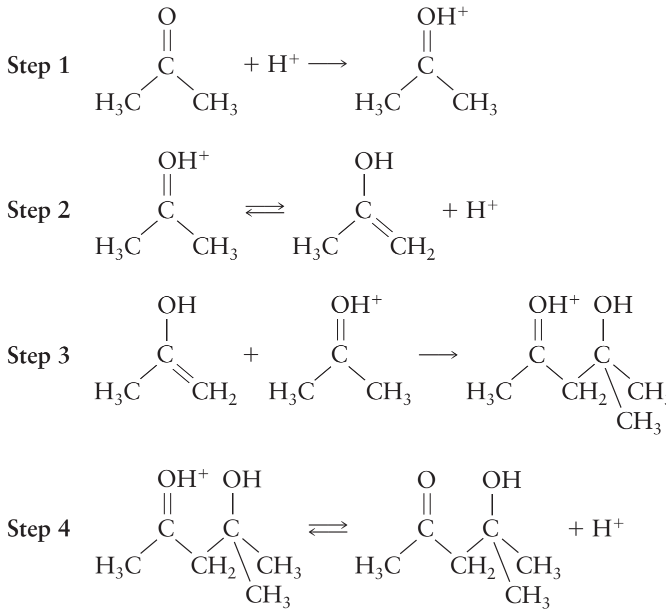
$C_6H_{12}O_6$(fructose, aq). Two mechanisms are proposed for this reaction.

(i) $C_{12}H_{22}O_{11} \longrightarrow C_6H_{12}O_6 + C_6H_{10}O_5$ (slow)
$C_6H_{10}O_5 + H_2O \longrightarrow C_6H_{12}O_6$ (fast)

(ii) $C_{12}H_{22}O_{11} + H_2O \longrightarrow C_6H_{12}O_6 + C_6H_{12}O_6$ (slow)

Under what conditions can these two mechanisms be distinguished by using kinetic data?

14.90 Ketones can react with themselves in a process known as *aldol condensation*. The mechanism for this reaction in acidic solution is shown here. Write the overall reaction, identify any intermediates, and determine the role of the hydrogen ion.



14.91 The rate law of the reaction $2\ NO(g) + 2\ H_2(g) \longrightarrow N_2(g) + 2\ H_2O(g)$ is Rate $= k[NO]^2[H_2]$, and the mechanism that has been proposed is

Step 1 $NO + NO \longrightarrow N_2O_2$

Step 2 $N_2O_2 + H_2 \longrightarrow N_2O + H_2O$

Step 3 $N_2O + H_2 \longrightarrow N_2 + H_2O$

(a) Which step in the mechanism is likely to be rate determining? Explain your answer. (b) Sketch a reaction profile for the overall reaction, which is known to be exothermic. Label the activation energies of each step and the overall reaction enthalpy.

14.92 (a) Using a graphing calculator or graphing software, such as that on the Web site for this book, calculate the activation energy for the acid hydrolysis of sucrose to give glucose and fructose from an Arrhenius plot of the data shown here. (b) Calculate the rate constant at 37°C (body temperature). (c) From data in Appendix 2A, calculate the enthalpy change for this reaction, assuming that the solvation enthalpies of the sugars are negligible. Draw an energy profile for the overall process.

Temperature (°C)	k (s^{-1})
24	4.8×10^{-3}
28	7.8×10^{-3}
32	13×10^{-3}
36	$20. \times 10^{-3}$
40.	32×10^{-3}

14.93 Raw milk sours in about 4 h at 28°C but in about 48 h in a refrigerator at 5°C. What is the activation energy for the souring of milk?

14.94 (a) From the following mechanism, derive Eq. 19a, which Michaelis and Menten proposed to represent the rate of formation of products in an enzyme-catalyzed reaction. (b) Show that the rate is independent of substrate concentration at high concentrations of substrate.

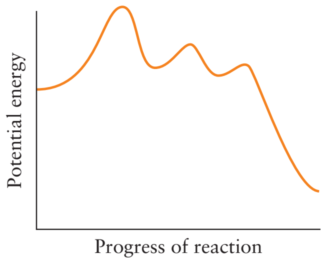
$$E + S \rightleftharpoons ES \quad k_1, k_1'$$
$$ES \longrightarrow E + P \quad k_2$$

where E is the free enzyme, S is the substrate, ES is the enzyme–substrate complex, and P is the product. Note that the steady-state concentration of free enzyme will be equal to the initial concentration of the enzyme less the amount of enzyme that is present in the enzyme–substrate complex: $[E] = [E]_0 - [ES]$.

14.95 For the enzyme-catalyzed conversion of a certain substrate, $K_M = 0.038\ mol \cdot L^{-1}$ at 25°C. When the substrate concentration is $0.156\ mol \cdot L^{-1}$, the rate of the reaction is $1.21\ mmol \cdot L^{-1}s^{-1}$. The maximum rate of the conversion reaction is reached at high substrate concentrations (see Exercise 14.94). Calculate the maximum rate of this enzyme-catalyzed reaction.

14.96 A gas composed of molecules of diameter 0.5 nm takes part in a chemical reaction at 300. K and 1.0 atm with another gas (present in large excess) consisting of molecules of about the same size and mass to form a gas-phase product at 300. K. The activation energy for the reaction is $25\ kJ \cdot mol^{-1}$. Use collision theory to calculate the ratio of the reaction rate at 320. K to that at 300. K.

14.97 Refer to the illustration below. (a) How many steps does this reaction have? (b) Which is the rate-determining step in this reaction? (c) Which step is the fastest? (d) How many intermediates must form in the reaction? (e) A catalyst is added that accelerates the third step only. What effect, if any, will the catalyst have on the rate of the overall reaction?



14.98 The second-order reactions in Table 14.4 show wide variations in activation energy. In an activated complex, the reactant bonds are lengthened while the product bonds are beginning to form. Consider what bonds need to be stretched to form the activated complex for each reaction and use bond enthalpies (Sections 2.14, 2.15, and 7.20) to explain the differences in activation energies.

14.99 The following mechanism has been suggested to explain the contribution of chlorofluorocarbons to the destruction of the ozone layer:

Step 1 $O_3 + Cl \longrightarrow ClO + O_2$

Step 2 $ClO + O \longrightarrow Cl + O_2$

(a) What is the reaction intermediate and what is the catalyst? (b) Identify the radicals in the mechanism. (c) Identify the steps as initiating, propagating, or terminating. (d) Write a chain-terminating step for the reaction. (See Box 14.3.)

C **14.100** Models of population growth are analogous to chemical reaction rate equations. In the model developed by Malthus in 1798, the rate of change of the population N of Earth is dN/dt = births – deaths. The numbers of births and deaths are proportional to the population, with proportionality constants b and d. Derive the integrated rate law for population change. How well does it fit the approximate data for the population of Earth over time given below?

Year	1750	1825	1922	1960	1974	1987	2000
$N/10^9$	0.5	1	2	3	4	5	6

14.101 The half-life of a substance taking part in a third-order reaction A $\longrightarrow$ products is inversely proportional to the square of the initial concentration of A. How can this half-life be used to predict the time needed for the concentration to fall to (a) one-half; (b) one-fourth; (c) one-sixteenth of its initial value?

14.102 Suppose that a pollutant is entering the environment at a steady rate R and that, once there, its concentration decays by a first-order reaction. Derive an expression for (a) the concentration of the pollutant at equilibrium in terms of R and (b) the half-life of the pollutant species when $R = 0$.

14.103 Which of the following plots will be linear? (a) [A] against time for a reaction first order in A; (b) [A] against time for a reaction zero order in A; (c) ln[A] against time for a reaction first order in A; (d) 1/[A] against time for a reaction second order in A; (e) k against temperature; (f) initial rate against [A] for a reaction first order in A; (g) half-life against [A] for a reaction zero order in A; (h) half-life against [A] for a reaction second order in A.

14.104 The pre-equilibrium and the steady-state approximations are two different approaches to deriving a rate law from a proposed mechanism. For the following mechanism, determine the rate law (a) by the pre-equilibrium approximation and (b) by the steady-state approximation. (c) Under what conditions do the two methods give the same answer? (d) What will the rate laws become at high concentrations of Br^-?

$$CH_3OH + H^+ \rightleftharpoons CH_3OH_2^+ \text{ (fast equilibrium)}$$

$$CH_3OH_2^+ + Br^- \longrightarrow CH_3Br + H_2O \text{ (slow)}$$

14.105 (a) What is the overall reaction for the following mechanism?

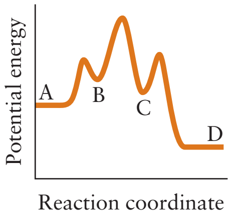
$$ClO^- + H_2O \rightleftharpoons HClO + OH^- \text{ (fast equilibrium)}$$

$$HClO + I^- \longrightarrow HIO + Cl^- \text{ (very slow)}$$

$$HIO + OH^- \rightleftharpoons IO^- + H_2O \text{ (fast equilibrium)}$$

(b) Write the rate law based on this mechanism. (c) How will the reaction rate depend on the pH of the solution? (d) How would the rate law differ if the reactions were carried out in an organic solvent?

14.106 The following schematic reaction profile is for the reaction A $\longrightarrow$ D. (a) Is the overall reaction exothermic or endothermic? Explain your answer. (b) How many intermediates are there? Identify them. (c) Identify each activated complex and reaction intermediate. (d) Which step is rate determining? Explain your answer. (e) Which step is the fastest? Explain your answer.



C **14.107** The decomposition of A has the rate law Rate = $k[A]^a$. Show that for this reaction the ratio $t_{1/2}/t_{3/4}$, where $t_{1/2}$ is the half-life and $t_{3/4}$ is the time for the concentration of A to decrease to $\frac{3}{4}$ of its initial concentration, can be written as a function of a alone and can therefore be used to make a quick assessment of the order of the reaction in A.

14.108 To prepare a 15-kg dog for surgery, 150 mg of the anesthetic phenobarbitol is administered intravenously. The reaction in which the anesthetic is metabolized (decomposed in the body) is first order in phenobarbitol and has a half-life of 4.5 h. After about 2 hours, the drug begins to lose its effect. However, the surgical procedure requires more time than had been anticipated. What mass of phenobarbitol must be re-injected to restore the original level of the anesthetic in the dog?

Chemistry Connections

14.109 Cyanomethane, commonly known as acetonitrile, CH_3CN, is a toxic volatile liquid that is used as a solvent to purify steriods and to extract fatty acids from fish oils. Acetonitrile can be synthesized from methyl isonitrile by the isomerization reaction $CH_3NC(g) \longrightarrow CH_3CN(g)$.

(a) Draw the Lewis structures of methyl isonitrile and cyanomethane; assign a hybridization scheme to each C atom and indicate whether each molecule is polar or nonpolar.
(b) Estimate $\Delta H°$ for the isomerization reaction by using the mean bond enthalpies in Table 7.8. Which isomer is the more stable?
(c) The isomerization reaction obeys the first-order rate law, Rate = $k[CH_3NC]$ in the presence of argon. The activation energy for this reaction is 161 $kJ\cdot mol^{-1}$ and the rate constant at 500. K is $6.6 \times 10^{-4}\ s^{-1}$. Calculate the rate constant at 300. K and the time (in seconds) needed for the concentration of CH_3NC to decrease to 75% of its initial value at 300. K.
(d) Draw a reaction profile for the isomerization reaction.
(e) Calculate the temperature at which the concentration of CH_3NC will decrease to 75% of its original concentration in 1.0 h.
(f) What purpose does the excess argon in part (c) serve?
(g) At low concentrations of Ar, the rate is no longer first order in $[CH_3NC]$; suggest an explanation.

Computers have had an enormous impact on the practice of chemistry, where they are used to control apparatus, record and manipulate data, and explore the structures and properties of atoms and molecules. Computer modeling is applied to solids as well as to individual molecules and is useful for predicting the behavior of a material, for example, for indicating which crystal structure of a compound is energetically most favorable, and for predicting phase changes. In this section we concentrate on the use of computers in the exploration of molecular structure. In this context, they are used both to explore practical problems such as predicting the pharmacological activity of compounds and to achieve a deep understanding of the changes that take place during chemical reactions.

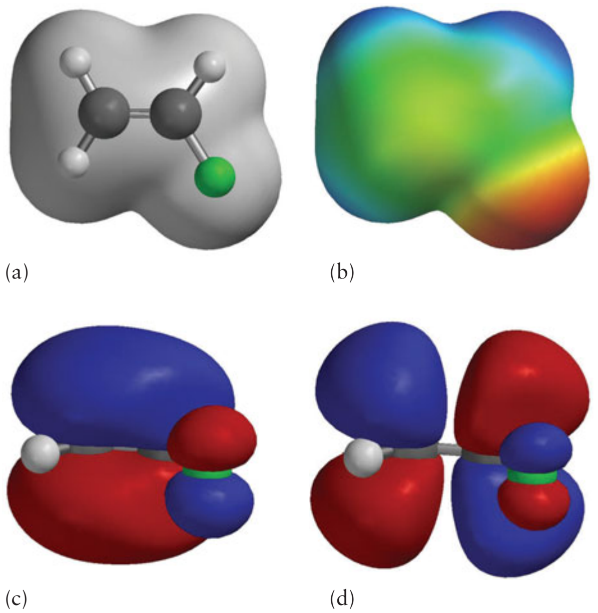
In *semi-empirical methods*, complicated integrals are set equal to parameters that provide the best fit to experimental data, such as enthalpies of formation. Semi-empirical methods are applicable to a wide range of molecules with a virtually limitless number of atoms, and are widely popular. The quality of results is very dependent on using a reasonable set of experimental parameters that have the same values across structures, and so this kind of calculation has been very successful in organic chemistry, where there are just a few different elements and molecular geometries.

In the more fundamental *ab initio methods*, an attempt is made to calculate structures from first principles, using only the atomic numbers of the atoms present and their general arrangement in space. Such an approach is intrinsically more reliable than a semi-empirical procedure but it is much more demanding computationally.

A currently popular alternative to the *ab initio* method is *density functional theory*, in which the energy is expressed in terms of the electron density rather than the wavefunction itself. The advantage of this approach is that it is less demanding computationally, requires less computer time, and in some cases—particularly for d-metal complexes—gives better agreement with experimental values than other procedures.

The raw output of a molecular structure calculation is a list of the coefficients of the atomic orbitals in each LCAO (linear combination of atomic orbitals) molecular orbital and the energies of the orbitals. The software commonly calculates dipole moments too. Various graphical representations are used to simplify the interpretation of the coefficients. Thus, a typical graphical representation of a molecular orbital uses stylized shapes (spheres for s-orbitals, for instance) to represent the basis set and then scales their size to indicate the value of the coefficient in the LCAO. Different signs of the wavefunctions are typically represented by different colors. The total electron density at any point (the sum of the squares of the occupied wavefunctions evaluated at that point) is commonly represented by an isodensity surface, a surface of constant total electron density.

An important aspect of a molecule, in addition to its geometrical shape and the energies of its orbitals, is the distribution of charge over its surface, because the charge distribution can strongly influence how one molecule (such as a potential drug) can attach to another (and dock into the active site of an enzyme, for instance). A common procedure begins with a calculation of the electrical potential at each point on an isodensity surface. The net potential is determined by subtracting the potential due to the electron density at that point from the potential due to the nuclei. The result is an *electrostatic potential surface* (an "elpot surface") in which net positive potential is shown in one color and net negative potential is shown in another, with intermediate gradations of color. The software can also depict a *solvent-accessible surface*, which represents the shape of the molecule by imagining a sphere representing a solvent molecule rolling across the surface and plotting the locations of its center.



Some graphical representations of fluoroethene, CH_2=CHF: (a) the isodensity surface showing the general shape of the molecule, (b) the electrostatic potential surface showing the relatively negatively charged region (denoted red) close to the fluorine atom, (c) the highest-energy occupied molecular orbital showing the π-bond between the two carbon atoms and the partial involvement of a fluorine orbital, (d) the lowest-energy unoccupied orbital, which is the antibonding counterpart of the π-orbital.

Procedures are now available that allow for the presence of several solvent molecules around a solute molecule. This approach takes into account the effect of molecular interactions with the solvent on properties such as the enthalpy of formation and the shape adopted by a nonrigid molecule, such as a protein or a region of DNA. These studies are important for investigating the structures and reactions of biological molecules in their natural environment.

What Are the Key Ideas? The structures of atoms determine their properties; consequently, the behavior of elements is related to their locations in the periodic table.

Why Do We Need to Know This Material? Knowledge of the family relationships of the elements helps us comprehend the nature of matter and allows us to design new materials. The elements in the first four main groups include carbon, the central element of life; silicon and germanium, which are used to create artificial intelligence; calcium, which is responsible for the rigidity of our bones and teeth; the space-age metals aluminum and beryllium; the alkali metals; and hydrogen, the fuel of the stars—and perhaps our future energy source on Earth. The elements in the last four groups of the periodic table include some that are vital to life, such as the nitrogen of proteins, the oxygen of the air, and the phosphorus of our bones, and so a familiarity with their properties helps us to understand living systems.

What Do We Need to Know Already? The information in this chapter is organized around the principles of atomic structure and specifically the periodic table (Chapter 1). However, the chapter draws on all the preceding chapters, because it uses those principles to account for the properties of the elements.

This chapter and the next survey the properties of the elements and their compounds in relation to their locations in the periodic table. To prepare for this journey through the periodic table, we first review the trends in properties discussed in earlier chapters. We then start with the unique element hydrogen and move on to the elements of the main groups, working from left to right across the table. The same principles apply to the elements of the d- and f-blocks, but those elements have some unique characteristics (mainly their wide variety of oxidation states and their ability to act as Lewis acids), and so they are treated separately in Chapter 16.

Although we concentrate on periodic trends, we also need to know details such as where specific elements are found in nature and how they are purified. In part, the usefulness and availability of an element reflects its abundance on Earth and specifically in the Earth's crust, which may be quite different from its cosmic abundance. Figure 15.1 summarizes the abundances of the elements in three settings: the universe as a whole, the Earth's crust, and the human body.

PERIODIC TRENDS

In Chapter 1, we saw that the members of each group have analogous valence-shell electron configurations, which give them similar properties. However, the element at the head of a group often has features that distinguish it from its **congeners,** the other members of the group. In these introductory sections, we review atomic properties that correlate with the position of an element in the periodic table. Then we investigate periodic trends in bonding by comparing examples of two types of compounds—hydrides and oxides.

15.1 Atomic Properties

All the elements in a given main group have in common a characteristic valence electron configuration. The electron configuration controls the number of bonds that an atom of the element can form and affects its chemical and physical properties. Five atomic properties are principally responsible for the characteristic properties of each

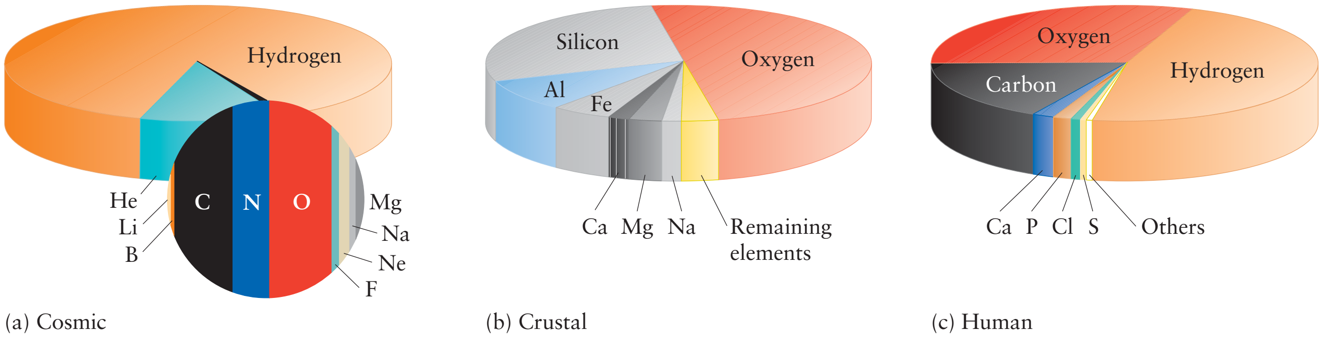

FIGURE 15.1 These charts show the relative abundances of the principal elements in (a) the universe (the "cosmic abundances"); (b) the crust of the Earth; and (c) the human body.

element: atomic radius, ionization energy, electron affinity, electronegativity, and polarizability. All five properties are related to trends in the effective nuclear charge experienced by the valence electrons and their distance from the nucleus.

As we saw in Section 1.12 and Fig. 1.45, valence electrons experience increasing effective nuclear charge on going across a period from left to right. The attraction of a valence electron to the nucleus weakens sharply when electrons enter a new shell, because valence electrons belong to shells that are successively farther from the nucleus and surround electron-rich cores. The valence electrons of elements in the upper right of the periodic table, near fluorine, experience the greatest attraction to their nuclei and those of elements in the lower left, near cesium, experience the least. As a result:

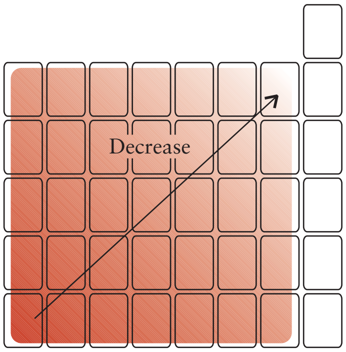

FIGURE 15.2 Atomic radius tends to decrease from left to right across a period and to increase down a group. This diagram and those in Figs. 15.3 through 15.5 are highly schematic representations of periodic trends, with the density of the red tint representing the value of the property: the denser the tint, the higher the value.

- Atomic radii typically decrease from left to right across a period and increase down a group (Fig. 15.2; see also Figs. 1.46 and 1.47).

As the nuclear charge experienced by the valence electrons increases across a period, the electrons are pulled closer to the nucleus, so decreasing the atomic radius. Down a group the valence electrons are progressively farther from the nucleus, which increases the atomic radius. Ionic radii follow similar periodic trends (see Fig. 1.48).

- First ionization energies typically increase from left to right across a period and decrease down a group (Fig. 15.3; see also Figs. 1.50 and 1.51).

The increase from left to right across a period is due to the increasing effective nuclear charge, which grips the electrons more tightly. The decrease in ionization energy down a group shows that it is easier to remove valence electrons from shells that are farther from the nucleus and hence shielded by a greater number of core electrons.

- The highest electron affinities are found at the top right of the periodic table (see Fig. 1.54; the trends are too ill defined to depict simply).

The electron affinity of an element is a measure of the energy released when an anion is formed. Except for the noble gases, elements near fluorine have the highest electron affinities, and so we can expect them to be present as anions in compounds with metallic elements. Once again, we see the effect of increasing effective nuclear charge: more energy is released when electrons attach to atoms in which they experience the higher effective nuclear charge.

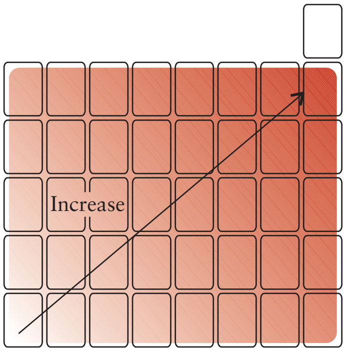

FIGURE 15.3 Ionization energy tends to increase from left to right across a period and to decrease down a group.

- Electronegativities typically increase from left to right across a period and decrease down a group (Fig. 15.4; see also Fig. 2.12).

The greater the effective nuclear charge and the closer the electrons are to the nucleus, the stronger the pull on the electrons in a bond. The electronegativity of an element—a measure of the tendency of an atom to attract electrons to itself when part of a compound—is a useful guide to the type of bond that the element is likely to form. When there is a large difference in electronegativity between two elements, their

atoms form ionic bonds with each other; when the difference is small, the bonds are covalent.

- Polarizabilities typically decrease from left to right along a period and increase down a group (Fig. 15.5).

Polarizability measures the ease with which an electron cloud can be distorted and is greatest for the electron-rich heavier atoms of a group and for negatively charged ions. On the other hand, high polarizing power—the ability to distort the electron cloud of a neighboring atom or ion—is commonly associated with small size and high positive charge. We saw in Section 2.13 that a highly polarizable atom or ion (such as iodine or the iodide ion) in combination with an atom or ion of high polarizing power (such as beryllium) is likely to have considerable covalent character in its bonds.

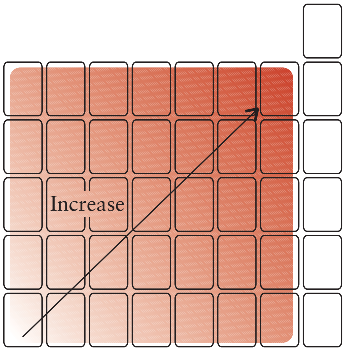

FIGURE 15.4 Electronegativity generally increases from left to right across a period and decreases down a group.

Self-Test 15.1A Which of the elements carbon, aluminum, and germanium has atoms with the greatest polarizability?

[*Answer:* Germanium]

Self-Test 15.1B Which of the elements oxygen, gallium, and tellurium has the greatest electron affinity?

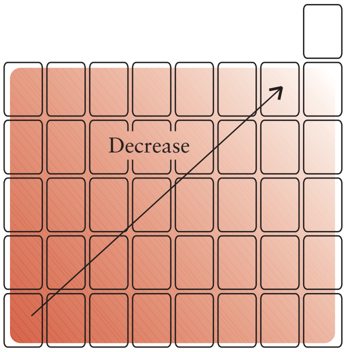

FIGURE 15.5 The polarizability of atoms tends to decrease from left to right across a period and to increase down a group.

Atomic radii decrease from left to right across a period and increase down a group; ionization energies increase across a period and decrease down a group; electron affinities and electronegativities are highest near fluorine; polarizabilities decrease from left to right across a period and increase down a group.

15.2 Bonding Trends

The number of bonds an element can form (its "valence") and their type are related to its position in the periodic table. We can usually predict the valence of an element in Period 2 from the number of electrons in the valence shell and the octet rule. For example, carbon, with four valence electrons, commonly forms four bonds; and oxygen, with six valence electrons and therefore needing two more to complete its octet, typically forms two bonds. Elements in Period 3 and higher periods can have higher valences than the octet rule suggests. These elements have access to empty d-orbitals and can use them to expand their valence shells past the usual octet of electrons, or they simply have atoms large enough to bond to more neighbors. Elements at the foot and toward the left of the p-block also have variable valence: they can display the inert-pair effect and have an oxidation number 2 less than their group number suggests (Section 1.19).

The radius of an atom helps to determine how many other atoms can bond to it. The small radii of Period 2 atoms, for instance, are largely responsible for the differences between their properties and those of their congeners. As described in Section 2.10, one reason that small atoms typically have low valences is that so few other atoms can pack around them. Nitrogen, for instance, never forms pentahalides, but phosphorus does. With few exceptions, only Period 2 elements form multiple bonds with themselves or other elements in the same period, because only they are small enough for their p-orbitals to have substantial π overlap (Fig. 15.6).

(a)

(b)

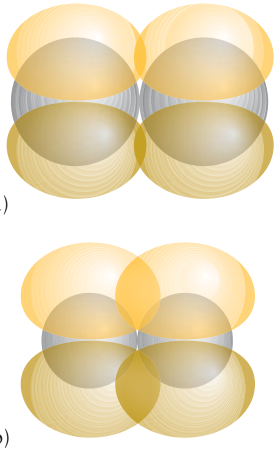

FIGURE 15.6 (a) The p-orbitals of Period 3 and heavier elements are held apart by the cores of the atoms (shown in gray) and have very little overlap with each other. (b) In contrast, the atoms of elements in Period 2 are small; consequently their p-orbitals can overlap effectively with each other and with those of elements in later periods.

Periodic trends in bonding for main-group elements become apparent when we compare the binary compounds that they form with specific elements. All the main-group elements, with the exception of the noble gases and, possibly, indium and thallium, form binary compounds with hydrogen, so we can examine hydrides to look for periodic trends (Section 15.4). The formulas of hydrides of main-group elements are related directly to the group number and reveal the typical valences of the elements (Fig. 15.7):

Group:	Group 14/IV	Group 15/V	Group 16/VI	Group 17/VII
Element:	C	N	O	F
Hydride:	CH_4	NH_3	H_2O	HF
Valence:	4	3	2	1

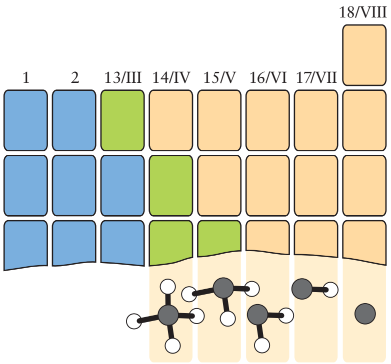

FIGURE 15.7 The chemical formulas of the hydrides of the elements of the main groups display the valence characteristic of each group.

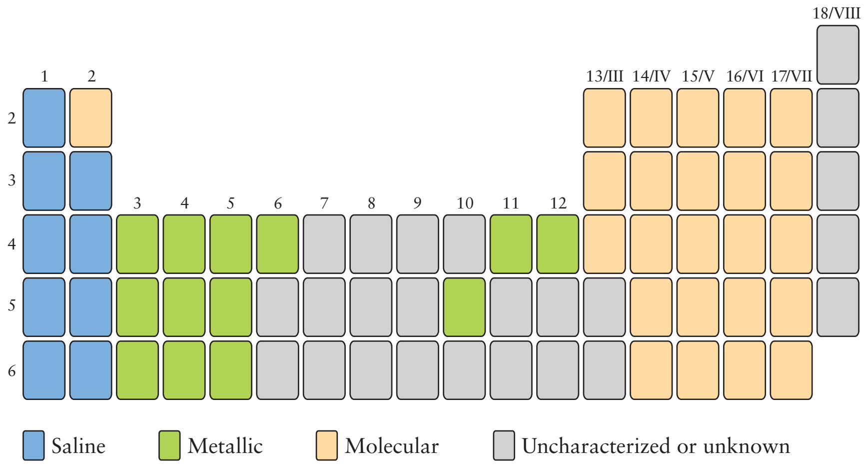

FIGURE 15.8 The different classes of binary hydrogen compounds and their distribution throughout the periodic table.

The nature of a binary hydride is related to the characteristics of the element bonded to hydrogen (Fig. 15.8). Strongly electropositive metallic elements form ionic compounds with hydrogen in which the latter is present as a hydride ion, H^-. These ionic compounds are called *saline hydrides* (or saltlike hydrides). They are formed by all members of the s-block, with the exception of beryllium, and are made by heating the metal in hydrogen:

$$2\,K(s) + H_2(g) \xrightarrow{\Delta} 2\,KH(s)$$

The saline hydrides are white, high-melting-point solids with crystal structures that resemble those of the corresponding halides. The alkali metal hydrides, for instance, have the rock-salt structure (Fig. 5.41).

The *metallic hydrides* are black, powdery, electrically conducting solids formed by heating certain of the d-block metals in hydrogen (Fig. 15.9):

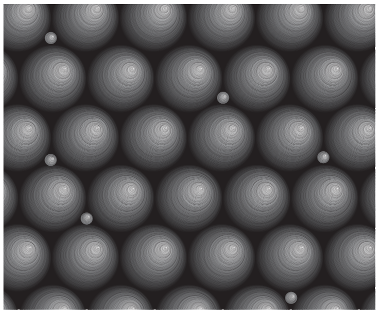

FIGURE 15.9 In a metallic hydride, the tiny hydrogen atoms (the small spheres) occupy gaps—called *interstices*—between the larger metal atoms (the large spheres).

$$2\,Cu(s) + H_2(g) \xrightarrow{\Delta} 2\,CuH(s)$$

Because the metallic hydrides release their hydrogen (as H_2 gas) when heated or treated with acid, they are being investigated for storing and transporting hydrogen. Both saline and metallic hydrides have the high enthalpy densities (enthalpies of combustion per liter) desirable in a portable fuel.

Nonmetals form covalent *molecular hydrides*, which consist of discrete molecules. These compounds are volatile and many are Brønsted acids. Some are gases—for example, ammonia, the hydrogen halides (HF, HCl, HBr, HI), and the lighter hydrocarbons such as methane, ethane, ethene, and ethyne. Liquid molecular hydrides include water and hydrocarbons such as octane and benzene.

Broadly speaking (that is, there are exceptions), the pattern of hydrides to note is:

Block:	**s-block**	**d-block**	**p-block**
Type:	saline	metallic	molecular

Xenon forms an oxide, but by an indirect route.

All the main-group elements except the noble gases also react with oxygen. Like hydrides, the resulting oxides also reveal periodic trends in the elements. The trend in bonding type is from soluble ionic oxides on the left of the periodic table, through insoluble, high-melting-point oxides on the left of the p block, to low-melting-point and often gaseous molecular oxides on the right. Metallic elements with low ionization energies commonly form basic ionic oxides. Elements with intermediate ionization energies, such as beryllium, boron, aluminum, and the metalloids, form *amphoteric* oxides (react with both acids and bases) that do not react with or dissolve in water, but do dissolve in both acidic and basic solutions.

Many oxides of nonmetals are gaseous molecular compounds, such as CO_2, NO, and SO_3. Most can act as Lewis acids, because the electronegative oxygen atoms withdraw

electrons from the central atom, enabling it to act as an electron pair acceptor. Oxides of nonmetals that react with water typically form acidic solutions and hence are called **acid anhydrides.** The familiar laboratory acids HNO_3 and H_2SO_4, for instance, are derived from the anhydrides N_2O_5 and SO_3, respectively. Even oxides that do not react with water can be regarded as the *formal* anhydrides of acids. A **formal anhydride** of an acid is the molecule obtained by striking out the elements of water (H, H, and O) from the molecular formula of the acid. Carbon monoxide, for instance, is the formal anhydride of formic acid, HCOOH, although CO does not react with cold water to form the acid.

The general pattern of oxides to keep in mind is:

Block:	**s-block**	**d-block**	**p-block**
Type:	ionic	ionic	covalent
Acid–base character	basic	basic to amphoteric	amphoteric to acidic

Self-Test 15.2A An element ("E") in Period 4 forms a molecular hydride with the formula HE. Identify the element.

[***Answer:*** Bromine]

Self-Test 15.2B An element ("E") in Period 3 forms an amphoteric oxide with the formula E_2O_3. Identify the element.

Valence and oxidation state are directly related to the valence-shell electron configuration of a group. Binary hydrides are classified as saline, metallic, or molecular. Oxides of metals tend to be ionic and to form basic solutions in water. Oxides of nonmetals are molecular and many are the anhydrides of acids.

HYDROGEN

Hydrogen is widely considered to be the fuel of our future, and so its properties are of great interest to scientists and engineers. It occupies a unique place in the periodic table. Although a hydrogen atom has the same valence electron configuration as atoms of the Group 1 elements, ns^1, and forms +1 ions, the element has few other similarities to the alkali metals. Hydrogen is a nonmetal that resembles the halogens: it needs only one electron to complete its valence electron configuration, it can form −1 ions, and it exists as diatomic molecules (H_2). However, the chemical properties of hydrogen are very different from those of the halogens. Because it does not fit clearly into either group of elements, we do not assign it to a group.

Be aware, though, that most periodic tables that you will come across assign hydrogen either to Group 1 or (less commonly) to both Group 1 and Group 17/VII.

15.3 The Element

Hydrogen is the most abundant element in the universe, accounting for 89% of all atoms (see Fig. 15.1). These atoms were formed in the first few seconds after the Big Bang, the event that marked the beginning of the universe. However, there is little free hydrogen on Earth because H_2 molecules, being very light, move at such high average speeds that they escape from the Earth's gravity. It takes heavier atoms to anchor hydrogen to the planet in compounds. Most of the Earth's hydrogen is present as water, either in the oceans or trapped inside minerals and clays. Hydrogen is also found in the hydrocarbons that make up the **fossil fuels:** coal, petroleum, and natural gas. It takes energy to release hydrogen from these compounds and one of the challenges to achieving its potential as a fuel is to produce the gas by a means that takes less energy than can be obtained from burning it.

Because water is its only combustion product, hydrogen burns without polluting the air or contributing significantly to the greenhouse effect (Box 15.1). Petroleum, coal, and natural gas are becoming increasingly rare, but there is enough water in the oceans to generate all the hydrogen fuel we shall ever need. Hydrogen is obtained from water by electrolysis, but that process requires electricity that has been generated elsewhere. Chemists are currently seeking ways of using sunlight to drive the *water-splitting reaction*, the photochemical decomposition of water into its elements:

In the United States, so many vehicles operate on hydrogen fuel cells (see Box 13.1) that hydrogen refueling stations have opened in many cities, including Washington, DC.

$$\text{Water-splitting reaction: } 2\,H_2O(l) \xrightarrow{\text{light}} 2\,H_2(g) + O_2(g) \qquad \Delta G^\circ = +474\text{ kJ}$$

BOX 15.1 WHAT HAS THIS TO DO WITH . . . THE ENVIRONMENT?

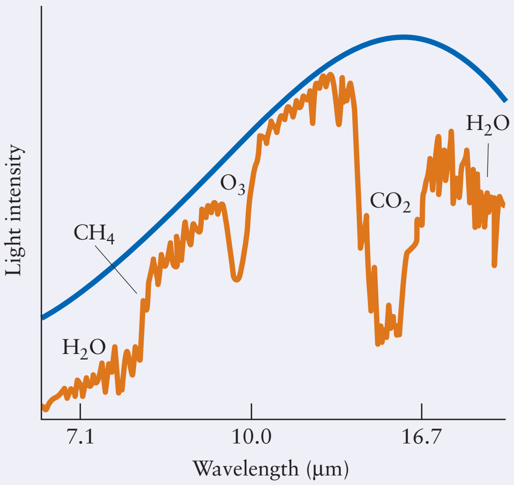
The Greenhouse Effect

Every year our planet receives from the Sun more than enough radiant energy to supply all our energy needs. About 55% of solar radiation is reflected away or used in natural processes. The remaining 45% is converted into thermal motion (heat), most of which escapes as infrared radiation with wavelengths between 4 and 50 μm.

The *greenhouse effect* is the trapping of this infrared radiation by certain gases in the atmosphere. This effect warms the Earth, as if the entire planet were enclosed in a huge greenhouse.[1] Oxygen and nitrogen, which make up roughly 99% of the atmosphere, do not absorb infrared radiation. However, water vapor and CO_2 do. Even though these two gases make up only about 1% of the atmosphere, they trap enough radiation to raise the temperature of the Earth by 33°C. Without this naturally occurring greenhouse effect, the average surface temperature of the Earth would be well below the freezing point of water.

The major greenhouse gases include water vapor, carbon dioxide, methane, dinitrogen oxide (nitrous oxide), ozone, and certain chlorofluorocarbons. Water is the most important greenhouse gas. It absorbs strongly near 6.3 μm and at wavelengths longer than 12 μm, as shown on the plot. The carbon dioxide in the atmosphere absorbs about half the infrared radiation with wavelengths of 14–16 μm (see graph).

The concentration of water vapor in the atmosphere is thought to have remained steady over time, but concentrations of some other greenhouse gases are rising. From the year 1000 or earlier until about 1750, the CO_2 concentration in the atmosphere remained fairly stable at about 280 ± 10 parts per million by volume (ppmv). Since then, the CO_2 concentration has increased to 379 ppmv in 2005 (see the second graph). The concentration of methane, CH_4, has more than doubled during this time and is now at its highest level in 160 000 years. Studies of air pockets in ice cores taken from Antarctica show that changes in the concentrations of both atmospheric carbon dioxide and methane over the past 160 000 years correlate well with changes in the global surface temperature. The rising



The intensity of infrared radiation at various wavelengths that would be lost from Earth in the absence of greenhouse gases is shown by the smooth line. The jagged line is the intensity of the radiation actually emitted. The maximum wavelength of radiation absorbed by each greenhouse gas is indicated.

concentrations of carbon dioxide and methane are therefore of some concern.

Where is the additional CO_2 coming from? Human activities are responsible. Some is generated when limestone, $CaCO_3$, is heated and decomposed in cement making (see Section 6.8). Large amounts of CO_2 are also released to the atmosphere by deforestation, which involves burning large areas of brush and trees. However, most of it comes from the burning of fossil fuels, which began on a large scale after 1850 and increased by about 80% from 1970 to 2004. The additional methane is coming mainly from the petroleum industry and from agriculture.

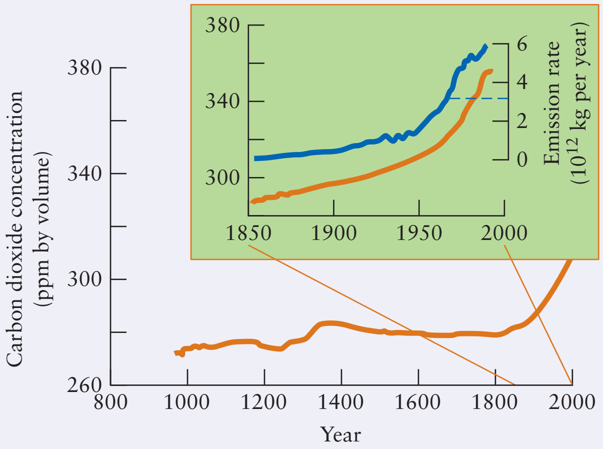
The temperature of the surface of the Earth is rising about 0.2°C per decade (see graph). If current trends in population growth and energy use continue, by the middle of the twenty-first century the concentration of CO_2 in the atmosphere will be about twice its value prior to the Industrial Revolution. What are the likely consequences of this doubling of the CO_2 concentration?

[1] The actual insulation mechanism is different in a greenhouse. The glass not only inhibits the escape of infrared radiation but also keeps the warm air inside.

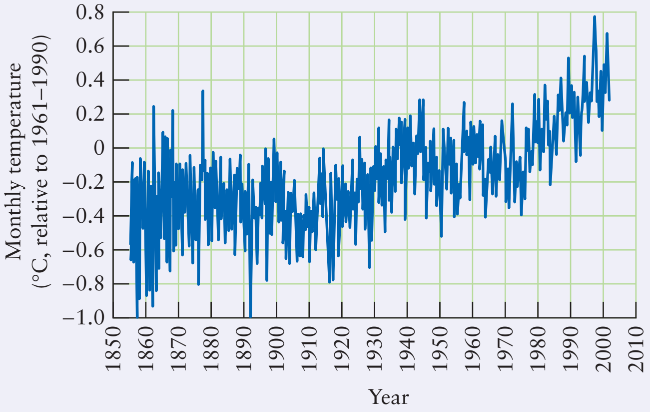
At present, most commercial hydrogen is obtained as a by-product of petroleum refining in a sequence of two catalyzed reactions. The first is a *reforming reaction*, in which a hydrocarbon and steam are converted into carbon monoxide and hydrogen over a nickel catalyst:

$$\text{Reforming reaction: } CH_4(g) + H_2O(g) \xrightarrow{Ni} CO(g) + 3\,H_2(g)$$

The mixture of products, called *synthesis gas*, is the starting point for the manufacture of many other compounds, including methanol. The reforming reaction is followed by



Concentration of carbon dioxide in the atmosphere, over the past 1000 years as determined from ice-core measurements. The blue line shows the emission of CO_2.



The average change in surface temperature of the Earth from 1855 to 2002 compared to the average temperature during 1961–1990.

The Intergovernmental Panel on Climate Change (IPCC) estimated in 2001 that, by the year 2100, the Earth will undergo an increase in temperature of 3°C, with a rise in sea level of about 0.5 m. A rise of 3°C may not sound like much. However, the temperature during the last ice age was only 6°C lower than at present. Furthermore, the *rate* of temperature change is likely to be faster than at any time in the past 10 000 years. Rapid climate changes may bring about droughts and storms and have detrimental effects on many of the Earth's ecosystems.

Computer projections of atmospheric CO_2 concentration for the next 200 years predict escalating increases in CO_2 concentration. Only about half the CO_2 released by humans is absorbed by Earth's natural systems. The other half increases the CO_2 concentration in the atmosphere by about 1.5 ppmv per year. Two conclusions can be drawn from these facts. First, even if CO_2 emissions were reduced to the amount emitted in 1990 and held constant at that level, the concentration of CO_2 in the atmosphere would continue to increase at about 1.5 ppmv per year for the next century. Second, to maintain CO_2 at its current concentration of 360 ppmv, we would have to reduce fossil fuel consumption by about 50% immediately.

Alternatives to fossil fuels, such as hydrogen, are explored in Box 7.2 and Section 15.3. Coal, which is mostly carbon, can be converted into fuels with a lower proportion of carbon. Its conversion into methane, CH_4, for instance, would reduce CO_2 emissions per unit of energy. We can also work with nature by accelerating the uptake of carbon by the natural processes of the carbon cycle. For example, one proposed solution is to pump CO_2 exhaust deep into the ocean, where it would dissolve to form carbonic acid and bicarbonate ions. Carbon dioxide can also be removed from power plant exhaust gases by passing the exhaust through an aqueous slurry of calcium silicate to produce harmless solid products:

$$2\,CO_2(g) + H_2O(l) + CaSiO_3(s) \longrightarrow SiO_2(s) + Ca(HCO_3)_2(s)$$

the *shift reaction*, in which the carbon monoxide in the synthesis gas reacts with more water:

$$\text{Shift reaction: } CO(g) + H_2O(g) \xrightarrow{Fe/Cu} CO_2(g) + H_2(g)$$

Hydrogen is prepared in small amounts in the laboratory by reducing hydrogen ions from a strong acid (such as hydrochloric acid) with a metal that has a negative standard potential, such as zinc:

$$Zn(s) + 2\,H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2(g)$$

TABLE 15.1 Physical Properties of Hydrogen

Valence configuration: $1s^1$
Normal form*: colorless, odorless gas

Z	Name	Symbol	Molar mass ($g \cdot mol^{-1}$)	Abundance (%)	Melting point (°C)	Boiling point (°C)	Density† ($g \cdot L^{-1}$)

*_Normal form_ means the state and appearance of the element at 25°C and 1 atm.
†At 25°C and 1 atm.

FIGURE 15.10 The two measuring cylinders contain the same mass of liquid. The cylinder on the left holds about 10 mL of water, that on the right liquid hydrogen at –253°C, which is one-tenth as dense and consequently has a volume of about 100 mL.

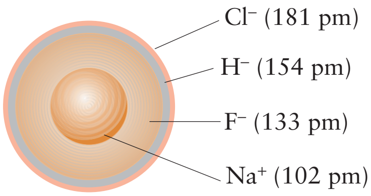
Hydrogen is a colorless, odorless, tasteless gas (Table 15.1). Because H_2 molecules are small and nonpolar, they can attract each other only by very weak London forces. As a result, hydrogen does not condense to a liquid until it is cooled to a very low temperature (20 K at 1 atm). One striking physical property of liquid hydrogen is its very low density ($0.070\ g \cdot cm^{-3}$), which is less than one-tenth that of water (Fig. 15.10). This low density makes hydrogen a very lightweight fuel. Hydrogen has the highest specific enthalpy of any known fuel (the highest enthalpy of combustion per gram), and so liquid hydrogen is used with liquid oxygen to power the space shuttle's main rocket engines.

Each year, about half the 0.3 Mt (3×10^8 kg) of hydrogen used in industry is converted into ammonia by the Haber process (Section 10.12). Through the reactions of ammonia, hydrogen finds its way into numerous other important nitrogen compounds such as hydrazine and sodium amide (see Section 15.16).

Hydrogen is produced as a by-product of the refining of fossil fuels and by electrolysis of water. It has a low density and weak intermolecular forces.

15.4 Compounds of Hydrogen

Hydrogen is unusual because it can form both a cation (H^+), so resembling the alkali metals, and an anion (H^-), so resembling the halogens. Moreover, its intermediate electronegativity (2.2 on the Pauling scale) means that it can also form covalent bonds with all the nonmetals and metalloids. Because hydrogen forms compounds with so many elements (Table 15.2; also see Section 15.2), we shall meet more of its compounds when we study the other elements.



1

The hydride ion, H^-, is large, with a radius of 154 pm (**1**), falling between the fluoride and chloride ions in size. The large radius of the ion makes it highly polarizable and contributes to covalent character in its bonds to cations. However, the single positive charge of the hydrogen atomic nucleus can barely manage to keep control over the two electrons in the H^- ion, and so they are easily lost. The low energy required for a hydride ion to lose an electron results in ionic hydrides being very powerful reducing agents, and $E°(H_2/H^-) = -2.25$ V. This value is similar to the standard potential for Na^+/Na ($E° = -2.71$ V) and, like sodium metal, hydride ions react with water as soon as they come into contact with it:

$$NaH(s) + H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$$

TABLE 15.2 Chemical Properties of Hydrogen

Reactant	Reaction with hydrogen
Group 1 metals (M)	$2\ M(s) + H_2(g) \longrightarrow 2\ MH(s)$
Group 2 metals (M, not Be or Mg)	$M(s) + H_2(g) \longrightarrow MH_2(s)$
some d-block metals (M)	$2\ M(s) + x\ H_2(g) \longrightarrow 2\ MH_x(s)$
oxygen	$O_2(g) + 2\ H_2(g) \longrightarrow 2\ H_2O(l)$
nitrogen	$N_2(g) + 3\ H_2(g) \longrightarrow 2\ NH_3(g)$
halogen (X_2)	$X_2(g,l,s) + H_2(g) \longrightarrow 2\ HX(g)$

Because this reaction produces hydrogen, saline hydrides are potentially useful as transportable sources of hydrogen fuel.

Compounds with a bond between hydrogen and nitrogen, oxygen, or fluorine—elements with small, highly electronegative atoms—participate in the very strong intermolecular force known as *hydrogen bonding* (Section 5.5). A hydrogen bond is about 5% as strong as a covalent bond between the same types of atoms but about ten times stronger than other intermolecular interactions. For example, the H—O bond enthalpy is 463 $kJ \cdot mol^{-1}$, whereas the O···H—O hydrogen bond enthalpy is about 20 $kJ \cdot mol^{-1}$. There are several models of hydrogen bonding (Chapter 5); the simplest is as a coulombic interaction between the partial positive charge on a hydrogen atom and the partial negative charge of another atom, as in $O^{\delta-} \cdots {}^{\delta+}H—O$.

Thinking point: Deuterium, ^{2}H, differs from ^{1}H only in the mass of its nucleus. Can you think of how that difference might affect its properties and those of its compounds?

Self-Test 15.3A What common binary compounds of hydrogen are powerful reducing agents?

[***Answer:*** The saline (ionic) hydrides]

Self-Test 15.3B What are some of the properties of hydrogen that argue against its classification as a Group 1 element?

The hydride ion has a large radius and is highly polarizable. Ionic hydrides are powerful reducing agents. Hydrogen can form hydrogen bonds to lone pairs of electrons on highly electronegative elements.

GROUP 1: THE ALKALI METALS

The members of Group 1 are called the *alkali metals*. The chemical properties of these elements are unique and strikingly similar. Nevertheless, there are differences, and the subtlety of some of these differences is the basis of the most subtle property of matter: consciousness. Our thinking, which relies on the transmission of signals along neurons, is achieved by the concerted action of sodium and potassium ions and their carefully regulated migration across membranes. So, even to learn about sodium and potassium, we have to make use of them in our brains.

As in the discussion of hydrogen, in this section we examine the properties of the alkali metals in the context of the periodic table and focus on significant applications of the elements and selected compounds. The valence electron configuration of the alkali metals is ns^1, where n is the period number. Their physical and chemical properties are dominated by the ease with which the single valence electron can be removed (Table 15.3)

TABLE 15.3 Group 1 Elements: The Alkali Metals

Valence configuration: ns^1
Normal form*: soft, silver-gray metals

Z	Name	Symbol	Molar mass ($g \cdot mol^{-1}$)	Melting point (°C)	Boiling point (°C)	Density ($g \cdot cm^{-3}$)
3	lithium	Li	6.94	181	1347	0.53

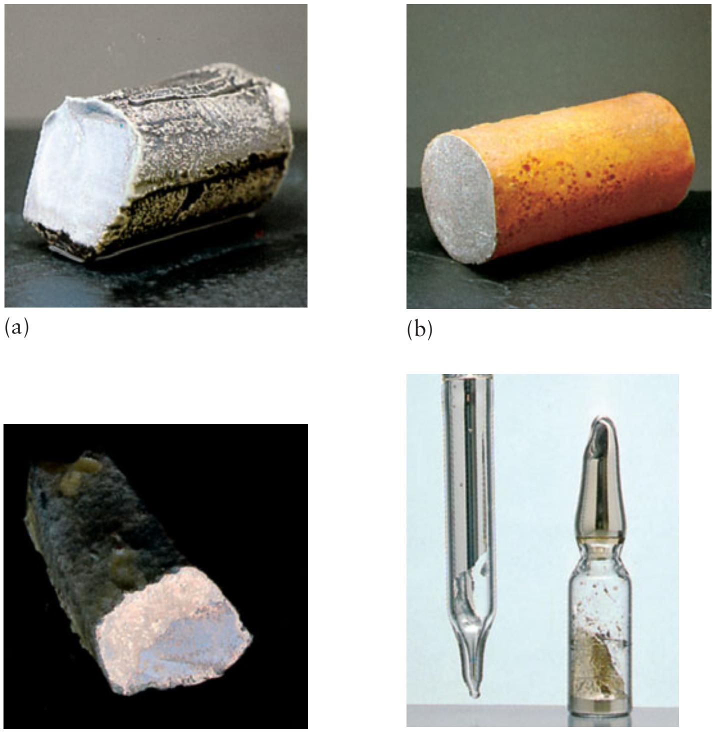
55	cesium	Cs	132.91	28	678	1.87
87	francium	Fr	(223)	27	677	—

**Normal form* means the state and appearance of the element at 25°C and 1 atm.



(a) (b) (c) (d)

FIGURE 15.11 The alkali metals of Group 1: (a) lithium; (b) sodium; (c) potassium; (d) rubidium and cesium. Francium has never been isolated in visible quantities. The first three elements were freshly cut and you can see how rapidly they have been corroded in moist air; rubidium and cesium are even more reactive and have to be stored (and photographed) in sealed, airless containers.

15.5 The Group 1 Elements

The alkali metals are the most violently reactive of all the metals. They are too easily oxidized to be found in the free state in nature and cannot be extracted from their compounds by ordinary chemical reducing agents. The metals are obtained by electrolysis of their molten salts, as in the electrolytic Downs process (Section 13.13) or, in the case of potassium, by exposing molten potassium chloride to sodium vapor:

$$\mathrm{KCl(l) + Na(g) \xrightarrow{750^\circ C} NaCl(s) + K(g)}$$

Although the equilibrium constant for this reaction is not particularly favorable, the reaction runs to the right because potassium is more volatile than sodium: the potassium vapor is driven off by the heat and condensed in a cooled collecting vessel.

All the Group 1 elements are soft, lustrous, low-density metals (Fig. 15.11). Lithium, sodium, and potassium are the only metals that are less dense than water. Because the valence shell consists of a single electron, bonding in the metals is weak, leading to low melting and boiling points that decrease down the group (Fig. 15.12). Cesium, which melts at 28°C, is barely a solid at room temperature. Lithium is the hardest alkali metal, but it is softer than lead. Francium is intensely radioactive, and little is known about the properties of this very rare element.

Lithium metal had few uses until after World War II, when thermonuclear weapons were developed (see Section 17.11). This application has had an effect on the molar mass of lithium. Because only lithium-6 could be used in these weapons, the proportion of lithium-7 and, as a result, the molar mass of commercially available lithium has increased. A growing application of lithium is in the rechargeable lithium-ion battery. Because lithium has the most negative standard potential of all the elements, it can produce a high potential when used in a galvanic cell. Furthermore, because lithium has such a low density, lithium-ion batteries are light.

The first ionization energies of the alkali metals are low, and so in their compounds they exist as singly charged cations, such as Na^+. As a result, most of their compounds are ionic. Because their ionization energies are so low, the standard potentials of the alkali metals are all negative. However, $E°$ does not vary as smoothly as the ionization energy, because the lattice energy of the solid and the hydration energy of the ions play a role in determining $E°$; entropy effects also contribute.

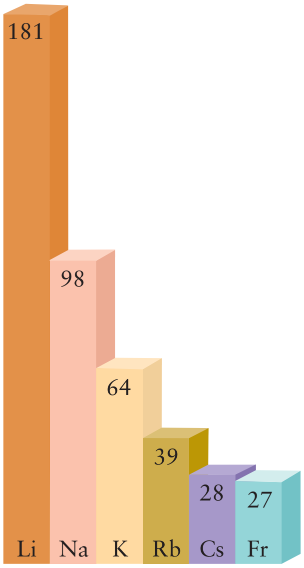


FIGURE 15.12 The melting points of the alkali metals decrease down the group. The numerical values shown here are degrees Celsius.

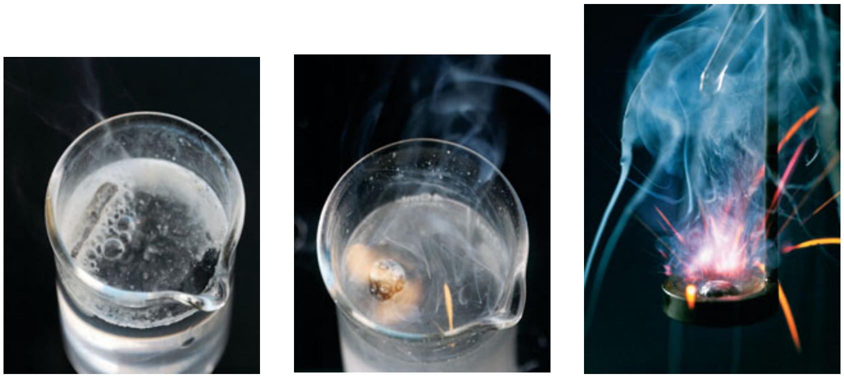

(a) (b) (c)

FIGURE 15.13 The alkali metals react with water, producing gaseous hydrogen and a solution of the alkali metal hydroxide. (a) Lithium reacts slowly. (b) Sodium reacts so vigorously that the heat released melts the unreacted metal and ignites the hydrogen. (c) Potassium reacts even more vigorously.

FIGURE 15.14 The blue swirls in this flask of liquid ammonia formed when small pieces of sodium were added and dissolved.

Because their standard potentials are so strongly negative, all the alkali metals are strong reducing agents that react with water:

$$2\,Na(s) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g)$$

The vigor of this reaction increases uniformly down the group (Fig. 15.13). The reaction of water with sodium and potassium is vigorous enough to ignite the hydrogen; with rubidium and cesium it is dangerously explosive. Rubidium and cesium are denser than water, and so they sink and react beneath the surface; the rapidly evolved hydrogen gas then forms a shock wave that can shatter the vessel. Lithium is the least active of the Group 1 metals in the reaction with water mainly because of the greater strength with which its atoms are bound together, but molten lithium is one of the most active metals known.

The alkali metals also release their valence electrons when they dissolve in liquid ammonia, but the outcome is different. Instead of reducing the ammonia, the electrons occupy cavities formed by groups of NH_3 molecules and give ink-blue *metal–ammonia solutions* (Fig. 15.14). These solutions of solvated electrons (and cations of the metal) are often used to reduce organic compounds. As the metal concentration is increased, the blue gives way to a metallic bronze, and the solutions begin to conduct electricity like liquid metals.

All alkali metals react directly with almost all nonmetals except the noble gases. However, only lithium reacts with nitrogen, which it reduces to the nitride ion (N^{3-}):

$$6\,Li(s) + N_2(g) \longrightarrow 2\,Li_3N(s)$$

The principal product of the reaction of the alkali metals with oxygen varies systematically down the group (Fig. 15.15). Lithium forms mainly the oxide, Li_2O. Sodium

FIGURE 15.15 Although the alkali metals form a mixture of products when they react with oxygen, lithium gives mainly the oxide (left), sodium the very pale yellow peroxide (center), and potassium the yellow superoxide (right).

forms predominantly the very pale yellow sodium peroxide, Na_2O_2, which contains the peroxide ion O_2^{2-}, and potassium forms mainly the superoxide, KO_2, which contains the superoxide ion, O_2^-.

Self-Test 15.4A Write the chemical equation for the reaction between lithium and oxygen.

[***Answer:*** $4\ Li(s) + O_2(g) \rightarrow 2\ Li_2O(s)$]

Self-Test 15.4B Write the chemical equation for the reaction between potassium and oxygen.

The alkali metals are highly reactive metals and so they are usually found as singly charged cations. They react with water with increasing vigor down the group.

15.6 Compounds of Lithium, Sodium, and Potassium

Lithium is typical of an element at the head of its group, in that it differs significantly from its congeners. The differences stem in part from the small size of the Li^+ cation, which gives it a strong polarizing power and hence a tendency to form bonds with significant covalent character. A further consequence of the small size of a Li^+ ion is strong ion–dipole interactions, with the result that many lithium salts form hydrates. Lithium has a diagonal relationship with magnesium and is found in magnesium minerals, where it replaces the magnesium ion.

Lithium compounds are used in ceramics, lubricants, and medicine. Small daily doses of lithium carbonate are an effective treatment for bipolar (manic-depressive) disorder; but scientists still do not fully understand why. Lithium soaps—the lithium salts of long-chain carboxylic acids—are used as thickeners in lubricating greases for high-temperature applications because they have higher melting points than more conventional sodium and potassium soaps.

Two factors that make sodium compounds important are their low cost and their high solubility in water. Sodium chloride is readily mined as rock salt, which is a deposit of sodium chloride left as ancient oceans evaporated; it is also obtained from the evaporation of brine (salt water) from present-day seas and salt lakes (Fig. 15.16). Sodium chloride is used in large quantities in the electrolytic production of chlorine and sodium hydroxide from brine.

Sodium hydroxide, NaOH, is a soft, waxy, white, corrosive solid that is sold commercially as lye. It is an important industrial chemical because it is an inexpensive starting material for the production of other sodium salts. The amount of electricity used to electrolyze brine to produce NaOH in the chloralkali process is second only to the amount used to extract aluminum from its ores. The process produces chlorine and hydrogen gases as well as aqueous sodium hydroxide (Fig. 15.17). The net ionic equation for the reaction is

$$2\ Cl^-(aq) + 2\ H_2O(l) \xrightarrow{\text{electrolysis}} Cl_2(g) + 2\ OH^-(aq) + H_2(g)$$

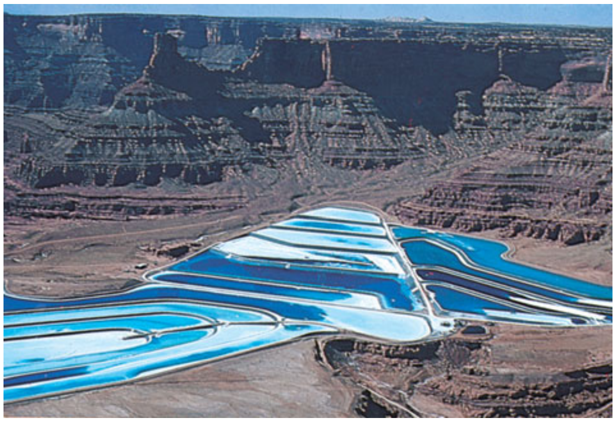

FIGURE 15.16 An evaporation pond. The blue color is due to a dye added to the brine to increase heat absorption and hence speed up evaporation.

Sodium hydrogen carbonate, $NaHCO_3$ (sodium bicarbonate), is commonly called *bicarbonate of soda* or *baking soda*. The rising action of baking soda in batter depends on the reaction of a weak acid, HA, with the hydrogen carbonate ions:

$$HCO_3^-(aq) + HA(aq) \longrightarrow A^-(aq) + H_2O(l) + CO_2(g)$$

The release of gas causes the batter to rise. The weak acids are provided by the recipe, generally in the form of lactic acid from sour milk or buttermilk, citric acid from lemons, or the acetic acid in vinegar. *Baking powder* contains a solid weak acid as well as the hydrogen carbonate, and carbon dioxide is released when water is added.

Sodium carbonate decahydrate, $Na_2CO_3 \cdot 10H_2O$, was once widely used as *washing soda*. It is still sometimes added to water to precipitate Mg^{2+} and Ca^{2+} ions as carbonates, as in

$$Ca^{2+}(aq) + CO_3^{2-}(aq) \longrightarrow CaCO_3(s)$$

and to provide an alkaline environment that helps to remove grease from fabrics. Anhydrous sodium carbonate, or *soda ash*, is used in large amounts in the glass industry as a source of sodium oxide, into which it decomposes when heated (Section 6.10).

Thinking point. Why is calcium carbonate much less soluble than sodium carbonate?

Potassium compounds have many similarities to sodium compounds. The principal mineral sources of potassium are *carnallite*, $KCl \cdot MgCl_2 \cdot 6H_2O$, and *sylvite*, KCl, which is incorporated directly into some fertilizers as a source of essential potassium. Potassium compounds are generally more expensive than the corresponding sodium compounds, but in some applications their advantages outweigh their expense. For example, potassium nitrate, KNO_3, releases oxygen when heated, in the reaction

$$2\,KNO_3(s) \xrightarrow{\Delta} 2\,KNO_2(s) + O_2(g)$$

and is used to facilitate the ignition of matches. It is less hygroscopic (water absorbing) than the corresponding sodium compounds, because the potassium cation is larger and is less strongly hydrated by H_2O molecules.

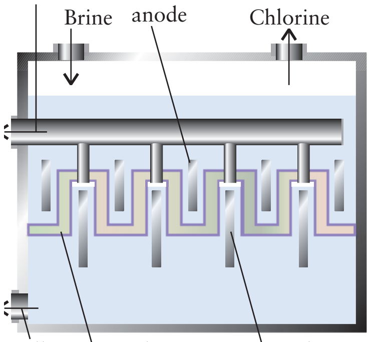

FIGURE 15.17 A diaphragm cell for the electrolytic production of sodium hydroxide from brine (aqueous sodium chloride solution), represented by the blue color. The diaphragm prevents the chlorine produced at the titanium anodes from mixing with the hydrogen and the sodium hydroxide formed at the steel cathodes. The liquid (cell liquor) is drawn off and the water is partly evaporated. The unconverted sodium chloride crystallizes, leaving the sodium hydroxide dissolved in the cell liquor.

Self-Test 15.5A Use Table 13.1 to determine the minimum potential difference that must be applied under standard conditions to carry out the chloralkali process.

[*Answer:* 2.19 V]

Self-Test 15.5B Like KO_2, cesium superoxide, CsO_2, can be used to remove exhaled CO_2 and generate oxygen from water. Explain why KO_2 is preferred for this purpose on spacecraft.

Lithium resembles magnesium, and its compounds show covalent character. Sodium compounds are soluble in water, plentiful, and inexpensive. Potassium compounds are generally less hygroscopic than sodium compounds.

GROUP 2: THE ALKALINE EARTH METALS

Calcium, strontium, and barium are called the *alkaline earth metals*, because their "earths"—the old name for oxides—are basic (alkaline). The name alkaline earth metal is often extended to all the members of Group 2 (Table 15.4).

TABLE 15.4 Group 2 Elements

Valence configuration: ns^2
Normal form*: soft, silver-gray metals

Z	Name	Symbol	Molar mass ($g \cdot mol^{-1}$)	Melting point (°C)	Boiling point (°C)	Density ($g \cdot cm^{-3}$)
4	beryllium	Be	9.01	1285	2470	1.85
12	magnesium	Mg	24.31	650	1100	1.74
20	calcium	Ca	40.08	840	1490	1.53
38	strontium	Sr	87.62	770	1380	2.58
56	barium	Ba	137.33	710	1640	3.59
88	radium	Ra	(226)	700	1500	5.00

**Normal form* means the state and appearance of the element at 25°C and 1 atm.

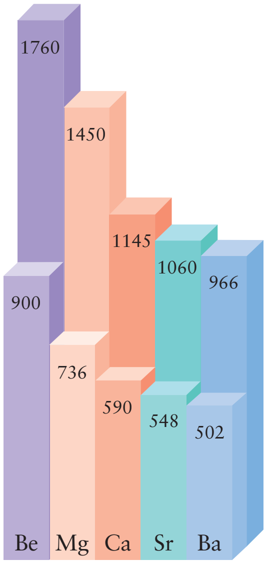

FIGURE 15.18 The first (front row) and second (back row) ionization energies (in kilojoules per mole) of the Group 2 elements. Although the second ionization energies are larger than the first, they are not enormous, and both valence electrons are lost from each atom in all the compounds of these elements.

Magnesium is uniquely important for humanity, because it is, in effect, the doorway to life: it is present in every chlorophyll molecule and hence enables photosynthesis to take place. Calcium is the element of rigidity and construction: it is the cation in the bones of our skeletons, the shells of shellfish, and the concrete, mortar, and limestone of buildings (see Sections 6.6 and 6.8).

15.7 The Group 2 Elements

The valence electron configuration of the atoms of the Group 2 elements is ns^2. The second ionization energy is low enough to be recovered from the lattice enthalpy (Fig. 15.18). Hence, the Group 2 elements occur with an oxidation number of +2, as the cation M^{2+}, in all their compounds. Apart from a tendency toward nonmetallic character in beryllium, the elements have all the chemical characteristics of metals, such as forming basic oxides and hydroxides.

All the Group 2 elements are too reactive to occur in the uncombined state in nature (Fig. 15.19). Instead, they are generally found in compounds as doubly charged cations. The element beryllium occurs mainly as *beryl*, $3BeO{\cdot}Al_2O_3{\cdot}6SiO_2$, sometimes in crystals so big that they weigh several tons. The gemstone *emerald* is a form of beryl; its green color is caused by Cr^{3+} ions present as impurities (Fig. 15.20). Magnesium occurs in seawater and as the mineral *dolomite*, $CaCO_3{\cdot}MgCO_3$. Calcium also occurs as $CaCO_3$ in compressed deposits of the shells of ancient marine organisms and exoskeletons of tiny one-celled organisms; these deposits include *limestone*, *calcite*, and *chalk* (a softer variety of calcium carbonate).

Beryllium is obtained by electrolytic reduction of molten beryllium chloride. The element's low density makes it useful for the construction of missiles and satellites. Beryllium is also used as windows for x-ray tubes: because Be atoms have so few electrons, thin sheets of the metal are transparent to x-rays and allow the rays to escape. Beryllium is added in small amounts to copper: the small Be atoms pin the Cu atoms together in an interstitial alloy that is more rigid than pure copper but still conducts electricity well. These hard, electrically conducting alloys are formed into nonsparking tools for use in oil refineries and grain elevators, where there is a risk of explosion. Beryllium–copper alloys are also used in the electronics industry to form tiny nonmagnetic parts and contacts that resist deformation and corrosion.

Metallic magnesium is produced by either chemical or electrolytic reduction of its compounds. In chemical reduction, first magnesium oxide is obtained from the thermal decomposition of dolomite. Then ferrosilicon, an alloy of iron and silicon, is used to reduce the MgO at about 1200°C. At this temperature, the magnesium produced is immediately vaporized and carried away. The electrolytic method uses seawater as its principal raw material: magnesium hydroxide is precipitated by adding

(a) (b) (c) (d) (e)

FIGURE 15.19 The elements of Group 2: (a) beryllium; (b) magnesium; (c) calcium; (d) strontium; and (e) barium. The four central elements of the group (magnesium through barium) were discovered by Humphry Davy in a single year (1808). The two outer elements were discovered later: beryllium in 1828 (by Friedrich Wöhler) and radium (which is not shown here) in 1898 (by Pierre and Marie Curie).

slaked lime ($Ca(OH)_2$, see Section 15.8), the precipitate is filtered off and treated with hydrochloric acid to produce magnesium chloride, and the dried molten salt is electrolyzed.

Magnesium is a silver-white metal that is protected from extensive oxidation in air by a film of white oxide, which gives the metal a dull gray coat. Its density is only two-thirds that of aluminum, and the pure metal is very soft. However, its alloys have great strength, and they are used in applications requiring lightness and toughness—in airplanes, for instance. The use of magnesium alloys in automobiles increased by a factor of 5 between 1989 and 1995 as manufacturers sought to reduce the weight of vehicles. However, don't expect to be driving a magnesium car soon: magnesium is more expensive than steel and more difficult to work. It melts at a low temperature and is deformed by the heat produced when it is machined. Water cannot be used to cool the tools because magnesium reacts with hot water to produce hydrogen.

Magnesium burns vigorously in air with a brilliant white flame, partly because it reacts with the nitrogen and carbon dioxide in air as well as with oxygen. Because the reaction is accelerated when burning magnesium is sprayed with water or exposed to carbon dioxide, neither water nor CO_2 fire extinguishers should ever be used on a magnesium fire. They will only make the fire worse!

FIGURE 15.20 An emerald is a crystal of beryl with some Cr^{3+} ions, which are responsible for the green color.

The true alkaline earth metals—calcium, strontium, and barium—are obtained either by electrolysis or by reduction with aluminum in a version of the thermite process (see Fig. 7.8):

$$3\,BaO(s) + 2\,Al(s) \xrightarrow{\Delta} Al_2O_3(s) + 3\,Ba(s)$$

As in Group 1, reactions of the Group 2 metals with oxygen and water increase in vigor going down the group. Beryllium, magnesium, calcium, and strontium are partly passivated in air by a protective surface layer of oxide. Barium, however, does not form a protective oxide and may ignite in moist air.

All the Group 2 elements with the exception of beryllium react with water; for example,

$$Ca(s) + 2\,H_2O(l) \longrightarrow Ca^{2+}(aq) + 2\,OH^-(aq) + H_2(g)$$

Beryllium does not react with water, even when red hot: its protective oxide film survives even at high temperatures. Magnesium reacts with hot water (see Fig. 14.22), and calcium reacts with cold water (Fig. 15.21). The metals reduce hydrogen ions to hydrogen gas, but neither beryllium nor magnesium dissolves in nitric acid, because both become passivated by a film of oxide.

The alkaline earth metals can be detected in burning compounds by the colors that they give to flames. Calcium burns orange-red, strontium crimson, and barium yellow-green. Fireworks are often made from their salts (typically nitrates and chlorates, because the anions then provide an additional supply of oxygen) together with magnesium powder.

FIGURE 15.21 Calcium reacts gently with cold water to produce hydrogen and calcium hydroxide, $Ca(OH)_2$.

Self-Test 15.6A Write the chemical equation for the reaction that would occur if you tried to put out a magnesium fire with water.

[*Answer:* $Mg(s) + 2\,H_2O(l) \longrightarrow Mg^{2+}(aq) + 2\,OH^-(aq) + H_2(g)$]

Self-Test 15.6B Write the chemical equation for the reaction of barium with oxygen.

Beryllium shows a hint of nonmetallic character, but the other Group 2 elements are all reactive metals. The vigor of reaction with water and oxygen increases down the group.

15.8 Compounds of Beryllium, Magnesium, and Calcium

Beryllium, at the head of Group 2, resembles its diagonal neighbor aluminum in its chemical properties. It is the least metallic element of the group, and many of its compounds have properties commonly attributed to covalent bonding. Beryllium is amphoteric and reacts with both acids and alkalis. Like aluminum, beryllium reacts with

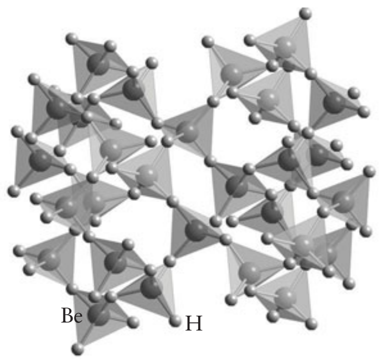

FIGURE 15.22 The network structure of beryllium hydride is based on tetrahedral BeX_4 units.

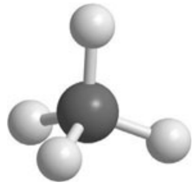
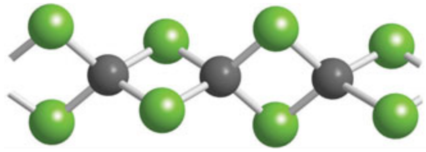


2 BeX_4 unit



3 Beryllium chloride, $BeCl_2$

water in the presence of sodium hydroxide; the products are the *beryllate ion*, $Be(OH)_4{}^{2-}$, and hydrogen:

$$Be(s) + 2\ OH^-(aq) + 2\ H_2O(l) \longrightarrow Be(OH)_4{}^{2-}(aq) + H_2(g)$$

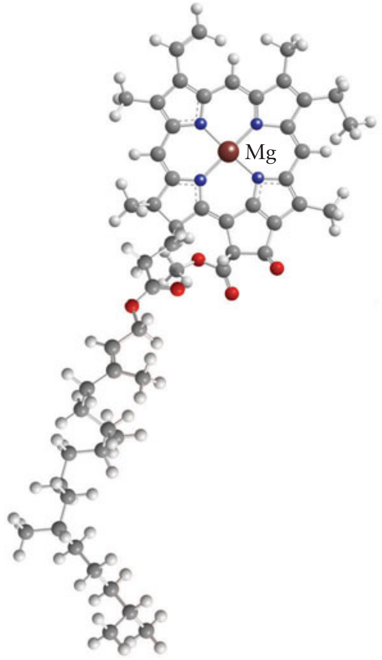
Beryllium compounds are very toxic and must be handled with great caution. Their properties are dominated by the highly polarizing character of the Be^{2+} ion and its small size. The strong polarizing power results in moderately covalent compounds, and its small size limits to four the number of groups that can attach to the ion. These two features together are responsible for the prominence of the tetrahedral BeX_4 unit (**2**), like that in the beryllate ion. A tetrahedral unit is also found in the solid chloride (**3**) and hydride. Beryllium hydride was once thought to consist of chains of BeH_2 groups, but it is now known to have a network structure (Fig. 15.22). The chloride is made by the action of chlorine on the oxide in the presence of carbon:

$$BeO(s) + C(s) + Cl_2(g) \xrightarrow{600\text{–}800\,°C} BeCl_2(g) + CO(g)$$

The Be atoms in $BeCl_2$ act as Lewis acids and accept electron pairs from the Cl atoms of the neighboring linear $BeCl_2$ groups, forming a chain of tetrahedral $BeCl_4$ units in the solid.

Magnesium has more pronounced metallic properties than beryllium; its compounds are primarily ionic, with some covalent character. Magnesium oxide, MgO, is formed when magnesium burns in air, but the product is contaminated by magnesium nitride. To prepare the pure oxide, the hydroxide or the carbonate is heated. Magnesium oxide dissolves only very slightly in water. One of its most striking properties is that it is *refractory* (able to withstand high temperatures); it melts at 2800°C. This high stability can be traced to the small ionic radii of the Mg^{2+} and O^{2-} ions and hence to their very strong electrostatic interaction with each other. The oxide has two other useful characteristics: it conducts heat very well, and it conducts electricity poorly. All three properties make it useful as an insulator in electric heaters.

Magnesium hydroxide, $Mg(OH)_2$, is a base. It is not very soluble in water but forms instead a white colloidal suspension, a mist of small particles dispersed through a liquid (see Section 9.21), which is known as *milk of magnesia* and used as a stomach antacid. Because this base is relatively insoluble, it is not absorbed from the stomach but remains to act on whatever acids are present. Hydroxides have an advantage over hydrogen carbonates (which also are used as antacids) in that their neutralization does not lead to the formation of carbon dioxide and its consequence, belching. Milk of magnesia must be used sparingly as an antacid, because the salt produced by the neutralization of milk of magnesia in the stomach is magnesium chloride, which can act as a purgative. Magnesium sulfate, as *Epsom salts*, $MgSO_4{\cdot}7H_2O$, is another common purgative. The magnesium ions inhibit the absorption of water from the intestine. The resulting increased flow of water through the intestine triggers the mechanism that results in defecation.



4 Chlorophyll

Arguably the most important compound of magnesium is chlorophyll. This green organic compound consists of large molecules that capture light from the Sun and channel its energy into photosynthesis. One function of the Mg^{2+} ion, which lies just above the plane of the ring (**4**), appears to be to keep the ring rigid. This rigidity helps to ensure that the energy captured from the incoming photon is not lost as heat before it has been used to bring about a chemical reaction. Magnesium also plays an important role in energy generation in living cells. For example, it is involved in the contraction of muscles.

The most common compound of calcium is calcium carbonate, $CaCO_3$, which occurs naturally in a variety of forms such as chalk and limestone. These minerals, which are described in Section 6.6, are the compressed remains of shells and skeletons of marine life.

Calcium carbonate decomposes to calcium oxide, CaO, or *quicklime*, when heated:

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$$

Calcium oxide is called quicklime because it reacts so exothermically and rapidly with water:

$$CaO(s) + H_2O(l) \longrightarrow Ca^{2+}(aq) + 2\ OH^-(aq)$$

The product, calcium hydroxide, is commonly known as *slaked lime* because, as calcium hydroxide, the thirst of lime for water has been quenched (slaked). Slaked lime is the form in which lime is normally sold because quicklime can set fire to moist wood and paper. In fact, the wooden boats that were once used to transport quicklime sometimes caught fire in the heat of reaction when water seeped into their holds. An aqueous solution of calcium hydroxide, which is slightly soluble in water, is called *lime water*. It is used as a test for carbon dioxide, with which it reacts to form a cloudy suspension of the much less soluble calcium carbonate:

$$Ca(OH)_2(aq) + CO_2(g) \longrightarrow CaCO_3(s) + H_2O(l)$$

Quicklime is produced in enormous quantities throughout the world. About 40% of this output is used in metallurgy. In ironmaking (Section 16.3), it is used as a Lewis base; its O^{2-} ion reacts with silica, SiO_2, impurities in the ore to form a liquid *slag*:

$$CaO(s) + SiO_2(s) \xrightarrow{\Delta} CaSiO_3(l)$$

About 50 kg of lime is needed to produce 1 tonne (10^3 kg) of iron.

Slaked lime is used as an inexpensive base in industry, as well as to adjust the pH of soils in agriculture. Perhaps surprisingly, it is also used to *remove* Ca^{2+} ions from hard water containing $Ca(HCO_3)_2$. Its role here is to convert HCO_3^- into CO_3^{2-} by providing OH^- ions:

$$HCO_3^-(aq) + OH^-(aq) \longrightarrow CO_3^{2-}(aq) + H_2O(l)$$

As the concentration of CO_3^{2-} ions rises, Ca^{2+} ions precipitate in the reaction

$$Ca^{2+}(aq) + CO_3^{2-}(aq) \longrightarrow CaCO_3(s)$$

This reaction removes the Ca^{2+} ions that were present initially and those that were added as lime; overall, the Ca^{2+} ion concentration is reduced.

Thinking point: Why is calcium hydrogen carbonate (bicarbonate) more soluble than calcium carbonate?

Teeth are generally denser than bone and are protected by a hard enamel coating. Tooth enamel is a *hydroxyapatite*, $Ca_5(PO_4)_3OH$. Tooth decay begins when acids attack the enamel:

$$Ca_5(PO_4)_3OH(s) + 4\ H_3O^+(aq) \longrightarrow 5\ Ca^{2+}(aq) + 3\ HPO_4^{2-}(aq) + 5\ H_2O(l)$$

The principal agents of tooth decay are the carboxylic acids produced when bacteria act on the remains of food. A more resistant coating forms when the OH^- ions in the apatite are replaced by F^- ions. The resulting mineral is called *fluorapatite*:

$$Ca_5(PO_4)_3OH(s) + F^-(aq) \longrightarrow Ca_5(PO_4)_3F(s) + OH^-(aq)$$

The addition of fluoride ions to domestic water supplies (in the form of NaF) is now widespread and has resulted in a dramatic decrease in dental cavities. Fluoridated toothpastes, containing either tin(II) fluoride or sodium monofluorophosphate (MFP, Na_2FPO_3), are also recommended to strengthen tooth enamel.

Self-Test 15.7A Explain why beryllium compounds have covalent characteristics.

[***Answer:*** The small size and high charge on the beryllium ion make it highly polarizing.]

Self-Test 15.7B Is the reaction between CaO and SiO_2 a redox reaction or a Lewis acid–base reaction? If redox, identify the oxidizing and reducing agents. If Lewis acid–base, identify the acid and the base.

Beryllium compounds have a pronounced covalent character, and the structural unit is commonly tetrahedral. The small size of the magnesium cation results in a thermally stable oxide with low solubility in water. Calcium compounds are common in structural materials because the small, highly charged Ca^{2+} ion results in rigid structures.

GROUP 13/III: THE BORON FAMILY

Now we move into the p-block of the periodic table and encounter the complex but fascinating world of the nonmetals. Here, close to the center of the periodic table, we meet strange properties, because the elements are neither so electropositive that they easily lose electrons nor so electronegative that they easily gain them.

Group 13/III is the first group of the p block. Its members have an ns^2np^1 electron configuration (Table 15.5), and so we expect a maximum oxidation number of +3. The oxidation numbers of B and Al are +3 in almost all their compounds. However, the heavier elements in the group are more likely to keep their s-electrons (the inert-pair effect, Section 1.19); so the oxidation number +1 becomes increasingly important down the group, and thallium(I) compounds are as common as thallium(III) compounds. We shall concentrate on the two most important members of the group, boron and aluminum.

15.9 The Group 13/III Elements

Boron forms perhaps the most extraordinary structures of all the elements. It has a high ionization energy and is a metalloid that forms covalent bonds, like its diagonal neighbor silicon. However, because it has only three electrons in its valence shell and has a small atomic radius, it tends to form compounds that have incomplete octets (Section 2.11) or are electron deficient (Section 3.8). These unusual bonding characteristics lead to the remarkable properties that have made boron an essential element of modern technology and, in particular, nanotechnology.

Boron is mined as *borax* and *kernite*, $Na_2B_4O_7{\cdot}xH_2O$, with $x = 10$ and 4, respectively. Large deposits from ancient hot springs are found in volcanic regions, such as the Mojave Desert region of California. In the extraction process, the ore is converted into boron oxide with acid and then reduced with magnesium to an impure brown, amorphous form of boron:

$$B_2O_3(s) + 3\,Mg(s) \xrightarrow{\Delta} 2\,B(s) + 3\,MgO(s)$$

A product of higher purity is obtained by reducing a volatile boron compound, such as BCl_3 or BBr_3, with hydrogen on a heated filament (tantalum is used for the filament because it has a very high melting point):

$$2\,BBr_3(g) + 3\,H_2(g) \xrightarrow{\Delta} 2\,B(s) + 6\,HBr(g)$$

TABLE 15.5 Group 13/III Elements

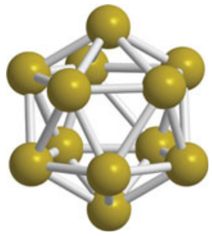
Valence configuration: ns^2np^1

Z	Name	Symbol	Molar mass ($g{\cdot}mol^{-1}$)	Melting point (°C)	Boiling point (°C)	Density ($g{\cdot}cm^{-3}$)	Normal form*
5	boron	B	10.81	2300	3931	2.47	powdery brown metalloid
13	aluminum	Al	26.98	660	2467	2.70	silver-white metal
31	gallium	Ga	69.72	30	2403	5.91	silver metal
49	indium	In	114.82	156	2080	7.29	silver-white metal
81	thallium	Tl	204.38	304	1457	11.87	soft metal

**Normal form* means the state and appearance of the element at 25°C and 1 atm.

Because of the expense, boron production remains quite low despite the element's desirable properties of hardness and low density.

Elemental boron exists in a variety of allotropic forms in which each atom strives to find ways to share eight electrons despite being so small and having only three electrons to contribute. It is most commonly found as either a gray-black nonmetallic, high-melting-point solid or a dark brown powder with an icosahedral (20-faced) structure based on clusters of 12 atoms (5). Because of the three-dimensional network formed by these bonds, boron is very hard and is chemically unreactive. When boron fibers are incorporated into plastics, the result is a very tough composite material that is stiffer than steel yet lighter than aluminum; this material is used in aircraft, missiles, and body armor (see Section 19.12). The element is attacked by only the strongest oxidizing agents.



5 B_{12}

Here, perhaps, is an opportunity for another young chemist like Hall to transform the production of boron as Hall did for aluminum (described later in this section).

Aluminum is the most abundant metallic element in the Earth's crust and, after oxygen and silicon, the third most abundant element (see Fig. 15.1). However, the aluminum content in most minerals is low, and the commercial source of aluminum, *bauxite*, is a hydrated, impure oxide, $Al_2O_3 \cdot xH_2O$, where x can range from 1 to 3. Bauxite ore, which is red from the iron oxides that it contains (Fig. 15.23), is processed to obtain alumina, Al_2O_3, in the *Bayer process*. In this process, the ore is first treated with aqueous sodium hydroxide, which dissolves the amphoteric alumina as the aluminate ion, $Al(OH)_4^-$. Carbon dioxide is then bubbled through the solution to remove OH^- ions as HCO_3^- and to convert some of the aluminate ions into aluminum hydroxide, which precipitates. The aluminum hydroxide is removed and dehydrated to the oxide by heating to 1200°C.

FIGURE 15.23 The iron oxides in bauxite ore give it a red tint.

Obtaining aluminum metal from the oxide was a challenge to early scientists and engineers. When it was first isolated, aluminum was a rare and expensive metal. During the nineteenth century, it so symbolized modern technology that the Washington Monument was given an expensive aluminum tip. That rarity and expense were transformed by electrochemistry. Aluminum metal is now obtained on a huge scale by the *Hall process*. In 1886, Charles Hall discovered that, by mixing the mineral cryolite, Na_3AlF_6, with alumina, he got a mixture that melts at a much more economical temperature, 950°C, instead of the 2050°C of pure alumina. The melt is electrolyzed in a cell that uses graphite (or carbonized petroleum) anodes and a carbonized steel-lined vat that serves as the cathode (Fig. 15.24). The electrolysis half-reactions are

Napoleon reserved his aluminum plates for his special guests: the rest had to make do with gold.

Cathode reaction: $Al^{3+}(melt) + 3\,e^- \longrightarrow Al(l)$

Anode reaction: $2\,O^{2-}(melt) + C(s, gr) \longrightarrow CO_2(g) + 4\,e^-$

Overall reaction: $4\,Al^{3+}(melt) + 6\,O^{2-}(melt) + 3\,C(s, gr) \longrightarrow 4\,Al(l) + 3\,CO_2(g)$

Note that the carbon electrode is consumed in the reaction. From the reaction stoichiometry, we can calculate that a current of 1 A must flow for 80 h to produce 1 mol Al (27 g of aluminum, about enough for two soft-drink cans). The very high energy consumption can be greatly reduced by recycling, which requires less than 5% of the electricity needed to extract aluminum from bauxite. Although a 12-ounce beverage can contains less than 14 g of aluminum, the energy that we are throwing away when we discard an aluminum can is equivalent to burning the amount of gasoline that would fill half the can. Note also that the production of 1 tonne of aluminum from alumina is accompanied by the release of more than 1 tonne of carbon dioxide into the atmosphere.

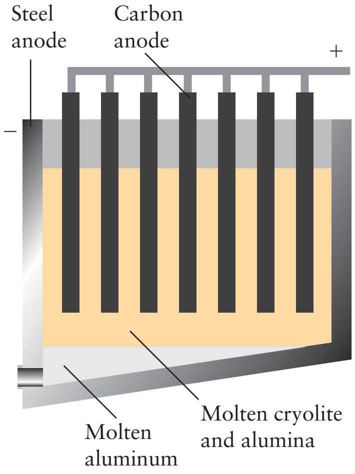


FIGURE 15.24 In the Hall process, aluminum oxide is dissolved in molten cryolite and the mixture is electrolyzed in a cell with carbon anodes and a steel cathode. The molten aluminum flows out of the bottom of the cell.

Aluminum has a low density; it is a strong metal and an excellent electrical conductor. Although it is strongly reducing and therefore easily oxidized, aluminum is resistant to corrosion because its surface is passivated in air by a stable oxide film. The thickness of the oxide layer can be increased by making aluminum the anode of an electrolytic cell; the result is called *anodized aluminum*. Dyes may be added to the dilute sulfuric acid electrolyte used in the anodizing process to produce surface layers with different colors.

Aluminum's low density, wide availability, and corrosion resistance make it ideal for construction and for the aerospace industry. Aluminum is a soft metal, and so it is usually alloyed with copper and silicon for greater strength. Its lightness and good electrical conductivity have also led to its use for overhead power lines, and its negative

electrode potential has led to its use in fuel cells. Perhaps one day your automobile will not only be made of aluminum but fueled by it, too.

Boron, at the head of Group 13/III, is best regarded as a nonmetal in most of its chemical properties. It has acidic oxides and forms an interesting and extensive range of binary molecular hydrides. Metallic character increases down the group, and even boron's immediate neighbor aluminum is a metal. Nonetheless, aluminum is sufficiently far to the right in the periodic table to show a hint of nonmetallic character. Aluminum is amphoteric, reacting both with nonoxidizing acids (such as hydrochloric acid) to form aluminum ions:

An oxidizing acid is an oxoacid in which the anion is an oxidizing agent; examples are HNO_3 and $HClO_3$.

$$2\,Al(s) + 6\,H^+(aq) \longrightarrow 2\,Al^{3+}(aq) + 3\,H_2(g)$$

and with hot aqueous alkali to form aluminate ions:

$$2\,Al(s) + 2\,OH^-(aq) + 6\,H_2O(l) \longrightarrow 2\,Al(OH)_4{}^-(aq) + 3\,H_2(g)$$

Gallium, which is produced as a by-product in the Bayer process, has important uses in the electronics industry. It is a common doping agent for semiconductors and some of its compounds, such as GaAs, are used in light-emitting diodes to convert electricity into light. Thallium, at the bottom of Group 13/III, is a dangerously poisonous heavy metal that has been used as a rat poison. However, concern about its accumulation in the environment has spurred research into alternative pesticides.

Boron is a hard metalloid with pronounced nonmetallic properties. Aluminum is a light, strong, amphoteric, reactive metallic element with a surface that becomes passivated when exposed to air.

15.10 Group 13/III Oxides and Halides

Boron, a metalloid with largely nonmetallic properties, has acidic oxides. Aluminum, its metallic neighbor, has amphoteric oxides (like its diagonal neighbor in Group 2, beryllium). The oxides of both elements are important in their own right, as sources of the elements, and as the starting point for the manufacture of other compounds.

Boric acid, $B(OH)_3$, is a white solid that melts at 171°C. It is toxic to bacteria and many insects as well as humans and has long been used as a mild antiseptic and pesticide. Because the boron atom in $B(OH)_3$ has an incomplete octet, it can act as a Lewis acid and form a bond by accepting a lone pair of electrons from an H_2O molecule acting as a Lewis base:

$$(OH)_3B + {:}OH_2 \longrightarrow (OH)_3B{-}OH_2$$

The compound so formed is a weak *mono*protic acid:

$$B(OH)_3OH_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + B(OH)_4{}^-(aq) \qquad pK_a = 9.14$$

The major use of boric acid is as the starting material for its anhydride, boron oxide, B_2O_3. Because it melts (at 450°C) to a liquid that dissolves many metal oxides, boron oxide (often as the acid) is used as a *flux*, a substance that cleans metals as they are soldered or welded. Boron oxide is also used to make fiberglass and borosilicate glass, a glass with a very low thermal expansion, such as Pyrex (see Section 6.10).

Aluminum oxide, Al_2O_3, is known almost universally as *alumina*. It exists with a variety of crystal structures, many of which form important ceramic materials (see Section 6.11). Some impure forms of alumina are beautiful, rare, and highly prized (Fig. 15.25). A less dense and more reactive form of the oxide is γ-alumina. This form absorbs water and is used as the stationary phase in chromatography.

γ-Alumina is produced by heating aluminum hydroxide. It is moderately reactive and is amphoteric, dissolving readily in bases to produce the aluminate ion and in acids to produce the hydrated Al^{3+} ion:

$$Al_2O_3(s) + 2\,OH^-(aq) + 3\,H_2O(l) \longrightarrow 2\,Al(OH)_4{}^-(aq)$$
$$Al_2O_3(s) + 6\,H_3O^+(aq) + 3\,H_2O(l) \longrightarrow 2\,Al(H_2O)_6{}^{3+}(aq)$$

(a) (b) (c)

FIGURE 15.25 Some of the impure forms of α-alumina are prized as gems. (a) Ruby is alumina with Cr^{3+} in place of some Al^{3+} ions. (b) Sapphire is alumina with Fe^{3+} and Ti^{4+} impurities. (c) Topaz is alumina with Fe^{3+} impurities.

As described in Section 11.13, the strong polarizing effect of the small, highly charged Al^{3+} ion (a Lewis acid) on the water molecules around it (Lewis bases) gives the $Al(H_2O)_6{}^{3+}$ ion acidic properties:

$$Al(H_2O)_6{}^{3+}(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + Al(OH)(H_2O)_5{}^{2+}(aq)$$

One of the most important aluminum salts prepared by the action of an acid on alumina is aluminum sulfate, $Al_2(SO_4)_3$:

$$Al_2O_3(s) + 3\ H_2SO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 3\ H_2O(l)$$

Aluminum sulfate is called *papermaker's alum* and is used in the paper industry to coagulate cellulose fibers into a hard, nonabsorbent surface. True alums (from which aluminum takes its name) are mixed sulfates of formula $M^+M'^{3+}(SO_4)_2 \cdot 12H_2O$. They include potassium alum, $KAl(SO_4)_2 \cdot 12H_2O$ (which is used in water and sewage treatment), and ammonium alum, $NH_4Al(SO_4)_2 \cdot 12H_2O$ (which is used for pickling cucumbers and as the Brønsted acid in baking powders).

Sodium aluminate, $NaAl(OH)_4$, is used along with aluminum sulfate in water purification. When mixed with aluminate ions, the acidic hydrated Al^{3+} cation from the aluminum sulfate produces aluminum hydroxide:

$$Al^{3+}(aq) + 3\ Al(OH)_4{}^-(aq) \longrightarrow 4\ Al(OH)_3(s)$$

The aluminum hydroxide is formed as a fluffy, gelatinous network that entraps impurities as it settles, and this precipitate can be removed by filtration (Fig. 15.26).

FIGURE 15.26 Aluminum hydroxide, $Al(OH)_3$, forms as a white, fluffy precipitate. The fluffy form of the solid captures impurities and is used in the purification of water.

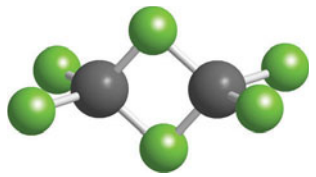
The boron halides are useful industrial catalysts that are made either by direct reaction of the elements at a high temperature or from boron oxide. The most important is boron trifluoride, BF_3, which is produced by the reaction between boron oxide, calcium fluoride, and sulfuric acid:

$$B_2O_3(s) + 3\ CaF_2(s) + 3\ H_2SO_4(l) \xrightarrow{\Delta} 2\ BF_3(g) + 3\ CaSO_4(s) + 3\ H_2O(l)$$

Boron trichloride, BCl_3, which is also widely used as a catalyst, is produced commercially by the action of chlorine gas on the oxide in the presence of carbon:

$$B_2O_3(s) + 3\ C(s) + 3\ Cl_2(g) \xrightarrow{500^\circ C} 2\ BCl_3(g) + 3\ CO(g)$$

The B atom has an incomplete octet in all its trihalides. The compounds consist of trigonal planar molecules with an empty 2p-orbital perpendicular to the molecular plane. The empty orbital allows the molecules to act as Lewis acids, which accounts for the catalytic action of BF_3 and BCl_3.



6 Aluminum chloride dimer, Al_2Cl_6

Aluminum chloride, $AlCl_3$, another major industrial catalyst, is made by the action of chlorine on aluminum or on alumina in the presence of carbon:

$$2\,Al(s) + 3\,Cl_2(g) \longrightarrow 2\,AlCl_3(s)$$

$$Al_2O_3(s) + 3\,C(s) + 3\,Cl_2(g) \longrightarrow 2\,AlCl_3(s) + 3\,CO(g)$$

Aluminum chloride is an ionic solid in which each Al^{3+} ion is coordinated to six Cl^- ions. However, it sublimes at 192°C to a vapor of Al_2Cl_6 molecules (**6**). In this molecule, the Al atom of one $AlCl_3$ planar fragment acts as a Lewis acid and accepts an electron pair from a Cl atom of the other $AlCl_3$ fragment, which is acting as a Lewis base.

Self-Test 15.8A Explain how Al^{3+} forms acidic solutions.

[***Answer:*** In water Al^{3+} forms $Al(H_2O)_6{}^{3+}$; the highly charged Al^{3+} ion polarizes the water molecules, enabling one of them to donate a proton.]

Self-Test 15.8B The compound $B(OH)_3$ does not itself lose any protons in water. Why, then, is it called boric acid?

Boron oxide is an acid anhydride. Aluminum shows some nonmetallic character in that its oxide is amphoteric. Boron and aluminum halides have incomplete octets and act as Lewis acids.

15.11 Boranes and Borohydrides

Boron forms a remarkable series of binary compounds with hydrogen—the *boranes*. These compounds include diborane, B_2H_6, and more complex compounds such as decaborane, $B_{10}H_{14}$. Anionic versions of these compounds, the *borohydrides*, are known; the most important is $BH_4{}^-$ as sodium borohydride, $NaBH_4$.

Sodium borohydride is a white crystalline solid produced from the reaction between sodium hydride and boron trichloride dissolved in a nonaqueous solvent:

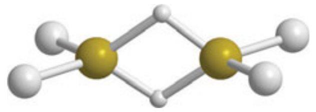
$$4\,NaH + BCl_3 \longrightarrow NaBH_4 + 3\,NaCl$$

Sodium borohydride is a very useful reducing agent. At pH = 14 (strongly alkaline conditions), the potential of the half-reaction

$$H_2BO_3{}^-(aq) + 5\,H_2O(l) + 8e^- \longrightarrow BH_4{}^-(aq) + 8\,OH^-(aq)$$

is −1.24 V. Because this potential is well below that of the Ni^{2+}/Ni couple (−0.23 V), borohydride ions can reduce Ni^{2+} ions to metallic nickel. This reduction is the basis of the "chemical plating" of nickel. The advantage of this chemical plating over electroplating is that the item being plated does not have to be an electrical conductor.

The boranes are an extensive series of binary compounds of boron and hydrogen, somewhat analogous to the hydrocarbons. The starting point for borane production is the reaction (in an organic solvent) of sodium borohydride with boron trifluoride:



7 Diborane, B_2H_6

$$4\,BF_3 + 3\,BH_4{}^- \longrightarrow 3\,BF_4{}^- + 2\,B_2H_6$$

The product B_2H_6 is diborane (**7**), a colorless gas that bursts into flame in air. On contact with water, it immediately reduces the hydrogen in the water:

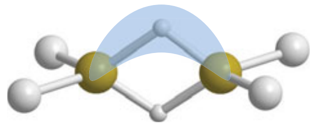
$$B_2H_6(g) + 6\,H_2O(l) \longrightarrow 2\,B(OH)_3(aq) + 6\,H_2(g)$$

When diborane is heated to a high temperature, it decomposes into hydrogen and pure boron:

$$B_2H_6(g) \xrightarrow{\Delta} 2\,B(s) + 3\,H_2(g)$$

This sequence of reactions is a useful route to the pure element, but more complex boranes form when the heating is less severe. When diborane is heated to 100°C, for instance, it forms decaborane, $B_{10}H_{14}$, a solid that melts at 100°C. Decaborane is stable in air, is oxidized by water only slowly, and is an example of the general rule that heavier boranes are less flammable than boranes of low molar mass.

The boranes are electron-deficient compounds (Section 3.8): we cannot write valid Lewis structures for them, because too few electrons are available. For instance, there are 8 atoms in diborane, so we need at least 7 bonds; however, there are only 12 valence electrons, and so we can form at most 6 electron-pair bonds. Molecular orbital theory readily overcomes this difficulty: the six electron pairs are regarded as delocalized over the entire molecule and their bonding power is shared by several atoms. In diborane, for instance, a single electron pair is delocalized over a B—H—B unit. It binds all three atoms together with bond order of $\frac{1}{2}$ for each of the B—H bridging bonds. The molecule has two such bridging **three-center bonds** (8).



8 A three-center bond

Thinking point: Why are three-center bonds characteristic of boron and not other elements?

Self-Test 15.9A Compare the reactions for the formation of BF_3 and BCl_3. Which reaction is a redox reaction?

[***Answer:*** The formation of BCl_3]

Self-Test 15.9B What is the oxidation number of boron in (a) $NaBH_4$; (b) $H_2BO_3^-$?

The boranes are an extensive series of highly reactive electron-deficient binary compounds of boron and hydrogen. Borohydrides are useful reducing agents.

GROUP 14/IV: THE CARBON FAMILY

Carbon is central to life and natural intelligence. Silicon and germanium are central to electronic technology and artificial intelligence (Fig. 15.27). The unique properties of Group 14/IV elements make both types of intelligence possible. The half-filled valence shell of these elements gives them special properties that straddle the line between metals and nonmetals. Carbon, at the head of the group, forms so many compounds that it has its own branch of chemistry, organic chemistry (Chapters 18 and 19).

15.12 The Group 14/IV Elements

The valence electron configuration is ns^2np^2 for all members of the group. All four electrons are approximately equally available for bonding in the lighter elements, and carbon and silicon are characterized by their ability to form four covalent bonds. However, as in Group 13/III, the heavier elements display the inert-pair effect. On descending the group, the energy separation between the s- and p-orbitals increases and the s-electrons become progressively less available for bonding; in fact, the most common oxidation number for lead is +2.

The elements show increasing metallic character down the group (Table 15.6). Carbon has definite nonmetallic properties: it forms covalent compounds with nonmetals and ionic compounds with metals. The oxides of carbon and silicon are acidic.

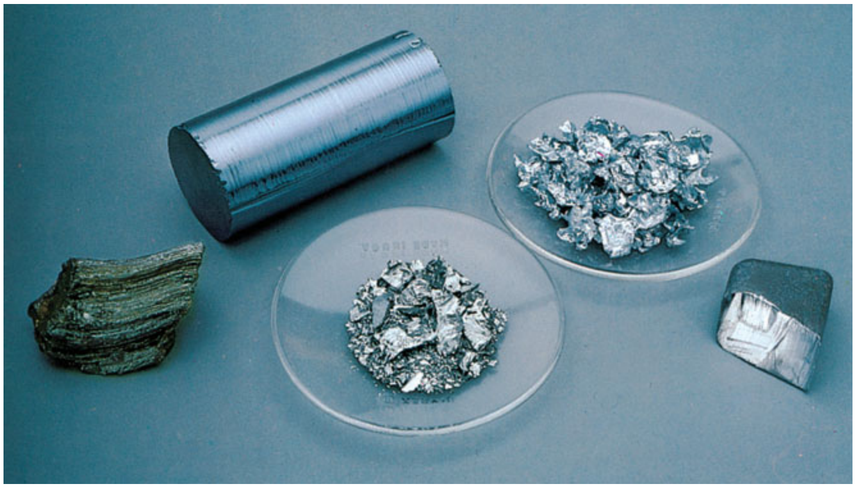


FIGURE 15.27 The elements of Group 14/IV. Back row, from left to right: silicon; tin. Front row: carbon (graphite); germanium; lead.

TABLE 15.6 Group 14/IV Elements

Valence configuration: ns^2np^2

Z	Name	Symbol	Molar mass ($g\cdot mol^{-1}$)	Melting point (°C)	Boiling point (°C)	Density ($g\cdot cm^{-3}$)	Normal form*
6	carbon	C	12.01	3370s†	—	1.9–2.3	black nonmetal (graphite)
						3.2–3.5	transparent nonmetal (diamond)
							orange nonmetal (fullerite)
14	silicon	Si	28.09	1410	2620	2.33	gray metalloid
32	germanium	Ge	72.61	937	2830	5.32	gray-white metalloid
50	tin	Sn	118.71	232	2720	7.29	white lustrous metal
82	lead	Pb	207.2	328	1760	11.34	blue-white lustrous metal

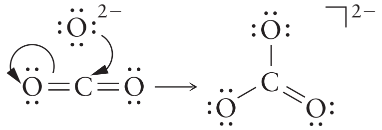
**Normal form* means the state and appearance of the element at 25°C and 1 atm.
†The symbol s denotes that the element sublimes.

Germanium is a typical metalloid in that it exhibits metallic or nonmetallic properties according to the other element present in the compound. Tin and, even more so, lead have definite metallic properties. However, even though tin is classified as a metal, it is not far from the metalloids in the periodic table, and it does have some amphoteric properties. For example, tin reacts with both hot concentrated hydrochloric acid and hot alkali:

$$Sn(s) + 2\,H_3O^+(aq) \longrightarrow Sn^{2+}(aq) + H_2(g) + 2\,H_2O(l)$$
$$Sn(s) + 2\,OH^-(aq) + 2\,H_2O(l) \longrightarrow Sn(OH)_4{}^{2-}(aq) + H_2(g)$$

Because carbon stands at the head of its group, we expect it to differ from the other members of the group. Some of the differences between carbon and silicon stem from the smaller atomic radius of carbon, which explains the wide occurrence of C=C and C=O double bonds relative to the rarity of Si=Si and Si=O double bonds. Silicon atoms are too large for the side-by-side overlap of p-orbitals necessary for π-bonds to form between them except in specially contrived arrangements in which other bridging groups of atoms press the two Si atoms together. Carbon dioxide, which consists of discrete O=C=O molecules, is a gas that we exhale. Silicon dioxide (silica), which consists of networks of —O—Si—O— groups, is a mineral that we stand on.

Silicon compounds can also act as Lewis acids, whereas carbon compounds typically cannot. Because a silicon atom is bigger than a carbon atom and can expand its valence shell by using its d-orbitals, it can accommodate the lone pair of an attacking Lewis base. A carbon atom is smaller and has no available d-orbitals; so in general it cannot act as a Lewis acid. An exception to this behavior is when the carbon atom has multiple bonds, because then a π-bond can give way to the formation of a σ-bond, as in the reaction between CO_2 and O^{2-} to form $CO_3{}^{2-}$:



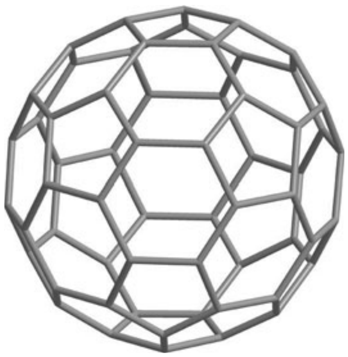
Solid carbon exists as graphite, diamond, and other phases such as the fullerenes, which have structures related to that of graphite. Graphite is the thermodynamically most stable of these allotropes under ordinary conditions. In Chapter 6, we saw how the properties of the different allotropes of carbon are related to differences in bonding. Here we give an overview of the various allotropes and their properties.

Coke is an impure form of carbon obtained from the solid residue remaining after the destructive distillation of coal; because it is inexpensive, it is used extensively in steel production. *Soot* and *carbon black* contain very small crystals of graphite and other forms of carbon. Carbon black, which is produced by heating gaseous hydrocarbons to nearly 1000°C in the absence of air, is used for reinforcing rubber, for pigments,

and for printing inks, such as the ink on this page. *Activated carbon*, which is also called *activated charcoal*, consists of granules of microcrystalline carbon. It is produced by heating waste organic matter in the absence of air and then processing it to increase the porosity. The very high specific surface area (as much as about 2000 $m^2 \cdot g^{-1}$) of the porous carbon enables it to remove organic impurities from liquids and gases by adsorption. It is used in air purifiers, gas masks, and aquarium water filters. On a larger scale, activated carbon is used in water purification plants to remove organic compounds from drinking water.

Graphite consists of planar graphene sheets of sp^2 hybridized carbon atoms in a hexagonal network (recall Fig. 6.9). The graphite found in nature is the result of changes in ancient organic remains. Pure graphite is produced in industry by passing a heavy electric current through rods of coke. In diamond, each carbon atom is sp^3 hybridized and linked tetrahedrally to its four neighbors, with all electrons in C—C σ-bonds (recall Fig. 6.10).

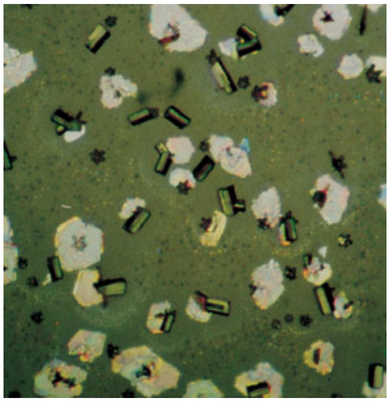
Chemists were greatly surprised when soccer-ball-shaped carbon molecules were first identified in 1985, particularly because they might be even more abundant than graphite and diamond! The C_{60} molecule (**9**) is named buckminsterfullerene after the American architect R. Buckminster Fuller, whose geodesic domes it resembles. Within 2 years, scientists had succeeded in making crystals of buckminsterfullerene; the solid samples are called *fullerite* (Fig. 15.28). The discovery of this molecule and others with similar structures, such as C_{70}, opened up the prospect of a whole new field of chemistry. For instance, the interior of a C_{60} molecule is big enough to hold an atom of another element, and chemists are now busily preparing a whole new periodic table of these shrink-wrapped atoms.



9 Buckminsterfullerene, C_{60}

The *fullerenes* are members of the family of molecules resembling (and including) buckminsterfullerene. They are formed in smoky flames and by red giants (stars with low surface temperatures and large diameters), and so the universe might contain huge numbers of them. Graphite and diamond are network solids that are insoluble in all liquid solvents except some liquid metals. However, the fullerenes, which are molecular, can be dissolved by suitable solvents (such as benzene); buckminsterfullerene itself forms a red-brown solution. Fullerite currently has few uses, but some of the compounds of the fullerenes have great promise. For example, K_3C_{60} is a superconductor below 18 K, and other fullerene compounds appear to be active against cancer and diseases such as AIDS.

Carbon nanotubes consist of concentric tubes with walls like graphene sheets rolled into cylinders. These tiny structures form strong, conducting fibers with a large surface area. As a consequence, they have unusually interesting and promising properties that have become a major thrust of nanotechnology research. Section 6.19 describes some of the applications of nanomaterials produced when carbon and silicon are coaxed into desired configurations and Box 15.2 describes materials that result when molecules of carbon and silicon compounds assemble themselves into organized structures.



100 μm

FIGURE 15.28 These small crystals are fullerite, in which buckminsterfullerene molecules are packed together in a close-packed lattice.

Silicon is the second most abundant element in the Earth's crust. It occurs widely in rocks as *silicates*, compounds containing the silicate ion, SiO_3^{2-}, and as the silica, SiO_2, of sand (Section 6.7). Pure silicon is obtained from *quartzite*, a granular form of *quartz* (another solid phase of SiO_2), by reduction with high-purity carbon in an electric arc furnace:

$$SiO_2(s) + 2\,C(s) \xrightarrow{\Delta} Si(s) + 2\,CO(g)$$

The crude product is exposed to chlorine to form silicon tetrachloride, which is then distilled and reduced with hydrogen to a purer form of the element:

$$SiCl_4(l) + 2\,H_2(g) \longrightarrow Si(s) + 4\,HCl(g)$$

Further purification is necessary before silicon can be used in semiconductors. In one process, a large single crystal is grown by pulling a solid rod of the element slowly from the melt. The silicon is then purified by **zone refining,** in which a hot, molten zone is

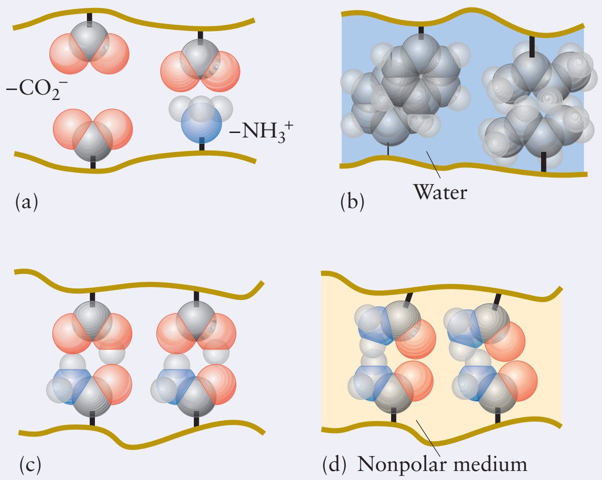
BOX 15.2 FRONTIERS OF CHEMISTRY: SELF-ASSEMBLING MATERIALS

A major concern of scientists working with nanomaterials is how to coax molecules into organizing themselves into the desired nanoscale arrangements. Many biological processes operate at the nanoscale level. Proteins, for example, fold up into the shape that optimizes their function (see Section 19.13), cell membranes form spontaneously when certain molecules called lipids encounter water (see Box 9.1), and the DNA molecules of our genes replicate themselves every time a cell divides. Although the expression has a variety of definitions, the common meaning of *self-assembly of molecules* is the spontaneous formation of organized structures from individual parts.

Self-assembly can be static or dynamic. In *static self-assembly*, the structure formed is stable and the process does not readily reverse. Two examples are the folding of polypeptide chains into a protein molecule and the formation of the double helix of DNA. *Dynamic self-assembly* involves interactions that dissipate energy and can easily be reversed. Two examples are oscillating chemical reactions and convection patterns. On the macroscopic scale, the coordinated motion of a school of fish or a flock of migrating birds is regarded as an example of dynamic self-assembly. However, the most promising area of self-assembly is in the intermediate realm between molecular and macroscopic, where it may become possible to design nanoscale sensors and machines to carry out specific tasks. In general, we can take advantage of self-assembly only where it already exists in nature. However, designing materials that can assemble themselves is a strategy that is beginning to result in materials that can respond to stimuli and act in seemingly intelligent ways.

You might be using a self-assembled material the next time you use in-line skates. One brand of these skates contains a "smart gel" that is a liquid at normal temperatures but assembles itself into a firm, rubbery gel when exposed to body temperature. The gel fills the space between the lining of the skate boot and the sides and, once the skate has been secured, it sets to conform to the exact shape of the foot. Such a gel generally consists of an aqueous suspension of organic molecules with long chains containing different regions, some of which have strong intermolecular forces and some of which have weak intermolecular forces. The temperature determines how the chains are coiled. At low temperatures, the regions with strong intermolecular forces are turned inward, and so the molecules remain in liquid solution. However, at higher temperatures,

In the Belousov–Zhabotinskii reaction, beautiful regular patterns form spontaneously as the result of the oscillating concentrations of reactants and products due to competing reactions.



These four types of forces are responsible for the adaptive behavior of smart gels. The different forces come into play when the network of polymer chains composing a gel is disturbed. (a) Charged ionic regions can attract or repel each other. (b) Nonpolar hydrophobic regions exclude water. (c) Hydrogen bonds may form from one chain to another. (d) Dipole–dipole interactions can attract or repel chains.

those regions are turned outward, where they can attract other chains to form a flexible, but firm, network.

Another type of gel expands and contracts as its structure changes in response to electrical signals and is being investigated for use in artificial limbs that would respond and feel like real ones. One material being studied for use in artificial muscle contains a mixture of polymers, silicone oil (a polymer with a $-(\!-O-Si-O-Si-)_n-$ backbone and hydrocarbon side chains), and salts. When exposed to an electric field, the molecules of the soft gel rearrange themselves so that the material contracts and stiffens. If struck, the stiffened material can break but, on softening, the gel is reformed. The transition between gel and solid state is therefore reversible.

? HOW MIGHT YOU CONTRIBUTE?

The properties of self-assembled materials need to be studied and categorized. For example, how do molecules recognize one another in a mixture? In addition, strategies to promote self-assembly need to be designed. Simple two-dimensional assemblies have been created, and these techniques need to be expanded to three dimensions. Applications are emerging in nanotechnology, in the fields of microelectronics and robotics, and in medicine, where biosensor arrays have shown high selectivity for individual toxins and bioagents.

Service, "How far can we push chemical self-assembly?" *Science*, vol. 309, 2005, p. 95. G. Whitesides and B. Grzybowski, "Self-assembly at all scales," *Science*, vol. 295, March 29, 2002, pp. 2418–2421.

dragged from one end of a cylindrical sample to the other, collecting impurities as it goes (Fig. 15.29). The result is "ultrapure" silicon, which has fewer than one impurity atom per billion Si atoms. An alternative technique is the decomposition of silane, SiH_4, by an electric discharge. This method produces an amorphous form of silicon with a significant hydrogen content. *Amorphous silicon* is used in photovoltaic devices, which produce electricity from sunlight.

Germanium was not known until 1886 and has the distinction of having been predicted by Mendeleev before it was discovered (see Box 1.2). It is recovered from the flue dust of industrial plants processing zinc ores (in which it occurs as an impurity). It is used mainly—and increasingly—in the semiconductor industry to create very fast integrated circuits.

Tin and lead are obtained very easily from their ores and have been known since antiquity. Tin occurs chiefly as the mineral *cassiterite*, SnO_2, and is obtained from it by reduction with carbon at 1200°C:

$$SnO_2(s) + C(s) \xrightarrow{1200°C} Sn(l) + CO_2(g)$$

The principal lead ore is *galena*, PbS. It is roasted in air, which converts it into PbO, and this oxide is then reduced with coke:

$$2\,PbS(s) + 3\,O_2(g) \xrightarrow{\Delta} 2\,PbO(s) + 2\,SO_2(g)$$
$$PbO(s) + C(s) \longrightarrow Pb(s) + CO(g)$$

Tin is expensive and not very strong, but it is resistant to corrosion. Its main use is in tinplating, which accounts for about 40% of its consumption. Tin is also used in alloys such as bronze (mostly copper, with about 2–10% tin) and pewter (about 91% or more tin, with antimony, copper, and for some applications lead or bismuth).

Lead's durability (its chemical inertness) and malleability make it useful in the construction industry. The inertness of lead under normal conditions can be traced to the passivation of its surface by oxides, chlorides, and sulfates (see Section 13.14). Passivated lead containers can be used for transporting hot concentrated sulfuric acid but not nitric acid, because lead nitrate is soluble. Another important property of lead is its high density, which makes it useful as a radiation shield because its numerous electrons absorb high-energy radiation. Lead was once commonly used in leaded gasoline (as tetraethyl lead, $Pb(CH_2CH_3)_4$), but lead is a toxic heavy metal and that usage has declined as concern for the amount of lead in the environment has increased. The main use of lead today is for the electrodes of rechargeable storage batteries (see Section 13.15).

Metallic character increases significantly down Group 14/IV. Carbon is the only member of Group 14/IV that commonly forms multiple bonds with itself; singly bonded silicon atoms can act as Lewis acids because a silicon atom can expand its valence shell. Carbon has an important series of allotropes: diamond, graphite, and the fullerenes.

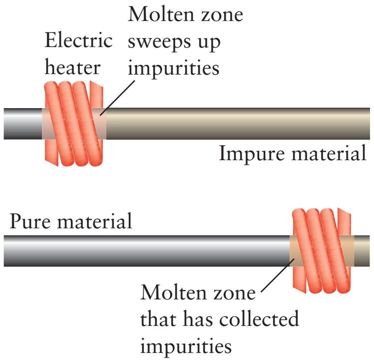

FIGURE 15.29 In the technique of zone refining, a molten zone is passed repeatedly from one end of the solid sample to the other. The impurities collect in the zone and move along the solid with the heater, leaving a pure substance behind.

15.13 Oxides of Carbon and Silicon

We have already met carbon dioxide, CO_2, many times throughout this book. It is formed when organic matter burns in a plentiful supply of air and during animal respiration. It is normally present in the atmosphere; but there is widespread and well-founded concern that an increase in atmospheric carbon dioxide due to the combustion of fossil fuels is contributing to global warming (see Box 15.1).

Carbon dioxide is the acid anhydride of carbonic acid, H_2CO_3, which forms when the gas dissolves in water. However, not all the dissolved molecules react to form the acid, and a solution of carbon dioxide in water is an equilibrium mixture of CO_2, H_2CO_3, HCO_3^-, and a very small amount of CO_3^{2-}. Carbonated beverages are made by using high partial pressures of CO_2 to produce high concentrations of carbon dioxide in water. When the partial pressure of the CO_2 is reduced by removing a bottle cap or the seal, the equilibrium $H_2CO_3(aq) \rightleftharpoons CO_2(g) + H_2O(l)$ shifts from H_2CO_3 toward CO_2 and the liquid effervesces.

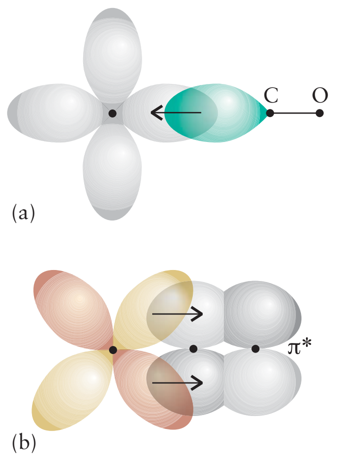

FIGURE 15.30 Carbon monoxide can bind to a d-metal atom in two ways: (a) by using the lone pair on the C atom to form a σ-bond or (b) by using one of its empty antibonding π-orbitals to accept electrons donated from a d-orbital on the metal atom.

Carbon monoxide, CO, is produced when carbon or organic compounds burn in a limited supply of air, as happens in cigarettes and badly tuned automobile engines. It is produced commercially as a component of synthesis gas by the re-forming reaction (Section 15.3). Carbon monoxide is the formal anhydride of formic acid, HCOOH, and the gas can be produced in the laboratory by the dehydration of formic acid with hot, concentrated sulfuric acid:

$$HCOOH(l) \xrightarrow{150°C,\ H_2SO_4} CO(g) + H_2O(l)$$

Although the reverse of this reaction cannot be carried out directly, carbon monoxide does react with hydroxide ions in hot alkali to produce formate ions:

$$CO(g) + OH^-(aq) \longrightarrow HCO_2^-(aq)$$

Carbon monoxide is a colorless, odorless, flammable, almost insoluble, very toxic gas that condenses to a colorless liquid at −90°C. It is not very reactive, largely because its bond enthalpy (1074 $kJ\cdot mol^{-1}$) is higher than that of any other molecule. However, it is a Lewis base, and the lone pair on the carbon atom forms covalent bonds with d-block atoms and ions. Carbon monoxide is also a Lewis acid, because its empty antibonding π-orbitals can accept electron density from a metal (Fig. 15.30). This dual character makes carbon monoxide very useful for forming complexes, and numerous metal carbonyls are known (see Section 16.3). Complex formation is also responsible for carbon monoxide's toxicity: it attaches more strongly than oxygen to the iron in hemoglobin and prevents it from accepting oxygen from the air in the lungs. As a result, the victim suffocates.

Because it can be further oxidized, carbon monoxide is a reducing agent. It is used in the production of a number of metals, most notably iron in blast furnaces (Section 16.3):

$$Fe_2O_3(s) + 3\ CO(g) \xrightarrow{\Delta} 2\ Fe(l) + 3\ CO_2(g)$$

Silica, SiO_2, is a hard, rigid network solid that is insoluble in water. It occurs naturally as quartz and as sand, which consists of small fragments of quartz, usually colored golden brown by iron oxide impurities. Some precious and semiprecious stones are impure silica (Fig. 15.31). *Flint* is silica colored black by carbon impurities. The structures and uses of some of the silicates are described in Section 6.7.

Metasilicic acid, H_2SiO_3, and *orthosilicic acid*, H_4SiO_4, are weak acids. However, when a solution of sodium orthosilicate is acidified, instead of H_4SiO_4, a gelatinous precipitate of silica is produced:

$$4\ H_3O^+(aq) + SiO_4^{4-}(aq) + x\ H_2O(l) \longrightarrow SiO_2(s)\cdot xH_2O(gel) + 6\ H_2O(l)$$

After it is washed, dried, and granulated, this *silica gel* has a very high specific surface area (about 700 $m^2\cdot g^{-1}$) and is useful as a drying agent, a support for catalysts, a packing for chromatography columns, and a thermal insulator.

FIGURE 15.31 Some impure forms of silica that are semiprecious stones: amethyst (left), in which the color is due to Fe^{3+} impurities; agate (center); and onyx (right).

Self-Test 15.10A What is (a) the oxidation number and (b) the formal charge of carbon in CO (use the Lewis structure :C≡O:)?

[***Answer:*** (a) +2; (b) −1.]

Self-Test 15.10B What type of reaction is the reaction of carbon monoxide with hydroxide ion?

Carbon has two important oxides: carbon dioxide and carbon monoxide. The former is the acid anhydride of carbonic acid, the parent acid of the hydrogen carbonates and the carbonates. Silica is a hard network material. The silicic acids are weak acids.

15.14 Other Important Group 14/IV Compounds

Carbon is the only Group 14/IV element that forms both monatomic and polyatomic anions. There are three classes of carbides: saline carbides (saltlike carbides), covalent carbides, and interstitial carbides. Covalent and interstitial carbides, which are important industrial materials, were discussed in Section 6.9.

The *saline carbides* are formed most commonly from the metals of Groups 1 and 2, aluminum, and a few other metals. The s-block metals form saline carbides when their oxides are heated with carbon. The anions present in saline carbides are either C_2^{2-} or C^{4-}. All the C^{4-} carbides, which are called *methides*, produce methane and the corresponding hydroxide in water:

$$Al_4C_3(s) + 12\,H_2O(l) \longrightarrow 4\,Al(OH)_3(s) + 3\,CH_4(g)$$

This reaction shows that the methide ion is a very strong Brønsted base. The species C_2^{2-} is the *acetylide ion*, and the carbides that contain it are called *acetylides*. The acetylide ion is also a strong Brønsted base, and acetylides react with water to produce ethyne (acetylene) and the corresponding hydroxide. Calcium carbide, CaC_2, is the most common saline carbide. It was once used in miners' lanterns, in which water from a reservoir was allowed to drip slowly on to chunks of calcium carbide. The acetylene produced was then burned for the light it created.

All Group 14/IV elements form liquid molecular tetrachlorides. The least stable is $PbCl_4$, which decomposes to solid $PbCl_2$ when it is warmed to about 50°C. Carbon tetrachloride, CCl_4 (tetrachloromethane), was widely used as an industrial solvent; however, now that it is known to be carcinogenic, it is used primarily as the starting point for the manufacture of chlorofluorocarbons. Carbon tetrachloride is formed by the action of chlorine on methane:

$$CH_4(g) + 4\,Cl_2(g) \xrightarrow{\Delta} CCl_4(g, \text{l when cooled}) + 4\,HCl(g)$$

Silicon reacts directly with chlorine to form silicon tetrachloride, $SiCl_4$ (this reaction was introduced in Section 15.12, as one step in the purification of silicon). This compound differs strikingly from CCl_4 in that it reacts readily with water as a Lewis acid, accepting a lone pair of electrons from H_2O:

$$SiCl_4(l) + 2\,H_2O(l) \longrightarrow SiO_2(s) + 4\,HCl(aq)$$

The cyanide ion, CN^-, is the conjugate base of hydrogen cyanide, HCN. This acid is made by heating ammonia, methane, and air in the presence of a platinum catalyst:

$$2\,CH_4(g) + 2\,NH_3(g) + 3\,O_2(g) \xrightarrow{1100°C,\ Pt} 2\,HCN(g) + 6\,H_2O(g)$$

Cyanides are strong Lewis bases that form a range of complexes with d-block metal ions. They are also famous as poisons. When they are ingested, they combine with certain protein molecules—the cytochromes—involved in the transfer of electrons and the supply of energy in cells, and the victim dies.

Because carbon bonds so readily with itself, there are huge numbers of hydrocarbons (see Chapter 18). Silicon forms a much smaller number of compounds with hydrogen, called the *silanes*. The simplest silane is silane itself, SiH_4, the analog of methane. Silane is formed by the action of lithium aluminum hydride on silicon halides in ether:

$$SiCl_4 + LiAlH_4 \longrightarrow SiH_4 + LiCl + AlCl_3$$

Silane is much more reactive than methane and bursts into flame on contact with air. Although it survives in pure water, it forms SiO_2 when a trace of alkali is present:

$$SiH_4(g) + 2\,H_2O(l) \xrightarrow{OH^-} SiO_2(s) + 4\,H_2(g)$$

The more complicated silanes, such as $SiH_3{-}SiH_2{-}SiH_3$, the analog of propane, decompose on standing.

Thinking point: Is the existence of alien life-forms based on silicon plausible?

Self-Test 15.11A Both carbide ions, C_2^{2-} and C^{4-}, react as bases with water. Predict which carbide ion is the stronger base. Explain your answer.

[***Answer:*** The C^{4-} ion, because it has a higher negative charge.]

Self-Test 15.11B Explain the fact that SiH_4 reacts with water containing OH^- ions but CH_4 does not.

Carbon forms ionic carbides with the metals of Groups 1 and 2. Silicon compounds are more reactive than carbon compounds. They can act as Lewis acids.

GROUP 15/V: THE NITROGEN FAMILY

Atoms of the Group 15/V elements have the valence electron configuration ns^2np^3 (Table 15.7). The chemical and physical properties of the elements vary sharply in this group, from the almost unreactive gas nitrogen, through the soft nonmetal phosphorus, which is so reactive that it ignites in air, to the important semiconducting materials arsenic and antimony and the largely metallic bismuth (Fig. 15.32). The range of oxidation states for Group 15/V elements is from −3 to +5, but only nitrogen and phosphorus are found in each oxidation state. Metallic character increases down the group, but the only element considered to be metallic is bismuth, at the bottom of Group 15/V. Arsenic and antimony are metalloids.

TABLE 15.7 The Group 15/V Elements

Valence configuration: ns^2np^3

Z	Name	Symbol	Molar mass ($g{\cdot}mol^{-1}$)	Melting point (°C)	Boiling point (°C)	Density ($g{\cdot}cm^{-3}$)	Normal form*

15.15 The Group 15/V Elements

Nitrogen is rare in the Earth's crust, but elemental nitrogen is the principal component of our atmosphere (76% by mass). Pure nitrogen gas is obtained by the fractional distillation of liquid air. Air is cooled to below −196°C by repeated expansion and compression in a refrigerator like that described in Section 4.13. The liquid mixture is then warmed, and the nitrogen (b.p. −196°C) boils off while most of the argon (b.p. −186°C) and oxygen (b.p. −183°C) remain liquid. Nitrogen gas produced industrially is used primarily as a raw material for the synthesis of ammonia in the Haber process.

Lavoisier named the element *azote*, which means "lifeless." Ironically, we now know that there would be no life as we know it without nitrogen.

Plants need nitrogen to grow. However, they cannot use N_2 directly, because the strength of the N≡N bond (944 $kJ\cdot mol^{-1}$) makes nitrogen gas almost as inert as the noble gases. To be available for organisms, nitrogen must first be "fixed," or combined with other elements into more useful compounds. Once fixed, nitrogen can be converted into compounds for use as medicines, fertilizers, explosives, and plastics. Lightning converts some nitrogen into its oxides, which dissolve in rain and are then washed into the soil. Some bacteria also fix nitrogen in nodules on the roots of clover, beans, peas, alfalfa, and other legumes (Fig. 15.33). An intensely active field of research is the search for catalysts that can mimic these bacteria and fix nitrogen at ordinary temperatures. At present, the Haber synthesis of ammonia is the main industrial route for fixing nitrogen, but it requires costly high pressures (see Section 10.10).

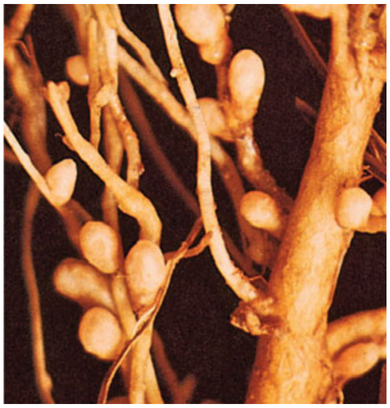

FIGURE 15.33 The bacteria that inhabit these nodules on the roots of a pea plant are responsible for fixing atmospheric nitrogen and making it available to the plant.

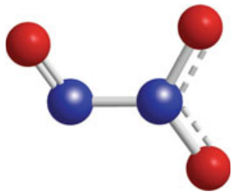
Like other elements at the head of a group, nitrogen differs in many ways from its congeners. For example, nitrogen is highly electronegative ($\chi = 3.0$, about the same as for chlorine). Because of its high electronegativity, nitrogen is the only element in Group 15/V that forms hydrides capable of hydrogen bonding. Because its atoms are small, nitrogen can form multiple bonds with other Period 2 atoms by using its p-orbitals.

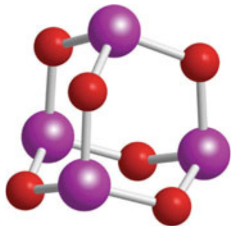
As we shall see, its small size and the unavailability of d-orbitals account for many of the differences between the chemical and physical properties of nitrogen and those of its congeners. Another important chemical property of nitrogen is its wide range of oxidation numbers: compounds are known for each whole-number oxidation state from −3 (in NH_3) to +5 (in nitric acid and the nitrates). Nitrogen also occurs with fractional oxidation numbers, such as $-\frac{1}{3}$ in the azide ion, N_3^-.

The name phosphorus means "light bringer."

The properties of phosphorus, in Period 3, differ significantly from those of nitrogen. The atomic radius of phosphorus is nearly 50% larger than that of nitrogen, and so two phosphorus atoms are too big to approach each other closely enough for their 3p-orbitals to overlap and form π-bonds. Thus, whereas nitrogen can form multiply bonded structures such as N_2O_3 (**10**), phosphorus forms additional single bonds, as in P_4O_6 (**11**). The size of its atoms and the availability of 3d-orbitals means that phosphorus can form as many as six bonds (as in PCl_6^-), whereas nitrogen can form only four (see Section 2.10).



10 Dinitrogen trioxide, N_2O_3

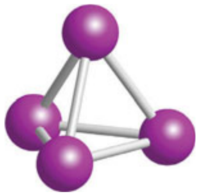


11 Phosphorus(III) oxide, P_4O_6

Phosphorus is obtained from the *apatites*, which are mineral forms of calcium phosphate, $Ca_3(PO_4)_2$. The rocks are heated in an electric furnace with carbon and sand:

$$2\,Ca_3(PO_4)_2(s) + 6\,SiO_2(s) + 10\,C(s) \xrightarrow{\Delta} P_4(g) + 6\,CaSiO_3(l) + 10\,CO(g)$$

The phosphorus vapor condenses as *white phosphorus*, a soft, white, poisonous molecular solid consisting of tetrahedral P_4 molecules (**12**). This allotrope is highly reactive, in part because of the strain associated with the 60° angles between the bonds. It is very dangerous to handle because it bursts into flame on contact with air and can cause severe burns. White phosphorus is normally stored under water. It changes into *red phosphorus* when heated in the absence of air. Red phosphorus is less reactive than the white allotrope; however, it can be ignited by friction and is used in the striking surfaces of matchbooks. The friction created by rubbing a match across the surface ignites the phosphorus, which, in turn, lights the highly flammable material in the match head. Red phosphorus is thought to consist of chains of linked P_4 tetrahedra.



12 Phosphorus, P_4

Vapor rising from white phosphorus in moist air glows with a yellow-green light. The oxides produced by the reaction of phosphorus with the oxygen in air are formed in electronically excited states, and light is given off as electrons fall back into the ground state in the process called chemiluminescence (Section 6.15).

FIGURE 15.34 The minerals (from left to right) orpiment, As_2S_3; stibnite, Sb_2S_3; and realgar, As_4S_4; are all ores that have been used as sources of Group 15/V elements.

Arsenic and antimony are metalloids. They have been known in the pure state since ancient times because they are easily obtained from their ores (Fig. 15.34). In the elemental state, they are used primarily in the semiconductor industry and in the lead alloys used as electrodes in storage batteries. Gallium arsenide is used in lasers, including the lasers used in CD players. Metallic bismuth, with its large, weakly bonded atoms, has a low melting point and is used in alloys that serve as fire detectors in sprinkler systems: the alloy melts when a fire breaks out nearby, and the sprinkler system is activated. Like ice, solid bismuth is less dense than the liquid. As a result, molten bismuth does not shrink when it solidifies in molds, and so it is used to make low-temperature castings.

Nitrogen is highly unreactive as an element, largely because of its strong triple bond. White phosphorus is highly reactive. The differences in properties between the nonmetals nitrogen and phosphorus can be traced to the larger atomic radius and lower electronegativity of phosphorus and the availability of d-orbitals in its valence shell. Metallic character increases down the group.

15.16 Compounds with Hydrogen and the Halogens

The pungency of heated ammonium chloride was known in antiquity to the Ammonians, the worshippers of the Egyptian god Ammon.

By far the most important hydrogen compound of a Group 15/V element is ammonia, NH_3, which is prepared in huge amounts by the Haber process. Small quantities of ammonia are present naturally in the atmosphere as a result of the bacterial decomposition of organic matter in the absence of air. This decomposition typically occurs in lake and river beds, in swamps, and in cattle feedlots.

Ammonia is a pungent, toxic gas that condenses to a colorless liquid at −33°C. The liquid resembles water in its physical properties, including its ability to act as a solvent for a wide range of substances. Because the dipole moment of the NH_3 molecule (1.47 D) is lower than that of the H_2O molecule (1.85 D), salts with strong ionic character, such as KCl, cannot dissolve in ammonia. Salts with polarizable anions tend to be more soluble in ammonia than are salts with greater ionic character. For example, iodides are more soluble than chlorides in ammonia. Liquid ammonia undergoes much less extensive autoprotolysis than water:

$$2\ NH_3(am) \rightleftharpoons NH_4^+(am) + NH_2^-(am) \qquad K_{am} = [NH_4^+][NH_2^-] = 1 \times 10^{-33} \text{ at } -35°C$$

Bases that would be fully protonated in water, such as the cyclopentadienide anion, $C_5H_5^-$, behave as very weak bases in ammonia.

Ammonia is very soluble in water because the NH_3 molecules can form hydrogen bonds to H_2O molecules. Ammonia is a weak Brønsted base in water; it is also a reasonably strong Lewis base, particularly toward d-block elements. For example, it reacts with $Cu^{2+}(aq)$ ions to give a deep-blue complex (Fig. 15.35):

$$Cu^{2+}(aq) + 4\ NH_3(aq) \longrightarrow Cu(NH_3)_4^{2+}(aq)$$

Ammonium salts decompose when heated:

$$(NH_4)_2CO_3(s) \xrightarrow{\Delta} 2\ NH_3(g) + CO_2(g) + H_2O(g)$$

The pungent smell of decomposing ammonium carbonate once made it an effective "smelling salt," a stimulant used to revive people who had fainted.

The ammonium cation of an ammonium salt may be oxidized by an anion that has oxidizing character, such as a nitrate. The products depend on the temperature of the reaction:

$$NH_4NO_3(s) \xrightarrow{250°C} N_2O(g) + 2\ H_2O(g)$$
$$2\ NH_4NO_3(s) \xrightarrow{>300°C} 2\ N_2(g) + O_2(g) + 4\ H_2O(g)$$

The explosive violence of the second reaction is the reason that ammonium nitrate is used as a component of dynamite. Ammonium nitrate has a high nitrogen content (33.5% by mass) and is highly soluble in water. These characteristics make it attractive as a fertilizer, which is its principal use.

Hydrazine, NH_2NH_2, is an oily, colorless liquid. It is prepared by the gentle oxidation of ammonia with alkaline hypochlorite solution:

$$2\ NH_3(aq) + ClO^-(aq) \xrightarrow{\text{aqueous alkali}} N_2H_4(aq) + Cl^-(aq) + H_2O(l)$$

Its physical properties are very similar to those of water; for instance, its melting point is 1.5°C and its boiling point is 113°C. However, its chemical properties are very different. It is dangerously explosive and is normally stored and used in aqueous solution. Hydrazine is used as a rocket fuel and to eliminate dissolved, corrosive oxygen from the water used in high-pressure, high-temperature steam furnaces:

$$N_2H_4(aq) + O_2(g) \longrightarrow N_2(g) + 2\ H_2O(l)$$

Nitrogen has oxidation number +3 in the highly reactive nitrogen halides. Nitrogen trifluoride, NF_3, is the most stable halide; it does not react with water. However, NCl_3 does react with water, forming ammonia and hypochlorous acid. Nitrogen triiodide, NI_3, which is known only in combination with ammonia as the "ammoniate" $NI_3{\cdot}NH_3$ (the analog of a hydrate), is so unstable that it decomposes explosively when lightly touched.

Nitrides are solids that contain the nitride ion, N^{3-}. Nitrides are stable only for small cations such as lithium or magnesium. Boron nitride, BN, is an important ceramic discussed in Section 6.9. Magnesium nitride, Mg_3N_2, is formed together with the oxide when magnesium is burned in air (Fig. 15.36):

$$3\ Mg(s) + N_2(g) \xrightarrow{\Delta} Mg_3N_2(s)$$

Magnesium nitride, like all nitrides, reacts with water to produce ammonia and the corresponding hydroxide:

$$Mg_3N_2(s) + 6\ H_2O(l) \longrightarrow 3\ Mg(OH)_2(s) + 2\ NH_3(g)$$

In this reaction, the nitride ion acts as a strong base, accepting protons from water to form ammonia.

The azide ion is a highly reactive polyatomic anion of nitrogen, N_3^-. Its most common salt, sodium azide, NaN_3, is prepared from dinitrogen oxide and molten sodium amide:

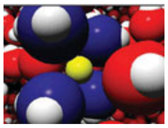
$$N_2O(g) + 2\ NaNH_2(l) \xrightarrow{175°C} NaN_3(s) + NaOH(l) + NH_3(g)$$

Sodium azide, like most azide salts, is shock sensitive. It is used in automobile air bags, where it decomposes to elemental sodium and nitrogen when detonated (see Section 4.7):

$$2\ NaN_3(s) \longrightarrow 2\ Na(s) + 3\ N_2(g)$$

The azide ion is a weak base and accepts a proton to form its conjugate acid, hydrazoic acid, HN_3. Hydrazoic acid is a weak acid similar in strength to acetic acid.

The hydrogen compounds of other members of Group 15/V are much less stable than ammonia and decrease in stability down the group. Phosphine, PH_3, is a poisonous gas that smells faintly of garlic and bursts into flame in air if it is slightly impure.



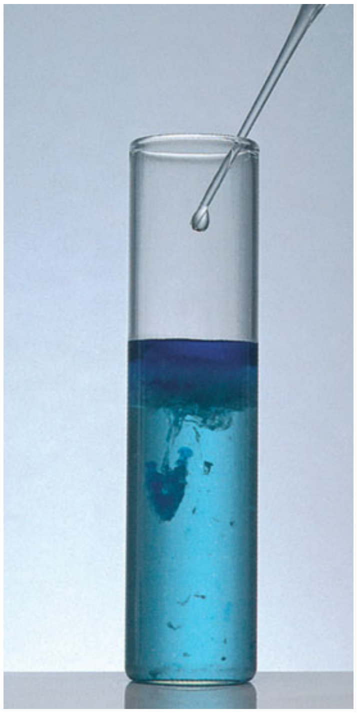


FIGURE 15.35 When aqueous ammonia is added to a copper(II) sulfate solution, first a light-blue precipitate of $Cu(OH)_2$ forms (the cloudy region at the top, which appears dark because it is backlit). The precipitate disappears when more ammonia is added to form the dark blue complex $Cu(NH_3)_4^{2+}$ by a Lewis acid–base reaction.

Animation 15.35

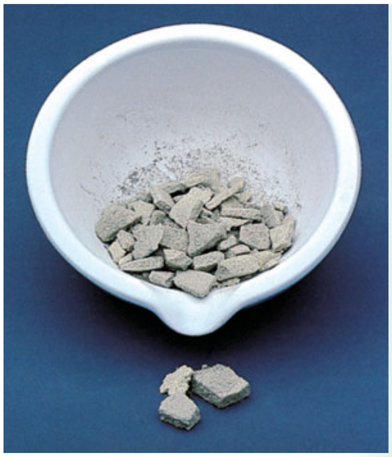

FIGURE 15.36 This sample of magnesium nitride was formed by burning magnesium in an atmosphere of nitrogen. When magnesium burns in air, the product is the oxide as well as the nitride.

Lab Video 15.36

It is much less soluble than ammonia in water because PH_3 cannot form hydrogen bonds to water. Aqueous solutions of phosphine are neutral, because the electronegativity of phosphorus is so low that the lone pair in PH_3 is spread over the hydrogen atoms as well as the phosphorus atom; consequently, the molecule has only a very weak tendency to accept a proton ($pK_b = 27.4$). Because PH_3 is the very weak parent acid of the strong Brønsted base P^{3-}, phosphine can be prepared by protonating phosphide ions with a Brønsted acid. Even water is a sufficiently strong proton donor:

$$2\,P^{3-}(s) + 6\,H_2O(l) \longrightarrow 2\,PH_3(g) + 6\,OH^-(aq)$$

Phosphorus trichloride, PCl_3, and phosphorus pentachloride, PCl_5, are the two most important halides of phosphorus. The former is prepared by direct chlorination of phosphorus. Phosphorus trichloride, a liquid, is a major intermediate for the production of pesticides, oil additives, and flame retardants. Phosphorus pentachloride, a solid, is made by allowing phosphorus trichloride to react with more chlorine (recall Fig. 2.10).

A typical reaction of the nonmetal halides is their reaction with water to give oxoacids, without a change in oxidation number:

$$PCl_3(l) + 3\,H_2O(l) \longrightarrow H_3PO_3(s) + 3\,HCl(g)$$

This reaction is an example of a **hydrolysis reaction,** a reaction with water in which new element—oxygen bonds are formed. Another example is the reaction of PCl_5 (phosphorus oxidation state +5) with water to produce phosphoric acid, H_3PO_4 (also phosphorus oxidation state +5):

$$PCl_5(s) + 4\,H_2O(l) \longrightarrow H_3PO_4(l) + 5\,HCl(g).$$

This reaction is violent and dangerous.

An interesting feature of phosphorus pentachloride is that it is an ionic solid of tetrahedral PCl_4^+ cations and octahedral PCl_6^- anions, but it vaporizes to a gas of trigonal bipyramidal PCl_5 molecules (see Section 2.10). Phosphorus pentabromide is also molecular in the vapor and ionic as the solid; but, in the solid, the anions are simply Br^- ions, presumably because six bulky Br atoms simply do not fit around a central P atom.

Self-Test 15.12A Propose an explanation for the fact that the nitrogen trihalides become less stable as the molar mass of the halogen increases.

[***Answer:*** The N atom is small; as the molar mass of the halogen increases, fewer can fit easily around it.]

Self-Test 15.12B (a) Write the Lewis structure for the azide ion and assign formal charges to the atoms. (b)You will find it possible to write a number of Lewis structures. Which is likely to make the biggest contribution to the resonance? (c) Predict the shape of the ion and its polarity.

The important compounds of nitrogen with hydrogen are ammonia, hydrazine, and hydrazoic acid, the parent of the shock-sensitive azides. Phosphine forms neutral solutions in water; reaction of phosphorous halides with water produces oxoacids without change in oxidation number.

15.17 Nitrogen Oxides and Oxoacids

Nitrogen forms several oxides, with oxidation numbers ranging from +1 to +5. All nitrogen oxides are acidic oxides and some are the acid anhydrides of the nitrogen oxoacids (Table 15.8). In atmospheric chemistry, where the oxides play an important two-edged role in both maintaining and polluting the atmosphere, they are referred to collectively as NO_x (read "nox").

Dinitrogen oxide, N_2O (oxidation number +1), is commonly called nitrous oxide. It is formed by heating ammonium nitrate gently:

$$NH_4NO_3(s) \xrightarrow{250^\circ C} N_2O(g) + 2\,H_2O(g)$$

Like many of the reactions in this book, this reaction is extremely hazardous. Don't try it.

TABLE 15.8 The Oxides and Oxoacids of Nitrogen

Oxidation number	Oxide formula	Oxide name	Oxoacid formula	Oxoacid name
5	N_2O_5	dinitrogen pentoxide	HNO_3	nitric acid
4	NO_2*	nitrogen dioxide	—	
	N_2O_4	dinitrogen tetroxide	—	
3	N_2O_3	dinitrogen trioxide	HNO_2	nitrous acid
2	NO	nitrogen monoxide nitric oxide	—	
1	N_2O	dinitrogen monoxide nitrous oxide	$H_2N_2O_2$	hyponitrous acid

*$2\ NO_2 \rightleftharpoons N_2O_4$.

Because it is tasteless, unreactive, nontoxic in small amounts, and soluble in fats, N_2O is sometimes used as a foaming agent and propellant for whipped cream.

Nitrogen oxide (or nitrogen monoxide), NO (oxidation number +2), is commonly called nitric oxide. It is a colorless gas prepared industrially by the catalytic oxidation of ammonia:

$$4\ NH_3(g) + 5\ O_2(g) \xrightarrow{1000°C,\ Pt} 4\ NO(g) + 6\ H_2O(g)$$

In the laboratory, nitrogen oxide can be prepared by reducing a nitrite with a mild reducing agent such as I^-:

$$2\ NO_2^-(aq) + 2\ I^-(aq) + 4\ H^+(aq) \longrightarrow 2\ NO(g) + I_2(aq) + 2\ H_2O(l)$$

Thinking point: Why can a strong reducing agent not be used?

Nitrogen oxide is rapidly oxidized to nitrogen dioxide on exposure to air, a reaction that contributes to acid rain (see Box 11.1):

$$2\ NO(g) + O_2(g) \longrightarrow 2\ NO_2(g)$$

Nitrogen oxide plays both harmful and beneficial roles in our lives. The conversion of atmospheric nitrogen into NO in hot airplane and automobile engines contributes to the problem of acid rain and the formation of smog, as well as to the destruction of the ozone layer (see Box 14.3). However, in small amounts in the body, nitrogen oxide acts as a neurotransmitter, helps to dilate blood vessels, and participates in other physiological changes. It is a subtle neurotransmitter because it is highly mobile, on account of its small size, but is quickly destroyed, on account of being a radical.

Nitrogen dioxide, NO_2 (oxidation number +4), is a choking, poisonous, brown gas that contributes to the color and odor of smog. The molecule has an odd number of electrons, and in the gas phase it exists in equilibrium with its colorless dimer N_2O_4. Only the dimer exists in the solid phase, and so the brown gas condenses to a colorless solid. When it dissolves in water, NO_2 disproportionates into nitric acid (oxidation number +5) and nitrogen oxide (oxidation number +2):

$$3\ NO_2(g) + H_2O(l) \longrightarrow 2\ HNO_3(aq) + NO(g)$$

Nitrogen dioxide in the atmosphere undergoes the same reaction and contributes to the formation of acid rain. It also initiates a complex sequence of smog-forming photochemical reactions.

The blue gas dinitrogen trioxide, N_2O_3 (Fig. 15.37, **10**), in which the oxidation number of nitrogen is +3, is the anhydride of nitrous acid, HNO_2, and forms that acid when it dissolves in water:

$$N_2O_3(g) + H_2O(l) \longrightarrow 2\ HNO_2(aq)$$

Nitrous acid, the parent acid of the nitrites, has not been isolated in pure form but is widely used in aqueous solution. Nitrites are produced by the reduction of nitrates with hot metal:

$$KNO_3(s) + Pb(s) \xrightarrow{350°C} KNO_2(s) + PbO(s)$$

FIGURE 15.37 Dinitrogen trioxide, N_2O_3, condenses to a deep-blue liquid that freezes at –100°C to a pale-blue solid, as shown here. On standing, it turns green as a result of partial decomposition into nitrogen dioxide, a yellow-brown gas.

Most nitrites are soluble in water and mildly toxic. Despite their toxicity, nitrites are used in the processing of meat products because they retard bacterial growth and form a pink complex with myoglobin that inhibits the oxidation of blood (a reaction that would otherwise turn the meat brown). Nitrites are responsible for the pink color of ham, sausages, and other cured meat.

Nitric acid, HNO_3 (oxidation number +5) is used extensively in the production of fertilizers and explosives. It is made by the three-step *Ostwald process:*

Step 1 Oxidation of ammonia; nitrogen's oxidation number increases from −3 to +2:

$$4\,\overset{-3}{N}H_3(g) + 5\,O_2(g) \xrightarrow{350°C,\ 5\ atm,\ Pt/Rh} 4\,\overset{+2}{N}O(g) + 6\,H_2O(g)$$

Step 2 Oxidation of nitrogen oxide; nitrogen's oxidation number increases from +2 to +4:

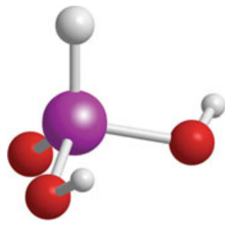
$$2\,\overset{+2}{N}O(g) + O_2(g) \longrightarrow 2\,\overset{+4}{N}O_2(g)$$

Step 3 Disproportionation in water; nitrogen's oxidation number changes from +4 to +5 and +2:

$$3\,\overset{+4}{N}O_2(g) + H_2O(l) \longrightarrow 2\,H\overset{+5}{N}O_3(aq) + \overset{+2}{N}O(g)$$

Nitric acid, a colorless liquid that boils at 83°C, is normally used in aqueous solution. Concentrated nitric acid is often pale yellow as a result of partial decomposition of the acid to NO_2. Because nitrogen has its highest oxidation number (+5) in HNO_3, nitric acid is an oxidizing agent as well as an acid. It is used to make the explosives nitroglycerin and trinitrotoluene (TNT). Much of its strength as an oxidizing agent is due to the formation of the strong bond in the N_2 molecule to which it is reduced.

Nitrogen forms oxides in each of its integer oxidation states from +1 to +5; the properties of the oxides and oxoacids are related to the oxidation number of nitrogen in the compound.



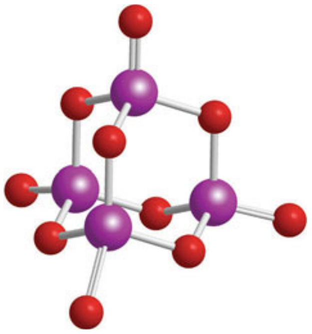
13 Phosphorous acid, H_3PO

15.18 Phosphorus Oxides and Oxoacids

The oxoacids and oxoanions of phosphorus are among the chemicals manufactured in the greatest amounts. Phosphate fertilizer production consumes two-thirds of all the sulfuric acid produced in the United States.

The structures of the phosphorus oxides are based on the tetrahedral PO_4 unit, which is similar to the structural unit in the oxides of its neighbor silicon (see Section 6.7). White phosphorus burns in a limited supply of air to form phosphorus(III) oxide, P_4O_6 (**11**):

$$P_4(s,\ white) + 3\,O_2(g) \longrightarrow P_4O_6(s)$$



14 Phosphorus(V) oxide, P_4O_{10}

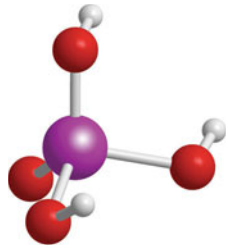
The molecules are tetrahedral, like P_4, but an O atom lies between each pair of P atoms. Phosphorus(III) oxide is the anhydride of phosphorous acid, H_3PO_3 (**13**), and is converted into the acid by cold water:

$$P_4O_6(s) + 6\,H_2O(l) \longrightarrow 4\,H_3PO_3(aq)$$

Although its formula suggests that it should be a triprotic acid, H_3PO_3 is in fact diprotic because one of the H atoms is attached directly to the P atom and the P–H bond is nonpolar (Section 11.10).

When phosphorus burns in an ample supply of air, it forms phosphorus(V) oxide, P_4O_{10} (**14**). This white solid reacts so vigorously with water that it is widely used in the laboratory as a drying agent. Phosphorus(V) oxide is the anhydride of phosphoric acid, H_3PO_4 (**15**):

$$P_4O_{10}(s) + 6\,H_2O(l) \longrightarrow 4\,H_3PO_4(aq)$$



15 Phosphoric acid, H_3PO_4

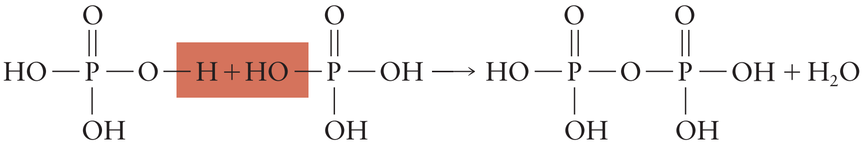
Phosphoric acid is used primarily for the production of fertilizers, in processed food to increase acidity, and in detergents. Many soft drinks owe their tart taste to the presence of low concentrations of phosphoric acid. Pure phosphoric acid, H_3PO_4, is a colorless

solid with a melting point of 42°C; but in the laboratory, it is normally a syrupy liquid on account of the water that it has absorbed. In fact, phosphoric acid is usually purchased as 85% H_3PO_4. Its high viscosity can be traced to extensive hydrogen bonding. Although phosphorus has a high oxidation number (+5), the acid shows appreciable oxidizing power only at temperatures above about 350°C; it may be used where nitric acid and sulfuric acid would be too strongly oxidizing.

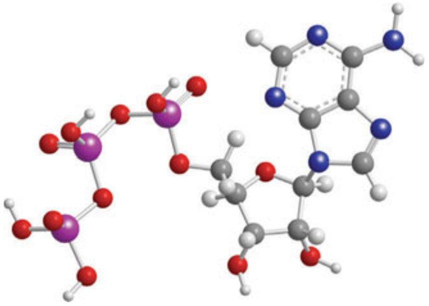
Phosphoric acid is the parent of the phosphates, which are of great commercial importance. Phosphate rock is mined in huge quantities in Florida and Morocco. After being crushed, it is treated with sulfuric acid to give a mixture of sulfates and phosphates called superphosphate, a major fertilizer:

$$Ca_3(PO_4)_2(s) + 2\,H_2SO_4(l) \longrightarrow 2\,CaSO_4(s) + Ca(H_2PO_4)_2(s)$$

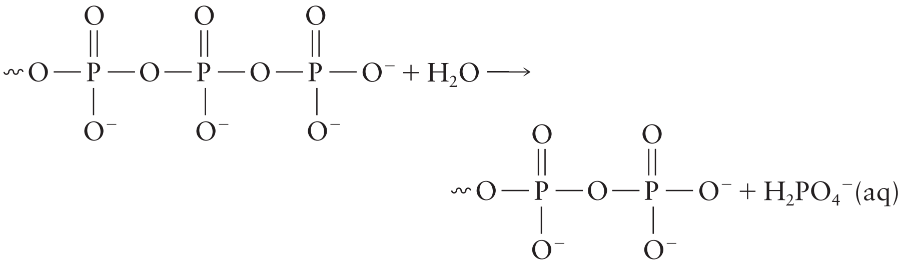
When phosphoric acid is heated, it undergoes a **condensation reaction,** a reaction in which two molecules combine together with the elimination of a small molecule, normally that of water:



The product, $H_4P_2O_7$, is pyrophosphoric acid. Further heating gives even more complicated products that have chains and rings of PO_4 groups. The products are called polyphosphoric acids. Polyphosphoric acids are far from being of only academic interest: they empower our actions and thoughts. The most important polyphosphate is adenosine triphosphate, ATP (**16**), which is found in every living cell. The triphosphate part of this molecule is a chain of three phosphate groups that are converted into adenosine diphosphate, ADP, in the body:



16 Adenosine triphosphate, ATP



(where the wiggly line indicates the rest of the molecule). Some energy is required to break the O—H bond in water and the relatively weak O—P bond in ATP, but more energy is released when the new O—H and O—P bonds form in the product ($\Delta G° = -30$ kJ at pH = 7). This energy is used to power energy-demanding processes in cells.

The oxides of phosphorus have structures based on the tetrahedral PO_4 unit; P_4O_6 and P_4O_{10} are the anhydrides of phosphorous acid and phosphoric acid, respectively. Polyphosphates are extended structures used (as ATP) by living cells to store and transfer energy.

Self-Test 15.13A How does (a) the acidity of a nitrogen oxoacid and (b) its strength as an oxidizing agent change as the oxidation number of N increases from +1 to +5?

[***Answer:*** (a) Increases; (b) increases]

Self-Test 15.13B What is the molarity of phosphoric acid in 85% (by mass) $H_3PO_4(aq)$, which has a density of 1.7 $g \cdot mL^{-1}$?

GROUP 16/VI: THE OXYGEN FAMILY

Elements become increasingly nonmetallic toward the right-hand side of the periodic table; by Group 16/VI, even polonium, at the foot of the group, is best regarded as a metalloid (Table 15.9). Here, on the far right of the periodic table, the electron configurations are only a few electrons short of a closed-shell, noble-gas configuration, and

TABLE 15.9 **The Group 16/VI Elements**

‡Radioactive.

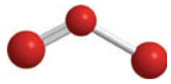
the effective nuclear charge is high. As a result, when the elements in Group 16/VI form compounds with other nonmetals, they do so by sharing electrons to form covalent bonds. The atoms have the valence electron configuration ns^2np^4, and so they need only two more electrons to complete their valence shells. The members of the group are collectively called the **chalcogens.**

15.19 The Group 16/VI Elements

Oxygen is the most abundant element in the Earth's crust, and the free element accounts for 23% of the mass of the atmosphere. Oxygen is much more reactive than nitrogen, the other major component of our atmosphere. The combustion of all living organisms in oxygen is thermodynamically spontaneous; however, we do not burst into flame at normal temperatures, because combustion has a high activation energy.

Recall Section 3.10, where we saw that in O_2 two unpaired electrons occupy two antibonding π-orbitals of the same energy.

Oxygen is a colorless, tasteless, odorless gas of O_2 molecules; the gas condenses to a pale-blue liquid at −183°C (Fig. 15.38). Although O_2 has an even number of electrons, two of them are unpaired, making the molecule paramagnetic; in other words, O_2 behaves like a tiny magnet and is attracted into a magnetic field. More than 2×10^{10} kg of liquid oxygen is produced each year in the United States (about 80 kg per inhabitant) by fractional distillation of liquid air. The biggest consumer of oxygen is the steel industry, which needs about 1 t of oxygen (1 t = 10^3 kg) to produce 1 t of steel. In steelmaking, oxygen is blown into molten iron to oxidize any impurities, particularly carbon (see Section 6.3). Elemental oxygen is also used for welding (to create a very hot flame in oxyacetylene torches) and in medicine. Physicians administer oxygen to relieve strain on the heart and lungs and as a stimulant.



17 Ozone, O_3

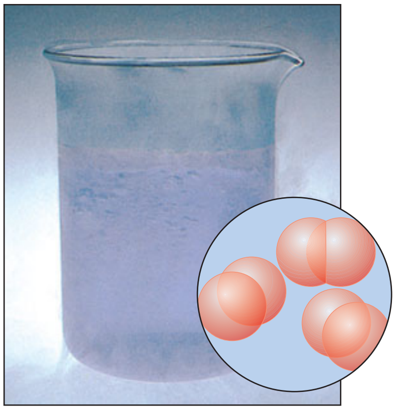


FIGURE 15.38 Liquid oxygen is pale blue. (The gas itself is colorless.) The inset shows that the gas consists of diatomic molecules known formally as dioxygen.

An allotrope of oxygen, ozone, O_3 (**17**), is formed in the stratosphere by the effect of solar radiation on O_2 molecules. Its total abundance in the atmosphere is equivalent to a layer that, at the ordinary conditions of 25°C and 1 bar, would cover the Earth to a thickness of only 3 mm, yet its presence in the stratosphere is vital to the maintenance of life on Earth (see Box 14.3). Ozone can be made in the laboratory by passing an electric discharge through oxygen. It is a blue gas that condenses at −112°C to an explosive blue liquid that looks like ink (Fig. 15.39). Its pungent smell can often be detected near electrical equipment and after lightning. Ozone is also present in smog, where it is produced by the reaction of oxygen molecules with oxygen atoms:

$$O + O_2 \longrightarrow O_3$$

The oxygen atoms are produced by the photochemical decomposition of NO_2, which is generated from emission products of automobile engines (Section 15.17):

$$NO_2 \xrightarrow{\text{UV radiation}} NO + O$$

Electronegativities decrease down Group 16 (Fig. 15.40), and atomic and ionic radii increase (Fig. 15.41). The differences between oxygen and sulfur are similar to those

FIGURE 15.39 Ozone is a blue gas that condenses to a dark-blue, highly unstable liquid. The inset shows that the gas consists of triatomic molecules.

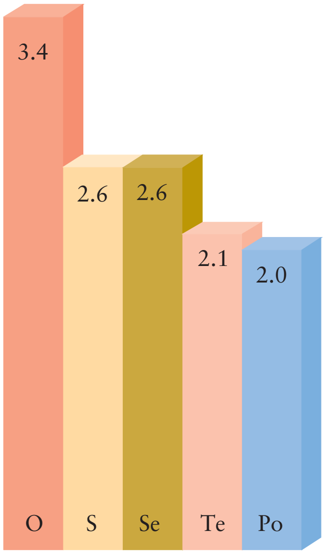

FIGURE 15.40 The electronegativities of the Group 16/VI elements decrease down the group.

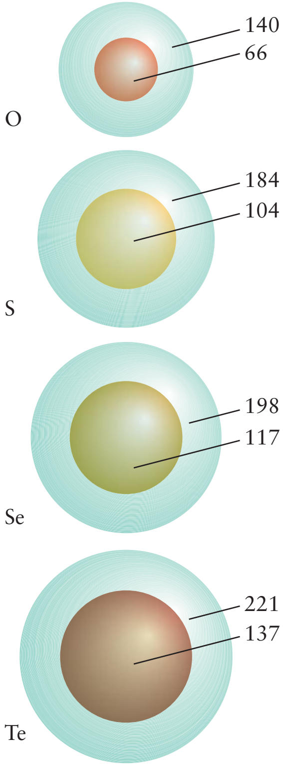

FIGURE 15.41 The atomic and ionic radii of the Group 16/VI elements increase steadily down the group. The values shown are in picometers, and each anion (shown green) is substantially larger than its neutral parent atom.

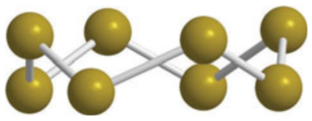
between nitrogen and phosphorus, and for similar reasons: sulfur has atoms that are 58% larger than those of oxygen, and it has a lower first ionization energy and electronegativity. The bonds that sulfur forms to hydrogen are much less polar than the bonds between oxygen and hydrogen. Consequently, S—H bonds do not take part in hydrogen bonding; as a result, H_2S is a gas, whereas H_2O is a liquid, despite the smaller number of electrons and hence weaker London forces. Sulfur also has weaker tendencies to form multiple bonds, tending to form additional single bonds to as many as six other atoms and using its d-orbitals to do so.

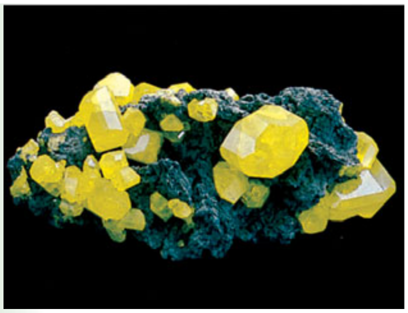
Sulfur has a striking ability to **catenate,** or form chains of atoms. Oxygen's ability to form chains is very limited, with H_2O_2, O_3, the anions O_2^-, O_2^{2-}, and O_3^-, and other peroxides the only examples. Sulfur's ability is much more pronounced. It appears, for instance, in the existence of S_8 rings, their fragments, and the long strands of "plastic sulfur" that form when sulfur is heated to about 200°C and suddenly cooled. The —S—S— links that connect different parts of the chains of amino acids in proteins are another example of catenation. These "disulfide links" contribute to the shapes of proteins, including the keratin of our hair; thus, sulfur helps to keep us alive and, perhaps, curly haired (see Section 19.13).

Sulfur is widely distributed as sulfide ores, which include *galena*, PbS; *cinnabar*, HgS; *iron pyrite*, FeS_2; and *sphalerite*, ZnS (Fig. 15.42). Because these ores are so common, sulfur is a by-product of the extraction of a number of metals, especially copper. Sulfur is also found as deposits of the native element (called brimstone), which are formed by bacterial action on H_2S. The low melting point of sulfur (115°C) is utilized in the **Frasch process,** in which superheated water is used to melt solid sulfur underground and compressed air pushes the resulting slurry to the surface. Sulfur is also commonly found in petroleum, and extracting it chemically has been made inexpensive and safe by the use of heterogeneous catalysts, particularly zeolites (see Section 14.15). One method

FIGURE 15.42 A collection of sulfide ores. From left to right: galena, PbS; cinnabar, HgS; pyrite, FeS_2; sphalerite, ZnS. Pyrite has a lustrous golden color and has frequently been mistaken for gold; hence, it is also known as fool's gold. Gold and fool's gold are readily distinguished by their densities.



18 Sulfur, S_8



(a)

(b)

FIGURE 15.43 One of the two most common forms of sulfur is the blocklike rhombic form (a). It differs from the needlelike monoclinic sulfur (b) in the manner in which the S_8 rings are stacked together.

Lab Video 15.43

FIGURE 15.44 Two of the Group 16/VI elements: selenium, which is a nonmetal, on the left and tellurium, a metalloid, on the right.

used to remove sulfur in the form of H_2S from petroleum and natural gas is the **Claus process,** in which some of the H_2S is first oxidized to sulfur dioxide:

$$2\,H_2S(g) + 3\,O_2(g) \longrightarrow 2\,SO_2(g) + 2\,H_2O(l)$$

The SO_2 is then used to oxidize the remainder of the hydrogen sulfide:

$$2\,H_2S(g) + SO_2(g) \xrightarrow{300°C,\ Al_2O_3} 3\,S(s) + 2\,H_2O(l)$$

Sulfur is of major industrial importance. Most of the sulfur that is produced is used to make sulfuric acid, but an appreciable amount is used to vulcanize rubber (Sec-tion 19.12).

Elemental sulfur is a yellow, tasteless, almost odorless, insoluble, nonmetallic molecular solid of crownlike S_8 rings (**18**). The two common crystal forms of sulfur are monoclinic sulfur and rhombic sulfur (recall the sulfur phase diagram in Fig. 9.8). The more stable form under normal conditions is rhombic sulfur, which forms beautiful yellow crystals (Fig. 15.43). At low temperatures, sulfur vapor consists mainly of S_8 molecules. At temperatures above 720°C, the vapor has a blue tint from the S_2 molecules that form. The latter are paramagnetic, like O_2.

Selenium and tellurium occur in sulfide ores; they are also recovered from the anode sludge formed during the electrolytic refining of copper (see Section 16.4). Both elements have several allotropes, the most stable consisting of long zigzag chains of atoms. Although these allotropes look like silver-white metals, they are poor electrical conductors (Fig. 15.44). The conductivity of selenium is increased by exposure to light, and so it is used in solar cells, photoelectric devices, and photocopying machines. Selenium also occurs as a deep-red solid consisting of Se_8 molecules.

Polonium is a radioactive, low-melting metalloid. It is a useful source of α particles (helium-4 nuclei; they are described in more detail in Section 15.24) and is used in antistatic devices in textile mills: the α particles reduce static by counteracting the negative charges that tend to build up on the fast-moving fabric.

Metallic character increases down Group 16/VI as electronegativity decreases. Oxygen and sulfur occur naturally in the elemental state; sulfur forms chains and rings with itself, but oxygen does not.

15.20 Compounds with Hydrogen

By far the most important compound of oxygen and hydrogen is water, H_2O. Municipal water supplies normally undergo several stages of purification (Fig. 15.45). Raw water is aerated by bubbling air through it to remove foul-smelling dissolved gases such as H_2S, to oxidize some organic compounds to CO_2, and to add oxygen. Adding slaked lime, $Ca(OH)_2$, reduces acidity, precipitates Mg^{2+}, Fe^{3+}, Cu^{2+}, and other metal ions as hydroxides, and softens hard water (see Sections 9.12 and 15.8). After the lime is added, the water is pumped into a primary settling basin. Because the precipitates tend to form as a colloid (a very fine powder that remains suspended in the water, Section 9.21), either $Fe_2(SO_4)_3$ or alum (specifically, $Al_2(SO_4)_3{\cdot}18H_2O$) is added to coagulate and flocculate the precipitate so that it can be filtered. **Coagulation** is the irreversible aggregation of small particles into larger particles; **flocculation** is the reversible, loose aggregation of somewhat larger particles to form a fluffy gel. At this point the water is basic and carbon dioxide is often added to lower the pH, which promotes precipitation of the aluminum as $Al(OH)_3$ so that it can be removed by filtration (Section 15.10).

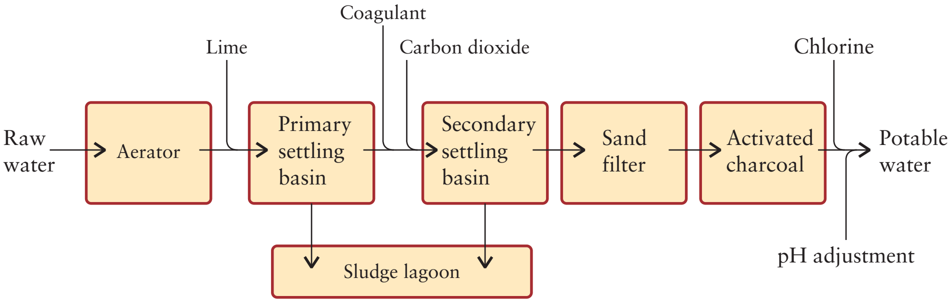


FIGURE 15.45 Typical steps in the purification of drinking water.

As the precipitate settles slowly in a secondary basin, it adsorbs any remaining suspended $CaCO_3$, bacteria, and other particles, such as dirt and algae. Precipitates from the primary and secondary basins are combined in a sludge lagoon for disposal. The water is then passed through a sand filter to remove any remaining suspended particles.

The pH of the water is checked again and made slightly basic to reduce acid corrosion of the pipes. At this point, a disinfectant, usually chlorine, is added. In the United States, the chlorine level is required to be greater than 1 g of Cl_2 per 1000 kg (1 ppm by mass) of water at the point of consumption. In water, chlorine forms hypochlorous acid, which is highly toxic to bacteria:

$$Cl_2(g) + 2\,H_2O(l) \longrightarrow H_3O^+(aq) + Cl^-(aq) + HClO(aq)$$

Additional water purification steps, such as reverse osmosis may be required (Section 9.17), depending on the source and condition of the water.

Because water is a common solvent we might think of it merely as a passive medium in which chemical reactions take place. However, water is a reactive compound, and an alien raised in a nonaqueous environment might consider it aggressively corrosive and be surprised at our survival. For instance, water is an oxidizing agent:

$$2\,H_2O(l) + 2\,e^- \longrightarrow 2\,OH^-(aq) + H_2(g) \qquad E = -0.42\text{ V at pH} = 7$$

One example is its reaction with the alkali metals, as in

$$2\,Na(s) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g)$$

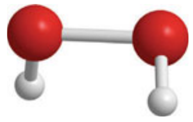
However, unless the other reactant is a strong reducing agent, water acts as an oxidizing agent only at high temperatures, as in the re-forming reaction (Section 15.3).

Water is a very mild reducing agent:

$$4\,H^+(aq) + O_2(g) + 4\,e^- \longrightarrow 2\,H_2O(l) \qquad E = +0.82\text{ V at pH} = 7$$

However, few substances besides fluorine are strong enough oxidizing agents to accept the electrons released in the reverse of this half-reaction.

Water is also a Lewis base, because an H_2O molecule can donate one of its lone pairs to a Lewis acid and form complexes such as $Fe(H_2O)_6^{3+}$. Water's ability to act as a Lewis base is also the origin of its ability to hydrolyze substances. The reaction between water and phosphorus pentachloride mentioned in Section 15.18 is an example.



19 Hydrogen peroxide, H_2O_2

Hydrogen peroxide, H_2O_2 (**19**), is a very pale blue liquid that is appreciably denser than water (1.44 g·mL^{-1} at 25°C) but similar in other physical properties: its melting point is −0.4°C, and its boiling point is 152°C. Chemically, though, hydrogen peroxide and water differ greatly. The presence of the second oxygen atom makes H_2O_2 a very weak acid ($pK_{a1} = 11.75$). Hydrogen peroxide is a stronger oxidizing agent than water. For example, H_2O_2 oxidizes Fe^{2+} and Mn^{2+} in acidic and basic solutions. It can also act as a reducing agent in the presence of more powerful oxidizing agents such as permanganate ions and chlorine (usually in basic solution).

Hydrogen peroxide is normally sold for industrial use as a 30% by mass aqueous solution. When used as a hair bleach (as a 6% solution), it acts by oxidizing the pigments in the hair. A 3% H_2O_2 aqueous solution is used as a mild antiseptic in the home. Contact with blood catalyzes its disproportionation into water and oxygen gas, which cleanses the wound:

$$2\,H_2O_2(aq) \longrightarrow 2\,H_2O(l) + O_2(g)$$

Because it oxidizes unpleasant effluents without producing any harmful by-products, H_2O_2 is also increasingly used as an oxidizing agent to control pollution.

Self-Test 15.14A From the Lewis structures of the following molecules, determine which are paramagnetic and explain how you decided: (a) N_2O_3; (b) NO; (c) N_2O.

[***Answer:*** (b) NO is paramagnetic, because it has an unpaired electron.]

Self-Test 15.14B Write the half-reactions and the overall reaction for the oxidation of water by F_2 in acidic solution. Determine the standard potential and $\Delta G°$ for the reaction.

FIGURE 15.46 The blue stones in this ancient Egyptian ornament are lapis lazuli. This semiprecious stone is an aluminosilicate colored by S_2^- and S_3^- impurities. The blue color is due to S_3^- and the hint of green to S_2^-.

Except for water, all the Group 16/VI binary compounds with hydrogen (the compounds H_2E, where E is a Group 16/VI element) are toxic gases with offensive odors. They are insidious poisons because they paralyze the olfactory nerve and, soon after exposure, the victim cannot smell them. Rotten eggs smell of hydrogen sulfide, H_2S, because egg proteins contain sulfur and give off the gas when they decompose. Another sign of the formation of sulfides in eggs is the pale green discoloration sometimes seen in hard-boiled eggs where the white meets the yolk: this color is a deposit of iron(II) sulfide. Hydrogen sulfide, H_2S, is prepared either by protonation of the sulfide ion, a Brønsted base, in a reaction such as

$$FeS(s) + 2\,HCl(aq) \longrightarrow FeCl_2(aq) + H_2S(g)$$

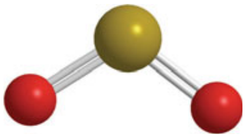
or by direct reaction of the elements at 600°C.

Hydrogen sulfide dissolves in water to give a solution of hydrosulfuric acid that, as a result of its oxidation by dissolved air, slowly becomes cloudy as S_8 molecules form and then coagulate. Hydrosulfuric acid is a weak diprotic acid and the parent acid of the hydrogen sulfides (which contain the HS^- ion) and the sulfides (which contain the S^{2-} ion). The sulfides of the s-block elements are moderately soluble, whereas the sulfides of the heavy p- and d-block metals are generally very insoluble.

The sulfur analog of hydrogen peroxide also exists and is an example of a *polysulfane*, a catenated molecular compound of composition $HS{-}S_n{-}SH$, where n can take on values from 0 through 6. The polysulfide ions obtained from the polysulfanes include two ions found in lapis lazuli (Fig. 15.46).

Water can act as a Lewis base, an oxidizing agent, and a weak reducing agent; hydrogen peroxide is a stronger oxidizing agent than water. Hydrogen sulfide is a weak acid; the polysulfanes exhibit the ability of sulfur to catenate.

15.21 Sulfur Oxides and Oxoacids



20 Sulfur dioxide, SO_2

Sulfur forms several oxides that in atmospheric chemistry are referred to collectively as SO_x (read “sox”). The most important oxides and oxoacids of sulfur are the dioxide and trioxide and the corresponding sulfurous and sulfuric acids. Sulfur burns in air to form sulfur dioxide, SO_2 (**20**), a colorless, choking, poisonous gas (recall Fig. C.1). About 7×10^{10} kg of sulfur dioxide is produced annually from the decomposition of vegetation and from volcanic emissions. In addition, approximately 1×10^{11} kg of naturally occurring hydrogen sulfide is oxidized each year to the dioxide by atmospheric oxygen:

$$2\,H_2S(g) + 3\,O_2(g) \longrightarrow 2\,SO_2(g) + 2\,H_2O(g)$$

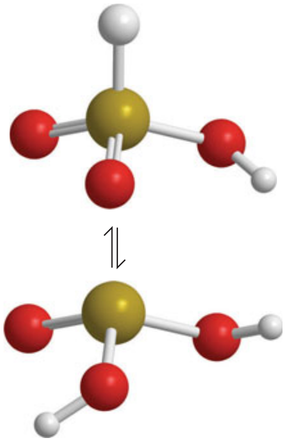
Industry and transport contribute another 1.5×10^{11} kg of the dioxide, of which about 70% comes from oil and coal combustion—mainly in electricity-generating plants. Because, like many other countries, the United States and Canada have increased restrictions on emissions of sulfur oxides, emissions of SO_2 into the atmosphere in North America fell by about 54% between 1980 and 2007. The more stringent regulations that came into effect in the twenty-first century should allow for a further 50% reduction (see Box 11.1).

Sulfur dioxide is the anhydride of sulfurous acid, H_2SO_3, which is the parent acid of the hydrogen sulfites (or bisulfites) and the sulfites:

$$SO_2(g) + H_2O(l) \longrightarrow H_2SO_3(aq)$$

(a)

(b)



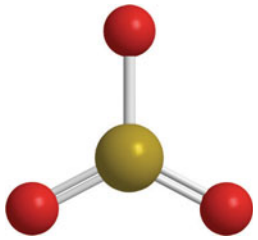
21 Sulfurous acid, H_2SO_3

Sulfurous acid is an equilibrium mixture of two molecules (**21a** and **21b**); in (a) it resembles phosphorous acid, with one of the H atoms attached directly to the S atom. These molecules are also in equilibrium with molecules of SO_2, each of which is surrounded by a cage of water molecules. The evidence for this equilibrium is that crystals of composition $SO_2{\cdot}xH_2O$, with x about 7, are obtained when the solution is cooled. Such substances, in which a molecule occupies a cage formed by other molecules, are called **clathrates.** Methane, carbon dioxide, and the noble gases also form clathrates with water.

Sulfur dioxide is easily liquified under pressure and can therefore be used as a refrigerant. It is also a preservative for dried fruit and a bleach for textiles and flour, but its most important use is in the production of sulfuric acid.

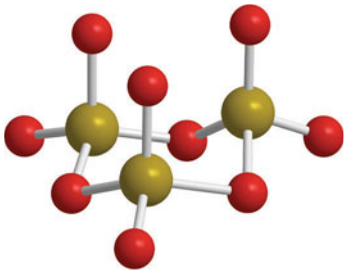
The oxidation number of sulfur in sulfur dioxide and the sulfites is +4, an intermediate value in sulfur's range from −2 to +6. Hence, these compounds can act as either oxidizing agents or reducing agents. By far the most important reaction of sulfur dioxide is its slow oxidation to sulfur trioxide, SO_3 (**22**), in which sulfur has the oxidation number +6:

$$2\,SO_2(g) + O_2(g) \longrightarrow 2\,SO_3(g)$$



22 Sulfur trioxide, SO_3

At normal temperatures, sulfur trioxide is a volatile liquid (its boiling point is 45°C), composed of trigonal planar SO_3 molecules. In the solid and to some extent in the liquid, these molecules form trimers (unions of three molecules) of composition S_3O_9 (**23**) as well as larger clusters.



23 Sulfur trioxide trimer, S_3O_9

Sulfuric acid, H_2SO_4, is produced commercially in the *contact process*, in which sulfur is first burned in oxygen and the SO_2 produced is oxidized to SO_3 over a V_2O_5 catalyst:

$$S(s) + O_2(g) \xrightarrow{1000°C} SO_2(g)$$

$$2\,SO_2(g) + O_2(g) \xrightarrow{500°C,\ V_2O_5} 2\,SO_3(g)$$

Because sulfur trioxide forms a corrosive acid mist with water vapor, it is absorbed instead in 98% concentrated sulfuric acid to give the dense, oily liquid called *oleum:*

$$SO_3(g) + H_2SO_4(l) \longrightarrow H_2S_2O_7(l)$$

Oleum is then converted into the acid by reaction with water:

$$H_2S_2O_7(l) + H_2O(l) \longrightarrow 2\,H_2SO_4(l)$$

Sulfuric acid is the inorganic chemical manufactured in the greatest amount worldwide, the annual production in the United States alone being more than 3×10^{10} kg. The low cost of sulfuric acid leads to its widespread use in industry, particularly for the production of fertilizers, petrochemicals, dyestuffs, and detergents. About two-thirds is used in the manufacture of phosphate and ammonium sulfate fertilizers (see Section 15.18).

Sulfuric acid is a colorless, corrosive, oily liquid that boils (and decomposes) at about 300°C. It has three chemically important properties: it is a strong Brønsted acid, a dehydrating agent, and an oxidizing agent (Fig. 15.47). Sulfuric acid is a strong acid in the sense that its first deprotonation is almost complete at normal concentrations in water. Its conjugate base HSO_4^- is a weak acid, with $pK_a = 1.92$ (Section 11.14). Sulfuric acid forms strong hydrogen bonds with water. The energy released when these bonds form can cause the mixture to boil violently. Sulfuric acid should always be diluted slowly and with great care, making sure to add the acid to the water, instead of the reverse, to avoid splashing concentrated acid.

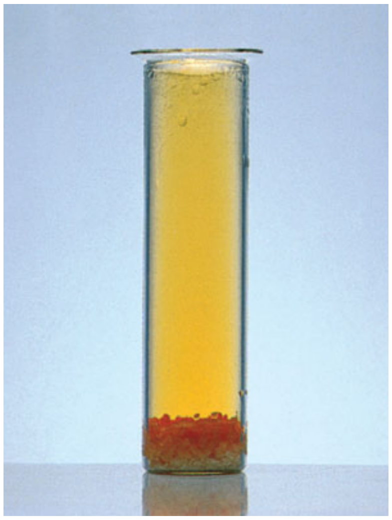


FIGURE 15.47 Sulfuric acid is an oxidizing agent. When some concentrated acid is poured on solid sodium bromide, NaBr, the bromide ions are oxidized to elemental bromine, which colors the mixture red-brown.

The powerful dehydrating ability of sulfuric acid is seen when a little concentrated acid is poured on sucrose, $C_{12}H_{22}O_{11}$. A black, frothy mass of carbon forms as a result of the extraction of H_2O (Fig. 15.48):

$$C_{12}H_{22}O_{11}(s) \longrightarrow 12\,C(s) + 11\,H_2O(l)$$

(a) (b) (c)

FIGURE 15.48 Sulfuric acid is a dehydrating agent. When concentrated sulfuric acid is poured on to sucrose (a), the sucrose, a carbohydrate, is dehydrated (b), leaving a frothy black mass of carbon (c).

‡Radioactive.

The froth is caused by the generation of the gases CO and CO_2 in side reactions.

Sulfur dioxide is the anhydride of sulfurous acid, and sulfur trioxide is the anhydride of sulfuric acid. Sulfuric acid is a strong acid, a dehydrating agent, and an oxidizing agent.

Self-Test 15.15A What is the oxidation number of sulfur in (a) the dithionate ion, $S_2O_6^{2-}$; (b) the thiosulfate ion, $S_2O_3^{2-}$?

[***Answer:*** (a) +5; (b) +2]

Self-Test 15.15B What is the oxidation number of sulfur in (a) S_2Cl_2; (b) oleum, $H_2S_2O_7$?

GROUP 17/VII: THE HALOGENS

The unique properties of the halogens (Table 15.10), the members of Group 17/VII, can be traced to their valence configuration, ns^2np^5, which needs only one more electron to reach a closed-shell configuration. To complete the octet of valence electrons, in the elemental state all halogen atoms combine to form diatomic molecules, such as F_2 and I_2. With the exception of fluorine, the halogens can also lose valence electrons and their oxidation states can range from −1 to +7. The elements form a family showing the smooth trends in physical properties that we would expect when London forces between molecules are the dominant intermolecular force. Because electronegativity decreases down the group (Fig. 15.49) and atomic and ionic radii increase smoothly down the group (Fig. 15.50), chemical properties show smooth trends as well, with the exception of some properties of fluorine.

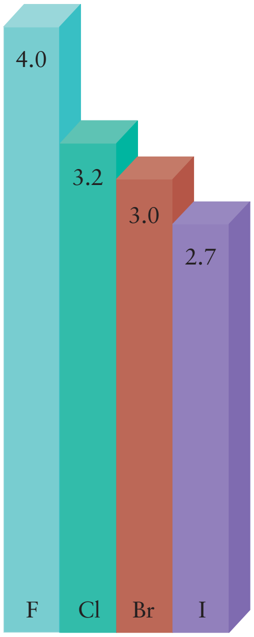

FIGURE 15.49 The electronegativities of the halogens decrease steadily down the group.

15.22 The Group 17/VII Elements

Fluorine, the first element of the group, is the halogen of greatest abundance in the Earth's crust. It occurs widely in many minerals, including *fluorspar*, CaF_2; *cryolite*, Na_3AlF_6; and the *fluorapatites*, $Ca_5(PO_4)_3F$. Because fluorine is the most strongly oxidizing element ($E° = +2.87$ V), it cannot be obtained from its compounds by oxidation with another element. Fluorine is produced by electrolyzing an anhydrous molten mixture of potassium fluoride and hydrogen fluoride at about 75°C with a carbon anode.

Fluorine is a reactive, almost colorless gas of F_2 molecules. Most of the fluorine produced by industry is used to make the volatile solid UF_6 used for processing nuclear fuel (Section 17.12). Much of the rest is used in the production of SF_6 for electrical equipment.

Fluorine has a number of peculiarities that stem from its high electronegativity, small size, and lack of available d-orbitals. It is the most electronegative element of all and has an oxidation number of −1 in all its compounds. Its high electronegativity and small size allow it to oxidize other elements to their highest oxidation numbers. The small size helps in this, because it allows several F atoms to pack around a central atom, as in IF_7.

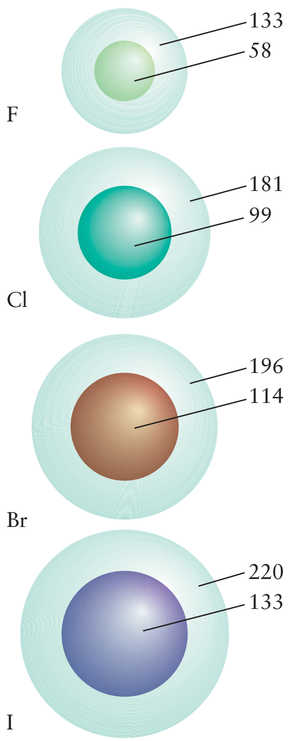

FIGURE 15.50 The atomic and ionic radii of the halogens increase steadily down the group as electrons occupy outer shells of the atoms. The values shown are in picometers. In all cases, the radii of the anions (represented by the green spheres) are larger than the atomic radii.

Because the fluoride ion is so small, the lattice enthalpies of its ionic compounds tend to be high (see Table 7.6). As a result, fluorides are less soluble than other halides. This difference in solubility is one of the reasons why the oceans are salty with chlorides rather than fluorides, even though fluorine is more abundant than chlorine in the Earth's crust. Chlorides are more readily dissolved and washed out to sea. There are some exceptions to this trend in solubilities, including AgF, which is soluble; the other silver halides are insoluble. The exception arises because the covalent character of the silver halides increases from AgCl to AgI as the anion becomes larger and more polarizable. Silver fluoride, which contains the small and almost unpolarizable fluoride ion, is freely soluble in water because it is predominantly ionic.

Chlorine is one of the chemicals manufactured in the greatest amount worldwide. It is obtained from sodium chloride by electrolysis of molten rock salt or brine (recall Sections 13.13 and 15.6). It is a pale yellow-green gas of Cl_2 molecules that condenses at $-34°C$. It reacts directly with nearly all the elements (notable exceptions are carbon, nitrogen, oxygen, and the noble gases). It is a strong oxidizing agent and oxidizes metals to high oxidation states; for example, anhydrous iron(III) chloride, not iron(II) chloride, is formed when chlorine reacts with iron (Fig. 15.51):

$$2\,Fe(s) + 3\,Cl_2(g) \longrightarrow 2\,FeCl_3(s)$$

Chlorine is used in a number of industrial processes, including the manufacture of plastics, solvents, and pesticides. It is used as a bleach in the paper and textile industries and as a disinfectant in water treatment (Section 15.20).

Chlorine is also used to produce bromine from brine wells through the oxidation of Br^- ions (see Fig. K.2):

$$2\,Br^-(aq) + Cl_2(g) \longrightarrow Br_2(l) + 2\,Cl^-(aq)$$

Air is bubbled through the solution to vaporize the bromine and drive it out.

Bromine is a corrosive, red-brown fuming liquid of Br_2 molecules that has a penetrating odor. Bromine is used widely in synthetic organic chemistry because of the ease with which it can be added to and removed from organic chemicals that are being used to carry out complicated syntheses. Organic bromides are incorporated into textiles as fire retardants and are used as pesticides; inorganic bromides, particularly silver bromide, are used in photographic emulsions.

FIGURE 15.51 Iron reacts vigorously and exothermically with chlorine to form anhydrous iron(III) chloride.

Iodine occurs as iodide ions in brines and as an impurity in Chile saltpeter. It was once obtained from seaweed, which contains high concentrations accumulated from seawater: 2000 kg of seaweed produce about 1 kg of iodine. The best modern source is the brine from oil wells; the oil itself was produced by the decay of marine organisms that had accumulated the iodine while they were alive. Elemental iodine is produced by oxidation with chlorine:

$$Cl_2(g) + 2\,I^-(aq) \longrightarrow I_2(aq) + 2\,Cl^-(aq) \qquad \Delta G° = -54.54\ kJ$$

The blue-black lustrous solid sublimes easily and forms a purple vapor.

When iodine dissolves in organic solvents, it produces solutions having a variety of colors. These colors arise from the different interactions between the I_2 molecules and the solvent (Fig. 15.52). The element is only slightly soluble in water, unless I^- ions are present, in which case the soluble brown triiodide ion, I_3^-, is formed. Iodine itself has few direct uses; but dissolved in alcohol, it is familiar as a mild oxidizing antiseptic. Because it is an essential trace element for living systems but scarce in inland areas, iodides are added to table salt (sold as "iodized salt") in order to prevent an iodine deficiency.

Astatine is a radioactive element that occurs in nature in uranium and thorium ores, but only to a minute extent. Samples are made by bombarding bismuth with α particles in a cyclotron, which accelerates the particles to a very high speed. Astatine

FIGURE 15.52 Solutions of iodine in a variety of solvents. From left to right, the first three solvents are tetrachloromethane (carbon tetrachloride), water, and potassium iodide solution, in which the brown I_3^- ion forms. In the solution on the far right, some starch has been added to a solution of I_3^-. The intense blue color that results has led to the use of starch as an indicator for the presence of iodine.

isotopes do not exist long enough for its properties to be studied, but it is thought from spectroscopic measurements to have properties similar to those of iodine.

Self-Test 15.16A (a) State the oxidation number of Cl in Cl_2O_7 and (b) write the chemical equation for its reaction with water.

[***Answer:*** (a) +7; (b) $Cl_2O_7(aq) + H_2O(l) \longrightarrow 2\ HClO_4(aq)$]

Self-Test 15.16B Explain the trends in the melting points and boiling points of the halogens.

The halogens show smooth trends in chemical properties down the group; fluorine has some anomalous properties, such as its strength as an oxidizing agent and the lower solubilities of most fluorides.

15.23 Compounds of the Halogens

The halogens form compounds among themselves. These **interhalogens** have the formulas XX′, XX'_3, XX'_5, and XX'_7, where X is the heavier (and larger) of the two halogens. Only some of the possible combinations have been synthesized (Table 15.11). They are all prepared by direct reaction of the two halogens, the product formed being determined by the proportions of reactants used. For example,

$$Cl_2(g) + 3\ F_2(g) \longrightarrow 2\ ClF_3(g)$$
$$Cl_2(g) + 5\ F_2(g) \longrightarrow 2\ ClF_5(g)$$

The physical properties of the interhalogens are intermediate between those of their parent halogens. Trends in the chemistry of the interhalogen fluorides can be related to the decrease in bond dissociation energy as the central halogen atom becomes heavier. The fluorides of the heavier halogens are all very reactive: bromine trifluoride gas is so reactive that even asbestos burns in it.

The hydrogen halides, HX, can be prepared by the direct reaction of the elements:

$$H_2(g) + X_2(g) \longrightarrow 2\ HX(g)$$

Fluorine reacts explosively by a radical chain reaction as soon as the gases are mixed. A mixture of hydrogen and chlorine also explodes when exposed to light. Bromine and iodine react with hydrogen much more slowly. A less hazardous laboratory source of the hydrogen halides is the action of a nonvolatile acid on a metal halide, as in

$$CaF_2(s) + 2\ H_2SO_4(aq, conc) \longrightarrow Ca(HSO_4)_2(aq) + 2\ HF(g)$$

Because Br^- and I^- are oxidized by sulfuric acid, phosphoric acid is used in the preparation of HBr and HI:

$$KI(s) + H_3PO_4(aq) \xrightarrow{\Delta} KH_2PO_4(aq) + HI(g)$$

TABLE 15.11 Known Interhalogens

Interhalogen	Normal form*

(a) (b)

FIGURE 15.53 When a mixture of hydrofluoric acid and ammonium fluoride is swirled inside a glass vial (a), reaction with the silica in the glass frosts the surface of the cover glass as well as the walls of the vial (b).

Lab Video 15.53

All the hydrogen halides are colorless, pungent gases except hydrogen fluoride, which is a liquid at temperatures below 20°C. Its low volatility is a sign of extensive hydrogen bonding, and short zigzag chains of hydrogen-bonded molecules, up to about $(HF)_5$, survive to some extent in the vapor. All the hydrogen halides dissolve in water to give acidic solutions. Hydrofluoric acid has the distinctive property of attacking glass and silica (see Fig. 6.22). The interiors of lamp bulbs are frosted by the vapors from an aqueous solution of hydrofluoric acid and ammonium fluoride (Fig. 15.53).

Hydrogen fluoride is used to make fluorinated carbon compounds, such as Teflon (polytetrafluoroethylene) and the refrigerant R134a (CF_3CH_2F). Most fluoro-substituted hydrocarbons are relatively inert chemically: they are inert to oxidation by air, hot nitric acid, concentrated sulfuric acid, and other strong oxidizing agents. Consequently, Teflon is used to line chemical reactor vessels and to coat the surfaces of nonstick cookware. Because R134a does not contribute to global warming or the destruction of ozone in the stratosphere and is relatively unreactive and nontoxic, it is now the refrigerant most recommended for use in air conditioners in the United States.

The acid strengths and oxidizing abilities of the halogen oxoacids increase with the oxidation number of the halogen (see Section 11.10). The hypohalous acids, HXO (halogen oxidation number +1), are prepared by direct reaction of the halogen with water. For example, chlorine gas disproportionates in water to produce hypochlorous acid and hydrochloric acid:

$$\overset{0}{Cl_2}(g) + H_2O(aq) \longrightarrow H\overset{+1}{Cl}O(aq) + H\overset{-1}{Cl}(aq)$$

Hypohalite ions, XO^-, are formed when a halogen is added to the aqueous solution of a base. Sodium hypochlorite, NaClO, is produced from the electrolysis of brine when the electrolyte is rapidly stirred, and the chlorine gas produced at the anode reacts with the hydroxide ion generated at the cathode. The chlorine gas disproportionates to produce hypochlorite and chloride ions:

$$\overset{0}{Cl_2}(g) + 2\,OH^-(aq) \longrightarrow \overset{+1}{Cl}O^-(aq) + \overset{-1}{Cl^-}(aq) + H_2O(l)$$

Because hypochlorites oxidize organic material, they are used in liquid household bleaches and as disinfectants. Their action as oxidizing agents stems partly from the decomposition of hypochlorous acid in solution:

$$2\,HClO(aq) \longrightarrow 2\,H^+(aq) + 2\,Cl^-(aq) + O_2(g)$$

The oxygen either bubbles out of the solution or attacks oxidizable material. Calcium hypochlorite is the main component of bleach powders and is used for purifying the

water in home swimming pools. It is used for swimming pools in preference to sodium hypochlorite because the Ca^{2+} ions form insoluble calcium carbonate, which is removed by filtration; sodium would remain in solution and make the water too salty.

Chlorate ions, ClO_3^- (oxidation state +5), form when chlorine reacts with hot concentrated aqueous alkali:

$$3\,Cl_2(g) + 6\,OH^-(aq) \xrightarrow{\Delta} ClO_3^-(aq) + 5\,Cl^-(aq) + 3\,H_2O(l)$$

They decompose when heated, to an extent that depends on whether a catalyst is present:

$$4\,KClO_3(s) \xrightarrow{\Delta} 3\,KClO_4(s) + KCl(s)$$

$$2\,KClO_3(s) \xrightarrow{\Delta,\ MnO_2} 2\,KCl(s) + 3\,O_2(g)$$

The latter reaction is a convenient laboratory source of oxygen.

Chlorates are useful oxidizing agents. Potassium chlorate is used as an oxidant in fireworks and in matches. The heads of safety matches consist of a paste of potassium chlorate, antimony sulfide, and sulfur, with powdered glass to create friction when the match is struck; as mentioned in Section 15.15, the striking strip contains red phosphorus, which ignites the match head.

The principal use of sodium chlorate is as a source of chlorine dioxide, ClO_2. The chlorine in ClO_2 has oxidation number +4, and so the chlorate must be reduced to form it. Sulfur dioxide is a convenient reducing agent for this reaction:

$$2\,NaClO_3(aq) + SO_2(g) + H_2SO_4(aq, dilute) \longrightarrow 2\,NaHSO_4(aq) + 2\,ClO_2(g)$$

Chlorine dioxide has an odd number of electrons and is a paramagnetic yellow gas. Despite the environmental damage it creates, it is often used to bleach paper pulp, because it can oxidize the various pigments in the pulp without degrading the wood fibers.

The perchlorates, ClO_4^- (oxidation state +7), are prepared by electrolytic oxidation of aqueous chlorates:

$$ClO_3^-(aq) + H_2O(l) \longrightarrow ClO_4^-(aq) + 2\,H^+(aq) + 2\,e^-$$

Perchloric acid, $HClO_4$, is prepared by the action of concentrated hydrochloric acid on sodium perchlorate, followed by distillation. It is a colorless liquid and the strongest of all common acids. Because chlorine has its highest oxidation number, +7, in these compounds, they are powerful oxidizing agents; contact between perchloric acid and even a small amount of organic material can result in a dangerous explosion.

One spectacular example of the oxidizing ability of perchlorates is their use in the booster rockets of space shuttles. The solid propellant consists of aluminum powder (the fuel), ammonium perchlorate (the oxidizing agent as well as a fuel), and iron(III) oxide (the catalyst). These reactants are mixed into a liquid polymer, which sets to a solid inside the rocket shell. A variety of products can form when the mixture is ignited. One of the reactions is

$$3\,NH_4ClO_4(s) + 3\,Al(s) \xrightarrow{Fe_2O_3} Al_2O_3(s) + AlCl_3(s) + 6\,H_2O(g) + 3\,NO(g)$$

The solid products form the thick clouds of white powder emitted by the solid rocket boosters during liftoff (Fig. 15.54).

FIGURE 15.54 The white smoke emitted by the shuttle booster rockets consists of powdered aluminum oxide and aluminum chloride.

Self-Test 15.17A Which oxoacid of bromine is (a) the strongest acid? (b) the strongest oxidizing agent? Explain your answers.

[***Answer:*** For both (a) and (b), $HBrO_4$, because it has the most O atoms]

Self-Test 15.17B How does pH affect the oxidizing power of $HClO_3$?

The interhalogens have properties intermediate between those of the constituent halogens. Nonmetals form covalent halides; metals tend to form ionic halides. The oxoacids of chlorine are all oxidizing agents; both acidity and oxidizing strength of oxoacids increase as the oxidation number of the halogen increases.

TABLE 15.12 The Group 18/VIII Elements (the Noble Gases)

Valence configuration: ns^2np^6
Normal form: colorless monatomic gas

Z	Name	Symbol	Molar mass ($g \cdot mol^{-1}$)	Melting point (°C)	Boiling point (°C)
2	helium	He	4.00	—	−269 (4.2 K)

86	radon*	Rn	(222)	−71	−62

*Radioactive.

GROUP 18/VIII: THE NOBLE GASES

The elements in Group 18/VIII, the noble gases, get their group name from their very low reactivity (Table 15.12). Experiments on the gases and, later, recognition of their closed-shell electron configurations (ns^2np^6) prompted the belief that these elements were chemically inert. Indeed, no compounds of the noble gases were known until 1962. That year, the British chemist Neil Bartlett synthesized the first noble-gas compound, xenon hexafluoroplatinate, $XePtF_6$. Soon after, chemists at Argonne National Laboratory made xenon tetrafluoride, XeF_4, from a high-temperature mixture of xenon and fluorine.

15.24 The Group 18/VIII Elements

All the Group 18/VIII elements occur in the atmosphere as monatomic gases; together they make up about 1% of its mass. Argon is the third most abundant gas in the atmosphere after nitrogen and oxygen (discounting the variable amount of water vapor). All the noble gases except helium and radon are obtained by the fractional distillation of liquid air.

Helium, the second most abundant element in the universe after hydrogen, is rare on Earth because its atoms are so light that a large proportion of them reach high speeds and escape from the atmosphere; unlike hydrogen, they cannot be anchored to compounds. However, helium is found as a component of natural gases trapped under rock formations (notably in Texas), where it has collected as a result of the emission of α particles by radioactive elements. An α particle is a helium-4 nucleus ($^4He^{2+}$), and an atom of the element forms when the particle picks up two electrons from its surroundings.

Helium gas is twice as dense as hydrogen under the same conditions. Nevertheless, because its density is still very low and it is nonflammable, it is used to provide buoyancy in airships such as blimps. Helium is also used to dilute oxygen for use in hospitals and in deep-sea diving, to pressurize rocket fuels, as a coolant, and in helium–neon lasers. The element has the lowest boiling point of any substance (4.2 K), and it does not freeze to a solid at any temperature unless pressure is applied to hold the light, mobile atoms together. These properties and its chemical inertness make helium useful for **cryogenics**, the study of matter at very low temperatures, such as those used for the study of superconductivity (Section 6.14). Helium is the only substance known to have more than one liquid phase. Its phase diagram indicates the temperature and pressure ranges over which each phase is stable (Fig. 15.55). Below 2 K, liquid helium-II shows the remarkable property of **superfluidity,** the ability to flow without viscosity.

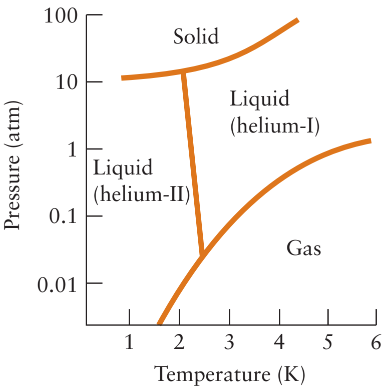

FIGURE 15.55 The phase diagram for helium-4 shows the two liquid phases of helium. Helium-II, the low-temperature liquid phase, is a superfluid.

Neon, which emits an orange-red glow when an electric current flows through it, is widely used in advertising signs and displays (Fig. 15.56). Argon is used to provide an inert atmosphere for welding (to prevent oxidation) and to fill some types of light bulbs, where it conducts heat away from the filament. Krypton gives an intense white light when an electric discharge is passed through it, and so it is used in airport runway lighting. Because krypton is produced by nuclear fission, its atmospheric abundance is one measure of

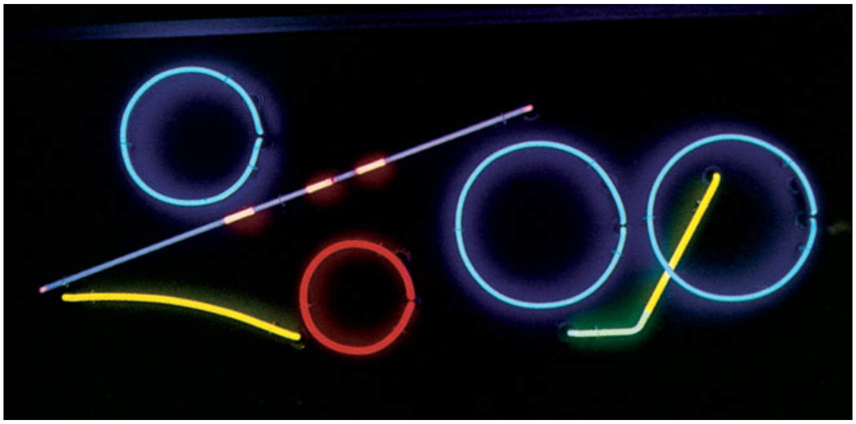

FIGURE 15.56 The colors of this fluorescent lighting art by Tom Anthony are due to emission from noble-gas atoms. Neon is responsible for the red light; when it is mixed with a little argon, the color becomes blue-green. The yellow color is achieved by coating the inside of the glass with phosphors that give off yellow light when excited.

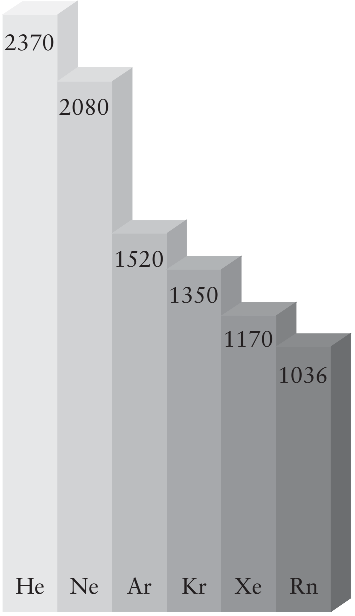

FIGURE 15.57 The ionization energies of the noble gases decrease steadily down the group. The values shown are in kilojoules per mole.

worldwide nuclear activity. Xenon is used in halogen lamps for automobile headlights and in high-speed photographic flash tubes; it is also being investigated as an anesthetic.

The radioactive gas radon seeps out of the ground as a product of radioactive decay processes deep in the Earth. There is now some concern that its accumulation in buildings and its nuclear decay products can lead to dangerously high levels of radiation.

The noble gases are all found naturally as unreactive monatomic gases. Helium has two liquid phases; the lower-temperature liquid phase exhibits superfluidity.

15.25 Compounds of the Noble Gases

The ionization energies of the noble gases are very high but decrease down the group (Fig. 15.57). Xenon's ionization energy is low enough for electrons to be lost to very electronegative elements. No compounds of helium, neon, and argon exist, except under very special conditions, such as the capture of atoms of He and Ne inside a buckminsterfullerene cage. Krypton forms only one known stable neutral molecule, KrF_2. In 1988, a compound with a Kr—N bond was reported, but it is stable only below −50°C. This leaves xenon as the noble gas with the richest chemistry. It forms several compounds with fluorine and oxygen, and compounds with Xe—N and Xe—C bonds have been reported, such as $(C_6F_5)_2Xe$.

The starting point for the synthesis of xenon compounds is the preparation of xenon difluoride, XeF_2, and xenon tetrafluoride, XeF_4, by heating a mixture of the elements to 400°C at 6 atm. At higher pressures, fluorination proceeds as far as xenon hexafluoride, XeF_6. All three fluorides are crystalline solids (Fig. 15.58). In the gas phase, all are molecular compounds. Solid xenon hexafluoride, however, is ionic, with a complex structure consisting of $XeF_5{}^+$ cations bridged by F^- anions.

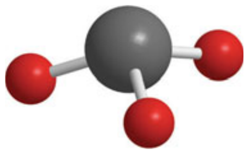
The xenon fluorides are used as powerful fluorinating agents (reagents for attaching fluorine atoms to other substances). The tetrafluoride will even fluorinate platinum metal:

$$Pt(s) + XeF_4(s) \longrightarrow Xe(g) + PtF_4(s)$$

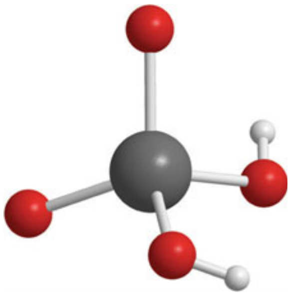
The xenon fluorides are used to prepare the xenon oxides and oxoacids and, in a series of disproportionations, to bring the oxidation number of xenon up to +8. First, xenon tetrafluoride is hydrolyzed to xenon trioxide, XeO_3 in a disproportionation reaction:

$$6\ XeF_4(s) + 12\ H_2O(l) \longrightarrow 2\ XeO_3(aq) + 4\ Xe(g) + 3\ O_2(g) + 24\ HF(aq)$$

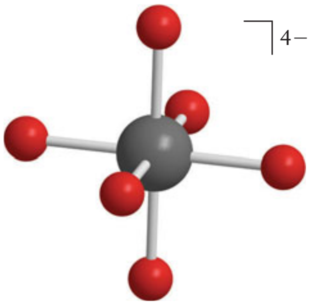
FIGURE 15.58 Crystals of xenon tetrafluoride, XeF_4. This compound was first prepared in 1962 by the reaction of xenon and fluorine at 6 atm and 400°C.



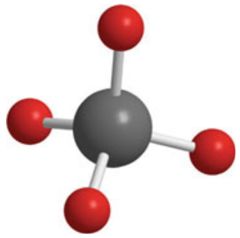
24 Xenon trioxide, XeO_3



25 Xenic acid, H_2XeO_4



26 Perxenate ion, XeO_6^{4-}



27 Xenon tetroxide, XeO_4

Xenon trioxide, XeO_3 (**24**), is the anhydride of xenic acid, H_2XeO_4 (**25**). It reacts with aqueous alkali to form a hydrogen xenate ion, $HXeO_4^-$. This ion slowly disproportionates into xenon and the octahedral perxenate ion, XeO_6^{4-} (**26**), in which the oxidation number of xenon is +8. Aqueous perxenate solutions are yellow and are very powerful oxidizing agents as a result of the high oxidation number of xenon. When barium perxenate is treated with sulfuric acid, it is dehydrated to the anhydride of perxenic acid, xenon tetroxide, XeO_4 (**27**), an explosively unstable gas.

Xenon is the only noble gas known to form an extensive series of compounds with fluorine and oxygen; xenon fluorides are powerful fluorinating agents and xenon oxides are powerful oxidizing agents.

Self-Test 15.18A Explain why the ease of compound formation increases down Group 18/VIII.

[***Answer:*** Ionization energy decreases down the group, and so it is easier for the heavier elements to share their electrons.]

Self-Test 15.18B Predict the shape of the $XeOF_4$ molecule.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Predict and explain trends in the properties and formulas of the main-group elements.

❑ 2 Describe the names, properties, and reactions of the principal compounds of hydrogen and the Period 1 through 3 main group elements.

❑ 3 Describe and write balanced equations for the principal reactions used to produce hydrogen and the Period 1 through 3 main group elements.

❑ 4 Describe the major uses of hydrogen, sodium, potassium, beryllium, magnesium, boron, aluminum, carbon, and silicon.

❑ 5 Describe the reactions of the alkali metals with water and with nonmetals.

❑ 6 Distinguish the allotropes of carbon by their structures.

❑ 7 Explain the differences in reactivity between compounds of carbon and those of silicon.

❑ 8 Rationalize the properties of the oxides and oxoacids of the nonmetals in terms of the oxidation number of the nonmetal and the identification of acid anhydrides.

❑ 9 Describe how nitrogen is obtained from air and converted into useful compounds.

❑ 10 Describe the structures and properties of the nitrogen, phosphorus, and sulfur oxides.

❑ 11 Describe the acidic and basic character of water and hydrogen peroxide and compare their functions as oxidizing and reducing agents.

❑ 12 Explain the low reactivity of the noble gases and the fact that the ease of compound formation increases down the group.

EXERCISES

Periodic Trends

These exercises are a review of principles covered in Chapter 1. See also Exercises 1.87–1.96.

15.1 State which atom of each of the following pairs is larger: (a) fluorine, nitrogen; (b) potassium, calcium; (c) gallium, arsenic; (d) chlorine, iodine.

15.2 State which atom of each of the following pairs is larger: (a) tellurium, tin; (b) silicon, lead; (c) calcium, rubidium; (d) germanium, oxygen.

15.3 State which atom of each of the following pairs is more electronegative: (a) sulfur, phosphorus; (b) selenium, tellurium; (c) sodium, cesium; (d) silicon, oxygen.

15.4 State which atom of each of the following pairs is less electronegative: (a) potassium, rubidium; (b) germanium, bromine; (c) oxygen, selenium; (d) aluminum, silicon.

15.5 Arrange the following atoms in order of increasing first ionization energy: oxygen, tellurium, selenium.

15.6 Arrange the following atoms in order of increasing first ionization energy: boron, thallium, gallium.

15.7 (a) Which atom has the greater electron affinity: phosphorus or antimony? (b) Explain your answer.

15.8 (a) Which atom has the greater electron affinity: germanium or selenium? (b) Explain your answer.

15.9 (a) Which of the following species has the greatest polarizability: chloride ions, bromine atoms, bromide ions? (b) Explain your answer.

15.10 (a) Which of the following species has the greatest polarizing power: rubidium ions, potassium atoms, sodium ions? (b) Explain your answer.

Bonding Trends

15.11 Write the balanced equation for the reaction between potassium and hydrogen.

15.12 Write the balanced equation for the reaction between calcium and hydrogen.

15.13 Classify each of the following compounds as a saline, molecular, or metallic hydride: (a) LiH; (b) NH_3; (c) HBr; (d) UH_3.

15.14 Classify each of the following compounds as a saline, molecular, or metallic hydride: (a) B_2H_6; (b) SiH_4; (c) CaH_2; (d) PdH_x, $x < 1$.

15.15 For each of the following oxides, state whether the compound is acidic, basic, or amphoteric: (a) NO_2; (b) Al_2O_3; (c) $B(OH)_3$; (d) MgO.

15.16 For each of the following oxides, state whether the compound is acidic, basic, or amphoteric: (a) Li_2O; (b) Tl_2O_3; (c) Sb_2O_3; (d) SO_3.

15.17 Give the formula for the formal anhydride of each acid: (a) H_2CO_3; (b) $B(OH)_3$.

15.18 Give the formula for the acid corresponding to each of the following formal anhydrides: (a) N_2O_5; (b) P_4O_{10}; (c) SeO_3.

Hydrogen

15.19 Write a balanced chemical equation for (a) the hydrogenation of ethyne (acetylene, C_2H_2) to ethene (C_2H_4) by hydrogen (give the oxidation number of the carbon atoms in the reactant and product); (b) the shift reaction (sometimes called the water gas shift reaction, WGSR); (c) the reaction of barium hydride with water.

15.20 Write a balanced chemical equation for (a) the reaction between sodium hydride and water; (b) the formation of synthesis gas; (c) the hydrogenation of ethene, $H_2C{=}CH_2$, and give the oxidation number of the carbon atoms in the reactant and product; (d) the reaction of magnesium with hydrochloric acid.

15.21 Identify the products and write a balanced equation for the reaction of hydrogen with (a) chlorine; (b) sodium; (c) phosphorus; (d) copper metal.

15.22 Identify the products and write a balanced equation for the reaction of hydrogen with (a) nitrogen; (b) fluorine; (c) cesium; (d) copper(II) ions.

15.23 The enthalpy of dissociation of hydrogen bonds, ΔH_{HBond}, is a measure of their strength. Explain the trend seen in the data for the following pure substances, which were measured in the gas phase:

Substance	NH_3	H_2O	HF
ΔH_{HBond} **(kJ·mol^{-1})**	17	25	29

15.24 Methanoic acid, HCOOH, forms dimers in the gas phase. Propose a reason for this behavior.

Group 1: The Alkali Metals

15.25 Explain why lithium differs from the other Group 1 elements in its chemical and physical properties. Give two examples to support your explanation.

15.26 (a) Write the valence electron configuration for the alkali metal atoms. (b) Explain why the alkali metals are strong reducing agents in terms of electron configurations, ionization energies, and the hydration of their ions.

15.27 Write the chemical equation for the reaction between (a) sodium and oxygen; (b) lithium and nitrogen; (c) sodium and water; (d) potassium superoxide and water.

15.28 Write the chemical equation for the reaction between (a) cesium and oxygen (cesium reacts with oxygen in the same way as potassium); (b) sodium oxide and water; (c) lithium and hydrochloric acid; (d) cesium and iodine.

Group 2: The Alkaline Earth Metals

15.29 Write the chemical equation for the reaction between magnesium metal and hot water.

15.30 Write the chemical equation for the reaction between barium metal and hydrogen gas.

15.31 The compounds CaO and BaO are sometimes used as drying agents for organic solvents such as pyridine, C_5H_5N. The drying agent and the product of the drying reaction are both insoluble in the organic solvent. (a) Write the balanced chemical equation corresponding to the reaction that dries the solvent. (b) For CaO, determine the standard Gibbs free energy of the drying reaction.

15.32 Aluminum and beryllium have a diagonal relationship. Compare the chemical equations for the reaction of aluminum with aqueous sodium hydroxide to that of beryllium with aqueous sodium hydroxide.

15.33 Predict the products of each of the following reactions and then balance each equation:
(a) $Mg(OH)_2 + HCl(aq) \longrightarrow$
(b) $Ca(s) + H_2O(l) \longrightarrow$
(c) $BaCO_3(s) \longrightarrow$

15.34 Predict the products of each of the following reactions and then balance each equation:
(a) $Mg(s) + Br_2(l) \longrightarrow$
(b) $BaO(s) + Al(s) \longrightarrow$
(c) $CaO(s) + SiO_2(s) \longrightarrow$

15.35 (a) Write the Lewis structures for $BeCl_2$ and $MgCl_2$. How does the Lewis structure of $MgCl_2$ differ from that of $BeCl_2$? (b) Predict the Cl—Be—Cl bond angle. (c) What hybrid orbitals are used in the bonding in $BeCl_2$?

15.36 In the gas phase, $BeCl_2$ forms a dimer by forming chlorine-atom bridges like those in the $AlCl_3$ dimer. Draw the Lewis structure for the $BeCl_2$ dimer and assign formal charges.

Group 13/III: The Boron Family

15.37 Write a balanced equation for the industrial preparation of aluminum from its oxide.

15.38 Write a balanced equation for the industrial preparation of impure boron.

15.39 Complete and balance the following skeletal equations:
(a) $B_2O_3(s) + Mg(l) \longrightarrow$
(b) $Al(s) + Cl_2(g) \longrightarrow$
(c) $Al(s) + O_2(g) \longrightarrow$

15.40 Complete and balance the following skeletal equations:
(a) $Al_2O_3(s) + OH^-(aq) \longrightarrow$
(b) $Al_2O_3(s) + H_3O^+(aq) + H_2O(l) \longrightarrow$
(c) $B(s) + NH_3(g) \longrightarrow$

15.41 Suggest a Lewis structure for B_4H_{10} and deduce the formal charges on the atoms. *Hint:* There are four B—H—B bridges.

15.42 The diatomic molecule BF can be obtained by the reaction between BF_3 and B at a high temperature and low pressure. (a) Determine the electron configuration of the molecule in terms of the occupied molecular orbitals and calculate the bond order. (b) CO is isoelectronic with BF. How do the molecular orbitals in the two molecules differ?

15.43 Many gallium compounds have structures that are similar to those of the corresponding aluminum and boron compounds. Draw the Lewis structure and describe the shape of $GaBr_4^-$.

15.44 Many gallium compounds have structures that are similar to those of the corresponding aluminum and boron compounds. Draw the Lewis structure and describe the shape of Ga_2Cl_6.

Group 14/IV: The Carbon Family

15.45 Describe the sources of silicon and write balanced equations for the three steps in the industrial preparation of silicon.

15.46 Explain why the size of the silicon atom does not permit a silicon analog of the graphite structure.

15.47 Identify the oxidation number of germanium in the following compounds and ions: (a) GeO_4^{4-}; (b) $K_4Ge_4Te_{10}$; (c) Ca_3GeO_5.

15.48 Identify the oxidation number of tin in the following compounds and ions: (a) $Sn_3(OH)_4^{2+}$; (b) K_2SnO_3; (c) $K_2Sn_3O_7$.

15.49 Balance the following skeletal equations and classify them as acid–base or redox:
(a) $MgC_2(s) + H_2O(l) \longrightarrow C_2H_2(g) + Mg(OH)_2(s)$
(b) $Pb(NO)_2(s) \xrightarrow{\Delta} PbO(s) + NO_2(g) + O_2(g)$

15.50 Balance the following skeletal equations and classify them as acid–base or redox:
(a) $CH_4(g) + S_8(s) \longrightarrow CS_2(l) + H_2S(g)$
(b) $Sn(s) + KOH(aq) + H_2O(l) \longrightarrow K_2Sn(OH)_6(aq) + H_2(g)$

15.51 Determine the values of $\Delta H_r°$, $\Delta S_r°$, and $\Delta G_r°$ for the production of high-purity silicon by the reaction $SiO_2(s) + 2\ C(s, graphite) \longrightarrow Si(s) + 2\ CO(g)$ at 25°C and estimate the temperature at which the equilibrium constant becomes greater than 1.

15.52 Determine the values of $\Delta H_r°$, $\Delta S_r°$, and $\Delta G_r°$ for the reaction $2\ CO(g) + O_2(g) \longrightarrow 2\ CO_2(g)$ at 25°C and estimate the temperature at which the equilibrium constant becomes less than 1.

Group 15/V

15.53 Nitrogen can be found in compounds with oxidation numbers ranging from −3 to +5. For each of the possible integral oxidation numbers, give one example of a nitrogen compound or ion.

15.54 Give the oxidation number of phosphorus in (a) white phosphorus; (b) red phosphorus; (c) phosphine, PH_3; (d) diphosphine, P_2H_4; (e) PCl_3; (f) PF_5; (g) phosphate ion, PO_4^{3-}; (h) hydrogen phosphite ion, HPO_3^{2-}.

15.55 Urea, $CO(NH_2)_2$, reacts with water to form ammonium carbonate. Write the chemical equation and calculate the mass of ammonium carbonate that can be obtained from 4.0 kg of urea.

15.56 (a) Nitrous acid reacts with hydrazine in acidic solution to form hydrazoic acid, HN_3. Write the chemical equation and determine the mass of hydrazoic acid that can be produced from 15.0 g of hydrazine. (b) Suggest a method for preparing sodium azide, NaN_3. (c) Is the production of hydrazoic acid an oxidation or a reduction of hydrazine?

15.57 Lead azide, $Pb(N_3)_2$, is used as a detonator. (a) What volume of nitrogen at STP (1 atm, 0°C) does 1.5 g of lead azide produce when it decomposes into lead metal and nitrogen gas? (b) Would 1.5 g of mercury(II) azide, $Hg(N_3)_2$, which is also used as a detonator, produce a larger or smaller volume, given that its decomposition products are elemental mercury and nitrogen gas? (c) Metal azides in general are potent explosives. Why?

15.58 Sodium azide is used to inflate protective air bags in automobiles. What mass of solid sodium azide is needed to provide 100. L of $N_2(g)$ at 1.5 atm and 20.°C?

15.59 The common acid anhydrides of nitrogen are N_2O, N_2O_3, and N_2O_5. Write the formulas of their corresponding acids and chemical equations for the formation of the acids by the reaction of the anhydrides with water.

15.60 The common acid anhydrides of phosphorus are P_4O_6 and P_4O_{10}. Write the formulas of their corresponding acids and chemical equations for the formation of the acids by the reaction of the anhydrides with water.

15.61 The normal boiling point of NH_3 is −33°C and that of NF_3, which has a greater molar mass, is −129°C. Explain this difference.

15.62 Explain the observations that NH_3 is a weak Brønsted base in water whereas NF_3 shows no signs of basicity.

Group 16/VI

15.63 Write equations for (a) the burning of lithium in oxygen; (b) the reaction of sodium metal with water; (c) the reaction of fluorine gas with water; (d) the oxidation of water at the anode of an electrolytic cell.

15.64 Write equations for the reaction of (a) sodium oxide and water; (b) sodium peroxide and water; (c) sulfur dioxide and water; (d) sulfur dioxide and oxygen, with the use of a vanadium pentoxide catalyst.

15.65 Complete and balance each of the following skeletal equations:
(a) $H_2S(aq) + O_2(g) \longrightarrow$
(b) $CaO(s) + H_2O(l) \longrightarrow$
(c) $H_2S(g) + SO_2(g) \longrightarrow$

15.66 Complete and balance each of the following skeletal equations:
(a) $FeS(s) + HCl(aq) \longrightarrow$
(b) $H_2(g) + S_8(s) \longrightarrow$
(c) $Br^- + Cl_2(g) \longrightarrow$

15.67 Explain from structural considerations why the dipole moment of the NH_3 molecule is lower than that of the H_2O molecule.

15.68 Explain from structural considerations why water and hydrogen peroxide have similar physical properties but different chemical properties.

15.69 (a) Write the Lewis structure of H_2O_2 and predict the approximate H—O—O bond angle. Which of the following ions will be oxidized by hydrogen peroxide in acidic solution: (b) Cu^+; (c) Mn^{2+}; (d) Ag^+; (e) F^-?

15.70 (a) Draw the Lewis structure for oleum, $(HO)_2OSOSO(OH)_2$, prepared by treating sulfuric acid with SO_3. (b) Determine the formal charges on the sulfur and oxygen atoms. (c) What is the oxidation number for sulfur in this compound?

15.71 If 2.00 g of sodium peroxide is dissolved to form 200. mL of an aqueous solution, what would be the pH of the solution? For H_2O_2, $K_{a1} = 1.8 \times 10^{-12}$ and K_{a2} is negligible.

15.72 What is the pH of 0.040 M NaHS(aq)?

15.73 Describe the trend in acidity of the binary hydrogen compounds of the Group 16/VI elements and account for the trend in terms of bond strength.

15.74 When lead(II) sulfide is treated with hydrogen peroxide, the possible products are either lead(II) sulfate or lead(IV) oxide and sulfur dioxide. (a) Write balanced equations for the two reactions. (b) Using data available in Appendix 2A, determine which possibility is more likely.

Group 17/VII

15.75 Identify the oxidation number of the halogen in (a) hypoiodous acid; (b) ClO_2; (c) dichlorine heptoxide; (d) $NaIO_3$.

15.76 Identify the oxidation number of the halogen atoms in (a) iodine heptafluoride; (b) sodium periodate; (c) hypobromous acid; (d) sodium chlorite.

15.77 Write the balanced chemical equation for (a) the thermal decomposition of potassium chlorate without a catalyst; (b) the reaction of bromine with water; (c) the reaction between sodium chloride and concentrated sulfuric acid. (d) Identify each reaction as a Brønsted acid–base, Lewis acid–base, or redox reaction.

15.78 Write the balanced chemical equation for the reaction of chlorine with water in (a) a neutral aqueous solution; (b) a dilute basic solution; (c) a concentrated basic solution. (d) Verify that each reaction is a disproportionation reaction.

15.79 (a) Arrange the chlorine oxoacids in order of increasing oxidizing strength. (b) Suggest an interpretation of that order in terms of oxidation numbers.

15.80 (a) Arrange the hypohalous acids in order of increasing acid strength. (b) Suggest an interpretation of that order in terms of electronegativities.

15.81 Write the Lewis structure for Cl_2O. Predict the shape of the Cl_2O molecule and estimate the Cl—O—Cl bond angle.

15.82 Write the Lewis structure for BrF_3. What is the hybridization of the bromine atom in the molecule?

15.83 Suggest reasons why the following interhalogens are not stable: (a) ICl_5; (b) IF_2; (c) $ClBr_3$.

15.84 Chlorine can be found as the following oxoanions: ClO^-, ClO_2^-, ClO_3^-, and ClO_4^- in many chemical stockrooms. However, fluorine forms no stable oxoanions and iodine is never found as IO_4^-. Explain these observations.

15.85 The interhalogen IF_x can be made only by indirect routes. For example, xenon difluoride gas can react with iodine gas to produce IF_x and xenon gas. In one experiment, xenon difluoride is introduced into a rigid container until a pressure of 3.6 atm is reached. Iodine vapor is then introduced until the total pressure is 7.2 atm. Reaction is then allowed to proceed at constant temperature until completion by solidifying the IF_x as it is produced. The final pressure in the flask due to the xenon and excess iodine vapor is 6.0 atm. (a) What is the formula of the interhalogen? (b) Write the chemical equation for its formation.

15.86 The interhalogen ClF_x has been used as a rocket fuel. It reacts with hydrazine to form the gases hydrogen fluoride, nitrogen, and chlorine. In one study of this reaction, ClF_x gas is introduced into a rigid container until a pressure of 1.2 atm is reached. Gaseous hydrazine is then introduced until the total pressure is 3.0 atm. Reaction is then allowed to proceed at constant temperature until completion. The final pressure in the flask is 6.0 atm, which includes 0.9 atm due to excess hydrazine. (a) What is the formula of the interhalogen? (b) Write the chemical equation for its reaction with hydrazine.

15.87 Use data from Appendix 2B to determine whether chlorine gas will oxidize Mn^{2+} to form the permanganate ion in an acidic solution.

15.88 (a) Use the data in Appendix 2B to determine which is the stronger oxidizing agent, ozone or fluorine. (b) Does your answer depend on whether the reaction is carried out in acidic or basic solution?

15.89 The concentration of F^- ions can be measured by adding an excess of lead(II) chloride solution and weighing the lead(II) chlorofluoride (PbClF) precipitate. Calculate the molar concentration of F^- ions in 25.00 mL of a solution that gave a lead chlorofluoride precipitate of mass 0.765 g.

15.90 Suppose 25.00 mL of an aqueous solution of iodine was titrated with 0.0250 M $Na_2S_2O_3(aq)$, with starch as the indicator. The blue color of the starch–iodine complex disappeared when 27.65 mL of the thiosulfate solution had been added. What was the molar concentration of I_2 in the original solution? The titration reaction is $I_2(aq) + 2\,S_2O_3^{2-}(aq) \longrightarrow 2\,I^-(aq) + S_4O_6^{2-}(aq)$.

15.91 Calculate the heat released when ammonium perchlorate (1.00 kg) reacts with aluminum powder (1.00 kg) as rocket fuel: $3\ NH_4ClO_4(s) + 3\ Al(s) \longrightarrow Al_2O_3(s) + AlCl_3(s) + 6\ H_2O(g) + 3\ NO(g)$.

15.92 (a) Using data available in the Appendices, calculate the standard Gibbs free energy of the reaction $Cl_2(g) + H_2O(l) \longrightarrow HClO(aq) + HCl(aq)$ at 298 K. (b) What is the equilibrium constant for this process?

Group 18/VIII

15.93 What are the sources for the production of helium and argon?

15.94 What are the sources for the production of krypton and xenon?

15.95 Determine the oxidation number of the noble gas in (a) KrF_2; (b) XeF_6; (c) KrF_4; (d) XeO_4^{2-}.

15.96 Determine the oxidation number of the noble gas in (a) XeO_3; (b) XeO_6^{4-}; (c) XeF_2; (d) $HXeO_4^{-}$.

15.97 Xenon tetrafluoride is a powerful oxidizing agent. In an acidic solution, it is reduced to xenon. Write the corresponding half-reaction.

15.98 Complete and balance each of the following reactions:
(g) $XeF_6(s) + H_2O(l) \longrightarrow XeO_3(aq) + HF(aq)$
(h) $Pt(s) + XeF_4(s) \longrightarrow$
(i) $Kr(g) + F_2(g) \xrightarrow{\text{electric discharge}}$

15.99 Predict the relative acid strengths of H_2XeO_4 and H_4XeO_6. Explain your conclusions.

15.100 Predict the relative oxidizing strengths of H_2XeO_4 and H_4XeO_6. Explain your conclusions.

Integrated Exercises

15.101 (a) Using graphing software, such as that on the Web site for this book, plot standard potential against atomic number for the elements of Groups 1 and 2 (refer to Appendix 2B for data). (b) What generalizations can be deduced from the graph?

15.102 Using graphing software, such as that on the Web site for this book, and data from Appendix 2B, plot ionization energy against standard potential for the elements of Groups 1 and 2. What generalizations can be drawn from the graph?

15.103 Is there any chemical support for the view that hydrogen should be classified as a member of Group 1? Would it be better to consider hydrogen a member of Group 17/VII? Give evidence that supports each view.

15.104 What justification is there for regarding the ammonium ion as an analog of a Group 1 metal cation? Consider properties such as solubility, charge, and radius. The radius of NH_4^+ is 151 pm.

15.105 Hydrogen burns in an atmosphere of bromine to give hydrogen bromide. If 135 mL of H_2 gas at 273 K and 1.00 atm combines with a stoichiometric amount of bromine and the resulting hydrogen bromide dissolves to form 225 mL of an aqueous solution, what is the molar concentration of the resulting hydrobromic acid solution?

15.106 The saline hydrides all react rapidly with water. They also react similarly with liquid ammonia. (a) Write a balanced equation for the reaction of CaH_2 with liquid ammonia. (b) Would it be best to classify this reaction as redox, Brønsted acid–base, or Lewis acid–base? Explain your answer.

15.107 Infrared radiation is absorbed only when there is a change in the dipole moment of the molecule as the molecule vibrates. Which of the following gases found in the atmosphere can absorb in the infrared region and so function as greenhouse gases: (a) CO; (b) NH_3; (c) CF_4; (d) O_3; (e) Ar? Explain your reasoning. See Box 15.1.

15.108 Carbon dioxide absorbs infrared energy during bending or stretching motions that are accompanied by a change in dipole moment (from zero). Which of the transitions pictured in Fig. 2b of Major Technique 1, following Chapter 2, can absorb infrared radiation? Explain your reasoning. See Box 15.1.

15.109 Methanol, CH_3OH, is a clean-burning liquid fuel being considered as a replacement for gasoline. Calculate the theoretical yield in kilograms of CO_2 produced by the combustion of 1.00 L of methanol (of density $0.791\ g\cdot cm^{-3}$) and compare it with the 2.16 kg of CO_2 generated by the combustion of 1.00 L of octane. Which fuel contributes more CO_2 per liter to the atmosphere when burned? What other factors would you take into consideration when deciding which of the two fuels to use? See Box 15.1.

15.110 The standard enthalpy of formation of $SiCl_4(g)$ is $-662.75\ kJ\cdot mol^{-1}$ and its standard molar entropy is $+330.86\ J\cdot K^{-1}\cdot mol^{-1}$. Calculate the temperature at which the reduction of $SiCl_4(g)$ with hydrogen gas to Si(s) and HCl(g) becomes spontaneous.

15.111 (a) Examine the structures of diborane, B_2H_6, and Al_2Cl_6. Compare the bonding in these two compounds. How are they similar? (b) What are the differences, if any, in the types of bonds formed? (c) What is the hybridization of the Group 13/III element? (d) Are the molecules planar? If not, describe their shapes.

15.112 (a) Draw the Lewis structure and assign a hybridization scheme to the atoms in the P_4 molecule. (b) Explain why the bonds in this molecule are thought to be strained.

15.113 Like elements, molecules have ionization energies. (a) Define the ionization energy of a molecule. (b) Predict which of these compounds has a higher ionization energy and justify your prediction: $SiCl_4$ or SiI_4.

15.114 Isoelectronic species have the same number of electrons. (a) Divide the following species into two isoelectronic groups: CN^-, N_2, NO_2^-, C_2^{2-}, O_3. Which species in each group is likely to be (b) the strongest Lewis base; (c) the strongest reducing agent?

15.115 Isoelectronic species have the same number of electrons. (a) Divide the following species into three isoelectronic groups: NH_3, NO, NO_2^+, N_2O, H_3O^+, O_2^+. (b) Which species in each group is likely to be (b) the strongest Lewis acid; (c) the strongest oxidizing agent?

15.116 The ground state of O_2 has two unpaired π^* electrons with parallel spins. There are two known low-lying excited states of O_2. State A has the two π^* electrons with the spins antiparallel but in different orbitals. State B has the two π^* electrons paired in the same orbital. (a) The energies of the excited states are $94.72\ kJ\cdot mol^{-1}$ and $157.85\ kJ\cdot mol^{-1}$ above the ground state. Which state corresponds to which excitation energy? (b) What is the wavelength of the radiation absorbed in the transition from the ground state to the first excited state?

15.117 Thiosulfuric acid, $H_2S_2O_3$, has a structure similar to that of sulfuric acid, except that the terminal oxygen atom has been replaced by a sulfur atom. How would you expect the physical and chemical properties of thiosulfuric acid and sulfuric acid to differ?

15.118 The concentration of Cl^- ions can be measured gravimetrically by precipitating silver chloride, with silver nitrate as the precipitating reagent in the presence of dilute nitric acid. The white precipitate is filtered off and its mass is determined. (a) Calculate the Cl^- ion concentration in 50.00 mL of a solution that gave a silver chloride precipitate of mass 1.972 g. (b) Why is the method inappropriate for measuring the concentration of fluoride ions?

15.119 Xenon fluorides are used as fluorinating agents for organic and inorganic compounds. Xenon tetrafluoride reacts with sulfur tetrafluoride to produce sulfur hexafluoride and xenon. What mass of sulfur hexafluoride can be produced from 330.0 g of xenon tetrafluoride and 250.0 g of sulfur tetrafluoride?

15.120 (a) When Xe and Pt are treated with fluorine gas under pressure at 200°C, the ionic solid $XeF_5{}^+PtF_6{}^-$ is formed. Write the Lewis structure for $XeF_5{}^+$ and, from VSEPR theory, predict its shape. (b) When two molecules of XeF_2 react with one molecule of AsF_5, the resulting compound has the formula $Xe_2F_3{}^+AsF_6{}^-$. Predict the Lewis structure of the $Xe_2F_3{}^+$ ion.

15.121 (a) Consider the substances shown in parts (a), (c), and (d) in the second illustration in Box 15.2. (b) In which of these three parts of the figure will the interactions be the strongest? (c) In which will they be the weakest?

15.122 Chapter 15 has been organized by group. Discuss whether it would be helpful to organize the elements according to period and give examples of trends that could be displayed helpfully in that way.

15.123 The azide ion has an ionic radius of 148 pm and forms many ionic and covalent compounds that are similar to those of the halides. (a) Write the Lewis formula for the azide ion and predict the N—N—N bond angle. (b) On the basis of its ionic radius, where in Group 17/VII would you place the azide ion? (c) Compare the acidity of hydrazoic acid with those of the hydrohalic acids and explain any differences (for HN_3, $K_a = 1.7 \times 10^{-5}$). (d) Write the formulas of three ionic or covalent azides.

15.124 The concentration of nitrate ion can be determined by a multistep process. A 25.00-mL sample of water from a rural well contaminated with $NO_3{}^-(aq)$ was made basic and treated with an excess of zinc metal, which reduces the nitrate ion to aqueous ammonia. The evolved ammonia gas was passed into 50.00 mL of 2.50×10^{-3} M HCl(aq). The unreacted HCl(aq) was titrated to the stoichiometric point with 28.22 mL of 1.50×10^{-3} M NaOH(aq). (a) Write balanced chemical equations for the three reactions. (b) What is the molar concentration of nitrate ion in the well water?

15.125 Account for the observation that solubility in water generally increases from chloride to iodide for ionic halides with low covalent character (such as the potassium halides) but decreases from chloride to iodide for ionic halides in which the bonds are significantly covalent (such as the silver halides).

15.126 Account for the observation that melting and boiling points generally decrease from fluoride to iodide for ionic halides but increase from fluoride to iodide for molecular halides.

15.127 The nitrosyl ion, NO^+, is isoelectronic with N_2 and has two fewer electrons than O_2. The ion is stable and can be purchased as its hexafluorophosphate ($PF_6{}^-$) or tetrafluoroborate ($BF_4{}^-$) salt. (a) Draw its molecular orbital diagram and compare it with those of N_2 and O_2. (b) NO^+ is diamagnetic. Can we tell which orbital, the σ_{2p} or the π_{2p}, is higher in energy from this information?

15.128 (a) Draw the molecular orbital energy-level diagram for O_2. Using the diagram, determine the bond order and magnetic properties of O_2. (b) What molecular property of oxygen is explained by its molecular orbital diagram but not by its Lewis structure? (c) Describe the nature of the highest occupied molecular orbital—is it bonding, antibonding, or nonbonding? (d) Predict the bond order and magnetic properties of the peroxide ion and the superoxide ion on the basis of molecular orbital theory.

Chemistry Connections

15.129 The gas NO is released to the stratosphere by jet engines. Because it can contribute to the destruction of stratospheric ozone, its concentration is monitored closely. One monitoring technique measures the chemiluminescence given off by the reaction $NO(g) + O_3(g) \longrightarrow NO_2{}^*(g) + O_2(g)$. The asterisk indicates that NO_2 is produced in an excited state. The excited NO_2 molecule gives off red light and infrared radiation as it returns to the ground state. Because both NO and NO_2 may be present in the air sample, part of the sample is exposed to a reducing agent, which converts all of the NO_2 to NO. Two samples are then analyzed, first air from the unreduced original sample, which gives the concentration of NO, then air from the reduced sample. The concentration of NO_2 in the air is the difference of the two measurements. In one experiment, two samples were collected, one from a cloud and one from clear air. The following measurements were made at 9 km above the Pacific Ocean (ppt denotes parts per trillion, by molecules):

	Unreduced sample	Reduced sample
Cloud:	860 ppt	1110 ppt
Clear air:	480 ppt	740 ppt

(a) Determine the concentrations (in ppt) of NO and NO_2 in each air sample.
(b) In which part of the atmosphere is the concentration of NO greater?
(c) Explain the difference, taking into account other sources of NO in the atmosphere besides airplanes.
(d) Some of the NO molecules released by jet engines react with the hydroxyl radical, ·OH. Write the Lewis structure of the most likely product and state its name.
(e) Is the product of the reaction in part (d) likely to be more stable than NO? Explain your reasoning.
(f) In the stratosphere NO catalyzes the conversion of O_3 to O_2 in a two-step reaction with the intermediate NO_2. The overall equation for the reaction is $O_3(g) + O(g) \longrightarrow 2\,O_2(g)$ and the rate law for the reaction is Rate $= k\,[NO][O_3]$. Write an acceptable two-step mechanism for the reaction, indicating which step is the slow step.
(g) At −30°C, the temperature of the air from which the samples were taken, the rate constant for the reaction in part (f) is 6×10^{-15} cm^3·molecule^{-1}·s^{-1}. If the concentration of ozone in the air from which the NO clear air sample was taken was 4×10^{-12} molecules·cm^{-3} and the total pressure of the air was 220 mbar, what was the rate at which ozone was being destroyed in the air at −30°C?

THE ELEMENTS: THE d-BLOCK

Chapter 16

THE d-BLOCK ELEMENTS AND THEIR COMPOUNDS
16.1 Trends in Physical Properties
16.2 Trends in Chemical Properties
SELECTED ELEMENTS: A SURVEY
16.3 Scandium Through Nickel
16.4 Groups 11 and 12
COORDINATION COMPOUNDS
16.5 Coordination Complexes
16.6 The Shapes of Complexes
16.7 Isomers
THE ELECTRONIC STRUCTURES OF COMPLEXES
16.8 Crystal Field Theory
16.9 The Spectrochemical Series
16.10 The Colors of Complexes
16.11 Magnetic Properties of Complexes
16.12 Ligand Field Theory

What Are the Key Ideas? The properties of the d-block elements are governed by the availability of d-orbitals, their variable valence, and their ability to act as Lewis acids and form a wide variety of complexes.

Why Do We Need to Know This Material? The d-block metals are the workhorse elements of the periodic table. Iron and copper helped civilization rise from the Stone Age and are still our most important industrial metals. Other members of the block include the metals of new technologies, such as titanium for the aerospace industry and vanadium for catalysts in the petrochemical industry. The precious metals silver, platinum, and gold are prized as much for their appearance, rarity, and durability as for their usefulness. Compounds of d-block metals give color to paint, turn sunlight into electricity, serve as powerful oxidizing agents, and form the basis of some cancer treatments.

What Do We Need to Know Already? This chapter draws on many of the principles introduced in the preceding chapters. In particular, it makes use of the electron configurations of atoms and ions (Sections 1.13 and 2.1) and the classification of species as Lewis acids and bases (Section 11.2). Molecular orbital theory (Sections 3.8 through 3.12) plays an important role in Section 16.12.

The transformation of the past by the Industrial Revolution was made possible by the development of steel, an iron alloy used for construction and transportation. Other d-block metals, both as the elements and in compounds, are transforming our present. Copper, for instance, is an essential component of some superconductors. The d-block metals will also help to shape our future. For example, vanadium and platinum are used in the development of catalysts to reduce pollution and in the continuing effort to make hydrogen a practical and economical fuel.

The compounds of the d-block elements show a wide range of interesting properties. Some are vital to life. Iron is an essential component of mammalian blood. Compounds of cobalt, molybdenum, and zinc are found in vitamins and essential enzymes. Other compounds simply make life more interesting and colorful. The beautiful color of cobalt blue glass, the brilliant greens and blues of kiln-baked pottery, and many pigments used by artists make use of d-block compounds.

We begin this chapter by summarizing the major periodic trends exhibited by the d-block elements and their compounds. Then we describe some of the properties and key reactions of selected elements. The d-block metals form a wide variety of complexes and, in the second half of the chapter, we describe their shapes and the two principal theories of their electronic structure. Some of the contributions of the d-block metals to the formulation of modern materials have already been described in Chapter 6.

THE d-BLOCK ELEMENTS AND THEIR COMPOUNDS

The elements in Groups 3 through 11 are called the *transition metals* because they represent a transition from the highly reactive metals of the s-block to the much less reactive metals of Group 12 and the p-block (Fig. 16.1). Note that the transition metals do not extend all the way across the d-block: the Group 12 elements (zinc, cadmium, and mercury) are not normally considered to be transition elements. Because their d-orbitals are full and except in rare instances do not participate in bonding, the Group 12 elements have properties that are more like those of main-group metals than those of transition metals. Just after the third row of the d-block has been started, following lanthanum, electrons begin to occupy the seven 4f-orbitals and the lanthanoids (the “rare earths”;

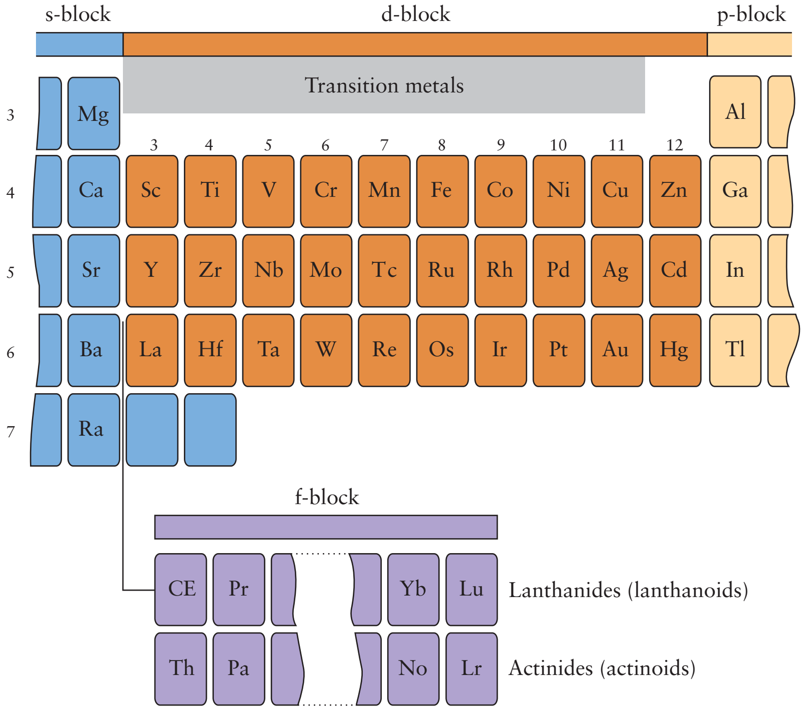


FIGURE 16.1 The orange rectangles identify the elements in the d-block of the periodic table. Note that the f-block, consisting of the inner transition metals, intervenes in Periods 6 and 7 as indicated by the purple bar. The horizontal gray bar designates the groups containing transition metals, Groups 3–11.

commonly known as the lanthanides) delay the completion of Period 6. These elements, together with the actinoids (commonly called the actinides), the analogous series in Period 7, are sometimes referred to as the *inner transition metals*.

Some periodic charts designate the elements La–Yb as the f-block. In this book, the elements Ce–Lu are designated as the f-block to be consistent with IUPAC conventions.

Electron transitions within the incompletely filled d-subshell are responsible for many of the colors shown by compounds of the d-block elements. Furthermore, many d-block compounds are paramagnetic (see Box 3.2). One of the challenges that we face in this chapter is to build a model of bonding that accounts for color and magnetism in a unified way. First, though, we consider the physical and chemical properties of the elements themselves.

16.1 Trends in Physical Properties

The ground-state electron configurations of the atoms of d-block elements differ primarily in the occupation of the $(n - 1)$d-orbitals. According to the rules of the building-up principle, these orbitals are the last orbitals to be occupied. However, once they are occupied, they lie slightly lower in energy than the outer ns-orbitals. Because there are five d-orbitals in a given shell, and each one can accommodate up to two electrons, there are 10 elements in each row of the d block. The electron configurations of the d-block metals differ primarily in the occupation of these inner d-orbitals, and so the physical properties of the elements tend to be similar.

All the d-block elements are metals. Most of these so-called "d-metals" are good electrical conductors. In fact, at room temperature silver is the best electrical conductor of all metals. Most of the d-metals are malleable, ductile, lustrous, and silver-white in color. Generally, their melting and boiling points are higher than those of the main-group elements. There are a few notable exceptions: copper is red-brown, gold is yellow, and mercury has such a low melting point that it is a liquid at room temperature.

The shapes of the d-orbitals affect the properties of the d-block elements in two ways (see Fig. 1.37):

- The lobes of two d-orbitals on the same atom occupy markedly different regions of space. As a result, electrons in different d-orbitals are relatively far apart and repel one another only weakly.
- The electron density in d-orbitals is low near the nucleus, and so they are not very effective at shielding other electrons from the positive nuclear charge.

One consequence of these two characteristics is the trend in atomic radii of the d-block metals, which decrease gradually across a period and then rise again (Fig. 16.2). Nuclear charge and number of d-electrons both increase from left to right across each row (from scandium to zinc, for instance). Because the repulsion between d-electrons is weak, initially the increasing nuclear charge can draw them inward, and so the atoms become smaller. Farther across the block, there are so many d-electrons that electron–electron repulsion increases more rapidly than the attraction from the nuclear charge, and the radii begin to increase again. Because these attractions and repulsions are finely balanced, the range of d-metal atomic radii is not very great. In fact, some of the atoms of one d-metal can easily replace atoms of another d-metal in a crystal lattice (Fig. 16.3). The d-metals can therefore form a wide range of alloys, including the many varieties of steel (see Sections 6.1–6.4).

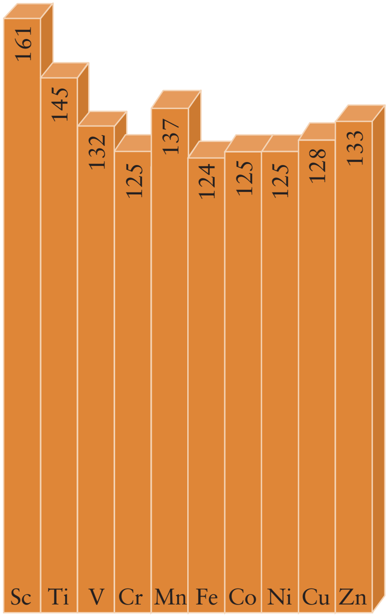

FIGURE 16.2 The atomic radii (in picometers) of the elements of the first row of the d-block.

The atomic radii of the second row of d-metals (Period 5) are typically greater than those in the first row (Period 4). The atomic radii in the third row (Period 6), however, are about the same as those in the second row and smaller than expected. This effect is due to the **lanthanide contraction,** the decrease in radius along the first row of the f-block (Fig. 16.4). This decrease is due to the increasing nuclear charge along the period coupled with the poor shielding ability of f-electrons. When the d-block resumes (at hafnium), the atomic radius has fallen from 188 pm for lanthanum to 156 pm for hafnium.

A technologically important effect of the lanthanide contraction is the high density of the Period 6 elements (Fig. 16.5). The atomic radii of these elements are comparable to those of the Period 5 elements, but their atomic masses are about twice as large; so more mass is packed into the same volume. A block of iridium, for example, contains about as many atoms as a block of rhodium of the same volume. However, each iridium atom is nearly twice as heavy as a rhodium atom, and so the density of the sample is nearly twice as great. In fact, iridium is one of the two densest elements; its neighbor osmium is the other. Another effect of the contraction is the low reactivity—the "nobility"—of gold and platinum. Because their valence electrons are relatively close to the nucleus, they are tightly bound and not readily available for chemical reactions.

The atomic radii of the d-block metals are similar but tend to decrease across a series. The lanthanide contraction accounts for the smaller than expected radii and higher densities of the d-block atoms in Period 6.

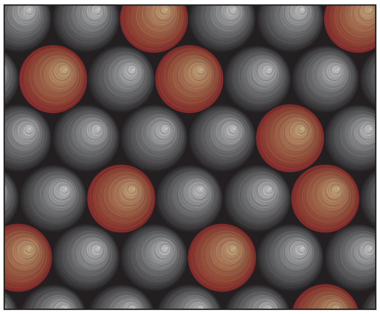

FIGURE 16.3 Because the atomic radii of the d-block elements are so similar, the atoms of one element can replace the atoms of another element with minor modification of the atomic locations; consequently, d-block metals form a wide range of alloys.

16.2 Trends in Chemical Properties

The d-block elements tend to lose their valence s-electrons when they form compounds. Most of them can also lose a variable number of d-electrons and exist in a variety of oxidation states. The only elements of the block that do not use their d-electrons in compound formation are the members of Group 12. Zinc and cadmium lose only their s-electrons; mercury loses a d-electron only in rare instances. The ability to exist in different oxidation states is responsible for many of the special chemical properties of these elements and plays a role in the action of many biomolecules.

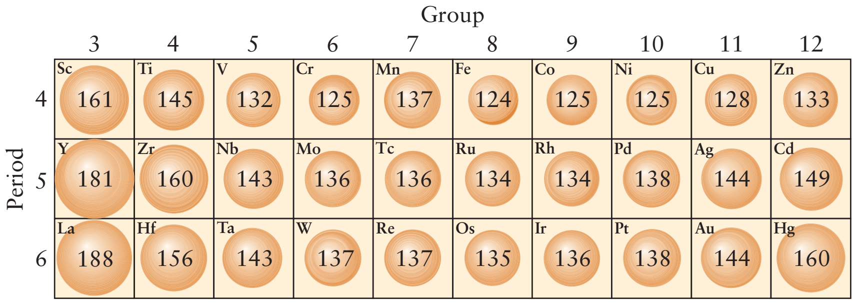

FIGURE 16.4 The atomic radii of the d-block elements (in picometers). Notice the similarity of all the values and, in particular, the close similarity between the second and the third rows as a result of the lanthanide contraction.

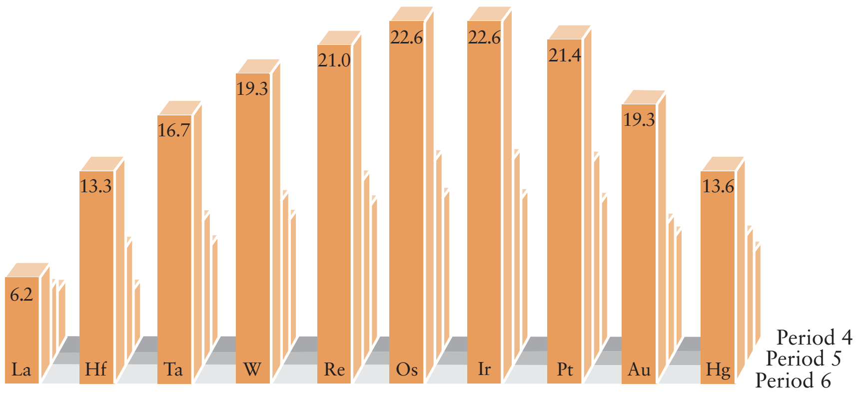

FIGURE 16.5 The densities (in grams per centimeter cubed, $g \cdot cm^{-3}$) of the d-metals at 25°C. The lanthanide contraction has a pronounced effect on the densities of the elements in Period 6 (front row in this illustration), which are among the densest of all the elements.

Most d-block elements have more than one common oxidation state (Fig. 16.6). The distribution of oxidation states looks daunting at first sight, but if we examine the figure, we can see two patterns:

1 Elements close to the center of each row have the widest range of oxidation states.

Except for mercury, the elements at the ends of each row of the d-block occur in only one oxidation state other than 0. All the other elements of each row are found in at least two oxidation states and manganese, at the center of its row, is found in seven oxidation states.

2 Elements in the second and third rows of the block are more likely to reach higher oxidation states than are those in the first row.

Notice that ruthenium and osmium have all possible oxidation states and that even gold and mercury, which lie near the end of the block, can be found in three oxidation states.

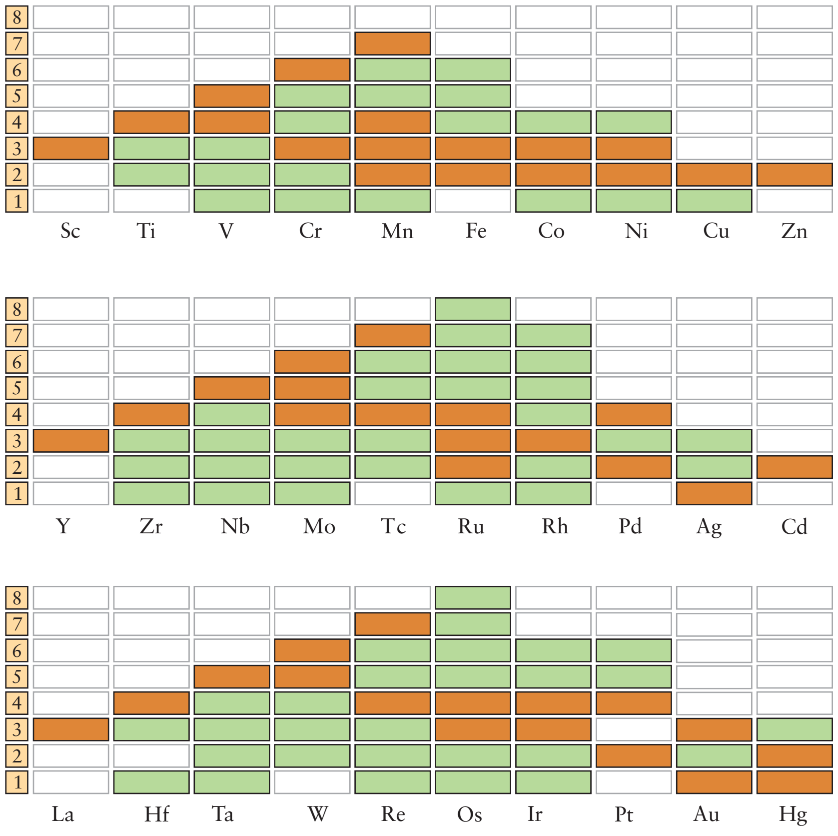

FIGURE 16.6 The oxidation numbers of the d-block elements. The orange blocks mark the common oxidation numbers for each element; the green blocks mark the other known states.

The pattern of oxidation states underlies trends in the chemical properties of the d-block elements. An element in a high oxidation state is easily reduced; therefore, the compound is likely to be a good oxidizing agent. For example, manganese has oxidation number +7 in the permanganate ion, MnO_4^- and this ion is a good oxidizing agent in acidic solution:

$$MnO_4^-(aq) + 8\,H^+(aq) + 5\,e^- \longrightarrow Mn^{2+}(aq) + 4\,H_2O(l) \qquad E° = +1.51\text{ V}$$

Compounds that contain the element in a low oxidation state, such as Cr^{2+}, are often good reducing agents:

$$Cr^{3+}(aq) + e^- \longrightarrow Cr^{2+}(s) \qquad E° = -0.41\text{ V}$$

The pattern of oxidation states correlates with the pattern of acid–base behavior of d-metal oxides. Although most d-metal oxides are basic, the oxides of a given element show a shift toward acidic character with increasing oxidation number, just as the oxoacids do (recall Section 11.10). The family of chromium oxides is a good example:

CrO	+2	basic
Cr_2O_3	+3	amphoteric
CrO_3	+6	acidic

Chromium(VI) oxide, CrO_3, is the anhydride of chromic acid, H_2CrO_4, the parent acid of the chromates. In this highly oxidized state, chromium is electron poor and the oxygen atoms attached to it are less likely to share electrons with a proton.

The elements on the left of the d-block resemble the s-block metals in being much more difficult to extract from their ores than the metals on the right. Indeed, if we go to the right side of the d-block and move back across it from right to left, we encounter the elements in very roughly the order in which they were put to use as metals. On the far right are copper and zinc, which jointly were responsible for the Bronze Age. As metal workers discovered how to achieve higher temperatures, they found out how to reduce iron oxides, and the Bronze Age was succeeded by the Iron Age. The metals at the left of the block—for example, titanium—require such extreme conditions for their extraction—including the use of other active metals or electrolysis—that they became widely available only in the twentieth century, when these techniques were developed.

Self-Test 16.1A Predict trends in ionization energies of the d-block metals.

[***Answer:*** Ionization energy increases from left to right across a row and decreases down a group.]

Self-Test 16.1B Six of the d-block metals in Period 4 form +1 ions. Predict trends in the radii of those ions.

The range of oxidation states of a d-block element increases toward the center of the block. Compounds in which the d-block element has a high oxidation state tend to be oxidizing; those in which it has a low oxidation state tend to be reducing. The acidic character of oxides increases with the oxidation state of the element.

SELECTED ELEMENTS: A SURVEY

Although the physical properties of the d-block elements are similar, the chemical properties of these elements are so diverse that it is impossible to summarize them briefly. We can, however, illustrate some of the major trends in properties within the d-block by considering the properties of certain representative elements, particularly those in the first row of the block.

16.3 Scandium Through Nickel

Table 16.1 summarizes the physical properties of the elements from scandium through nickel. Notice the similarities in their melting and boiling points, but the gradual increase in density.

TABLE 16.1 Properties of the d-Block Elements Scandium Through Nickel

Z	Name	Symbol	Valence electron configuration	Melting point (°C)	Boiling point (°C)	Density, ($g \cdot cm^{-3}$)
21	scandium	Sc	$3d^1 4s^2$	1540	2800	2.99
22	titanium	Ti	$3d^2 4s^2$	1660	3300	4.55
23	vanadium	V	$3d^3 4s^2$	1920	3400	6.11
24	chromium	Cr	$3d^5 4s^1$	1860	2600	7.19
25	manganese	Mn	$3d^5 4s^2$	1250	2120	7.47
26	iron	Fe	$3d^6 4s^2$	1540	2760	7.87
27	cobalt	Co	$3d^7 4s^2$	1494	2900	8.80
28	nickel	Ni	$3d^8 4s^2$	1455	2150	8.91

Scandium, Sc, which was first isolated in 1937, is a reactive metal: it reacts with water about as vigorously as calcium does. It has few uses and is not thought to be essential to life. The small, highly charged Sc^{3+} ion is strongly hydrated in water (like Al^{3+}), and the resulting $[Sc(OH_2)_6]^{3+}$ complex is about as strong a Brønsted acid as acetic acid.

Square brackets are commonly used to indicate the presence of a d-metal complex.

A note on good practice: When water is part of a complex, its formula is written OH_2 to emphasize that the water molecule links to the metal through the O atom.

Titanium, Ti, a light, strong metal, is used where these properties are critical—in widely diverse applications such as jet engines and dental fixtures such as partial plates. Although titanium is relatively reactive, unlike scandium it is resistant to corrosion because it is passivated by a protective skin of oxide on its surface. The principal sources of the metal are the ores *ilmenite*, $FeTiO_3$, and *rutile*, TiO_2.

Thinking point: Can you think of a reason why some metals are passivated by an oxide film but others not?

Titanium requires strong reducing agents for extraction from its ores. It was not widely exploited commercially until demand from the aerospace industry increased in the last part of the twentieth century. The metal is obtained by first treating the ores with chlorine in the presence of coke (impure carbon obtained by heating coal in the absence of air) to form titanium(IV) chloride; the volatile chloride is then reduced by passing it through liquid magnesium:

$$TiCl_4(g) + 2\ Mg(l) \xrightarrow{700°C} Ti(s) + 2\ MgCl_2(s)$$

The most common oxidation state of titanium is +4, in which the atom has lost both its 4s-electrons and its two 3d-electrons. Its most important compound is titanium(IV) oxide, TiO_2, which is almost universally known as titanium dioxide. This oxide is a brilliantly white (when finely powdered), nontoxic, stable solid used as the white pigment in paints and paper. It acts as a semiconductor in the presence of light, and so it is used to convert solar radiation into electrical energy in solar cells.

Thinking point: Why is finely divided titanium oxide powder white?

Titanium forms a series of oxoanions called *titanates*, which are prepared by heating TiO_2 with a stoichiometric amount of the oxide or carbonate of a second metal. One of these compounds, barium titanate, $BaTiO_3$, is **piezoelectric,** which means that it becomes electrically polarized when it is mechanically distorted. The ability to convert mechanical vibration into an electrical signal makes barium titanate useful for underwater sound detection.

Vanadium, V, a soft silver-gray metal, is produced by reducing its oxide or chloride. For example, vanadium(V) oxide is reduced by calcium:

$$V_2O_5(s) + 5\ Ca(l) \xrightarrow{\Delta} 2\ V(s) + 5\ CaO(s)$$

Vanadium is used to make tough steels for automobile and truck springs. Because it is not economical to add the pure metal to iron, a **ferroalloy** of the metal, an alloy with iron and carbon, that is less expensive to produce, is used instead.

FIGURE 16.7 Many vanadium compounds form vividly colored solutions in water. They are also used in pottery glazes. The blue colors here are due to the vanadyl ion, VO^{2+}.

Vanadium(V) oxide, V_2O_5, commonly known as vanadium pentoxide, is the most important compound of vanadium. This orange-yellow solid is used as an oxidizing agent and as an oxidizing catalyst (a catalyst that accelerates oxidation) in the contact process for the manufacture of sulfuric acid (Section 15.21). The wide range of colors of vanadium compounds, including the blue of the vanadyl ion, VO^{2+} (Fig. 16.7), has led to their use as glazes in the ceramics industry.

Chromium, Cr, is a bright, lustrous, corrosion-resistant metal. Its name, which comes from the Greek word for "color," was inspired by its colorful compounds. The metal is obtained from the black mineral *chromite*, $FeCr_2O_4$, by reduction with carbon in an electric arc furnace:

$$FeCr_2O_4(s) + 4\,C(s) \xrightarrow{\Delta} Fe(l) + 2\,Cr(l) + 4\,CO(g)$$

A less abundant source of chromium is the green mineral *chrome ochre*, Cr_2O_3, which is reduced to the metal by aluminum in the thermite process:

$$Cr_2O_3(s) + 2\,Al(s) \xrightarrow{\Delta} Al_2O_3(s) + 2\,Cr(l)$$

Chromium metal is important in metallurgy, because it is used to make stainless steel and for chromium plating (Section 13.13). Chromium(IV) oxide, CrO_2, a brown-black solid, is a ferromagnetic material that is used for coating "chrome" recording tapes.

Ferromagnetism is described in Section 6.16.

Sodium chromate, Na_2CrO_4, a yellow solid, is the source of most other chromium compounds, including fungicides, pigments, and ceramic glazes. The chromate ion changes into the orange dichromate ion, $Cr_2O_7^{2-}$, in the presence of acid (Fig. 16.8):

$$2\,CrO_4^{2-}(aq) + 2\,H^+(aq) \longrightarrow Cr_2O_7^{2-}(aq) + H_2O(l)$$

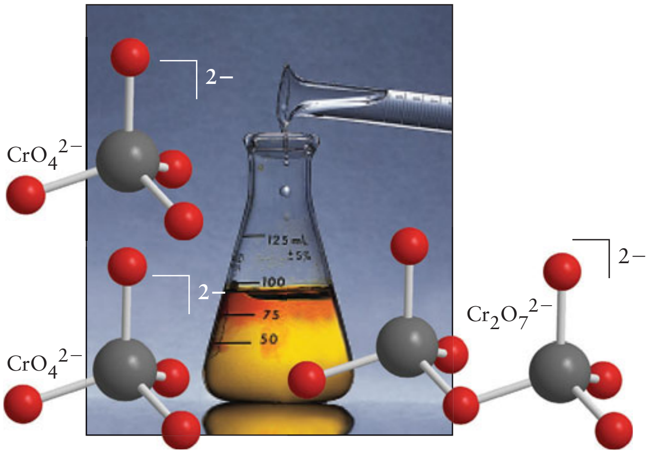

FIGURE 16.8 The chromate ion, CrO_4^{2-}, is yellow. When acid is added to a chromate solution, the ions form orange dichromate ions, $Cr_2O_7^{2-}$.

TABLE 16.2 Composition of Different Steels

Element blended into iron	Typical amount (%)	Effect
manganese	0.5 to 1.0	increases strength and hardness but lowers ductility
	13	increases wear resistance
nickel	<5	increases strength and shock resistance
	>5	increases corrosion resistance (stainless) and hardness
chromium	variable	increases hardness and wear resistance
	>12	increases corrosion resistance (stainless)
vanadium	variable	increases hardness
tungsten	<20	increases hardness, especially at high temperatures

In the laboratory, acidified solutions of dichromates, in which the oxidation number of chromium is +6, are useful oxidizing agents:

$$Cr_2O_7^{2-}(aq) + 14\ H^+(aq) + 6\ e^- \longrightarrow 2\ Cr^{3+}(aq) + 7\ H_2O(l) \qquad E° = +1.33\ V$$

Manganese, Mn, is a gray metal that resembles iron. It is much less resistant to corrosion than chromium is and becomes coated with a thin brown layer of oxide when exposed to air. The metal is rarely used alone, but it is an important component of alloys. When it is added to iron as ferromanganese to make steel, it reacts with sulfur present as an impurity. Both FeS and MnS collect in the cracks between the grains of steel, but whereas FeS melts at a low temperature and allows the cracks to spread, MnS does not and its inclusion is not a problem. Manganese also increases iron's hardness, toughness, and resistance to abrasion (Table 16.2). Another useful alloy is *manganese bronze* (39% by mass Zn, 1% Mn, a small amount of iron and aluminum, and the rest copper), which is very resistant to corrosion and is used for the propellers of ships. Manganese is also alloyed with aluminum to increase the stiffness of beverage cans, allowing them to be manufactured with thinner walls.

A rich supply of manganese lies in nodules of ore that litter the ocean floors (Fig. 16.9). These nodules range in diameter from millimeters to meters and are lumps of the oxides of iron, manganese, and other elements. However, because this source is technically difficult to exploit, manganese is currently obtained by the thermite process from *pyrolusite*, a mineral form of manganese dioxide:

$$3\ MnO_2(s) + 4\ Al(s) \xrightarrow{\Delta} 3\ Mn(l) + 2\ Al_2O_3(s)$$

Manganese lies near the center of its row (in Group 7) and occurs in a wide variety of oxidation states. The most stable state is +2, but +4, +7, and, to a lesser extent, +3 are common in manganese compounds. Its most important compound is manganese(IV) oxide, MnO_2, commonly called manganese dioxide. This compound is a brown-black solid used in dry cells, as a decolorizer to conceal the green tint of glass, and as the starting point for the production of other manganese compounds.

FIGURE 16.9 Manganese nodules that litter the ocean floor are potentially a valuable source of the element.

Potassium permanganate is a strong oxidizing agent in acidic solution and is used to oxidize organic compounds and as a mild disinfectant. Its usefulness stems not only from its thermodynamic tendency to oxidize other species but also from its ability to act by a variety of mechanisms; hence, it is likely to be able to find a path with low activation energy and act rapidly.

Iron, Fe, the most widely used of all the d-metals, is the most abundant element on Earth and the second most abundant metal in the Earth's crust (after aluminum). Its principal ores are the oxides *hematite*, Fe_2O_3, and *magnetite*, Fe_3O_4, which are used to make steel. The sulfide mineral *pyrite*, FeS_2 (see Fig. 15.42), is widely available, but it is not used in steelmaking because the sulfur is difficult to remove.

The production of steel (see Section 6.3) is so important to modern society that it is used as a measure of a country's economic power. The process begins with the mining of iron ore, generally as the oxide Fe_2O_3, which is reduced through a series of redox and Lewis acid–base reactions. A mixture of iron ore, coke, and limestone

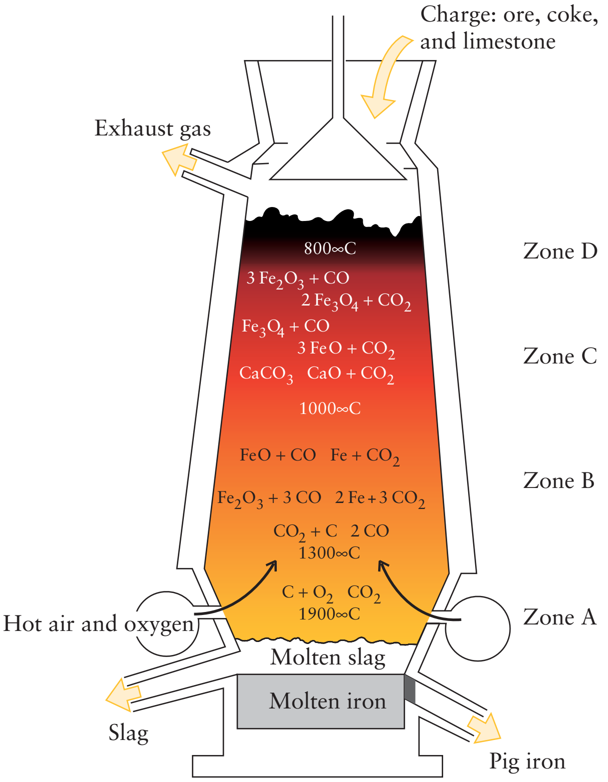

FIGURE 16.10 The reduction of iron ore takes place in a blast furnace containing a mixture of the ore with coke and limestone. Different reactions take place in different zones when the blast of air and oxygen is admitted. The ore, an oxide, is reduced to the metal by reduction with carbon monoxide produced in the furnace.

(calcium carbonate, see Section 6.6) is fed continuously into the top of a blast furnace (Fig. 16.10), which is approximately 40 m high. Each kilogram of iron produced requires about 1.75 kg of ore, 0.75 kg of coke, and 0.25 kg of limestone. The limestone undergoes thermal decomposition to calcium oxide (lime) and carbon dioxide. The calcium oxide, which contains the Lewis base O^{2-}, helps to remove the acidic (nonmetal oxide) and amphoteric impurities from the ore:

$$CaO(s) + SiO_2(s) \xrightarrow{\Delta} CaSiO_3(l)$$

$$CaO(s) + Al_2O_3(s) \xrightarrow{\Delta} Ca(AlO_2)_2(l)$$

$$6\,CaO(s) + P_4O_{10}(s) \xrightarrow{\Delta} 2\,Ca_3(PO_4)_2(l)$$

The mixture of products, which is known as *slag*, is molten at the temperatures in the furnace and floats on the denser molten iron. It is drawn off and used to make rocklike material for the construction industry.

Molten iron is produced through a series of reactions in the four main temperature zones of the furnace. At the bottom, in Zone A, preheated air is blown into the furnace under pressure, and the coke is oxidized to heat the furnace to 1900°C and provide carbon in the form of carbon dioxide. Higher up, the iron is reduced in stages to the metal, which melts and flows from Zone C to Zone A. Although the melting point of pure iron is 1540°C, iron mixed with 4% carbon melts at about 1015°C. As the carbon dioxide moves up through the furnace to Zone B, it reacts with some of the carbon provided by the coke, producing carbon monoxide. This reaction is endothermic and lowers the temperature to 1300°C. The carbon monoxide produced in this reaction rises to Zones C and D, where it reduces iron ore in a series of reactions, some of which are shown in Fig. 16.10. The iron runs out of the bottom of the furnace as molten pig iron, a high-carbon form of iron that must be further processed (see Section 6.3).

Iron is quite reactive and corrodes in moist air. It is passivated by oxidizing acids such as HNO_3 (Section 13.14) but reacts with nonoxidizing acids, evolving hydrogen and forming iron(II) salts. The colors of these salts vary from pale yellow to dark green-brown. Iron(II) salts are readily oxidized to iron(III) salts. The oxidation is slow in acidic solution but rapid in basic solution, where insoluble iron(III) hydroxide, $Fe(OH)_3$, is precipitated. Although $[Fe(OH_2)_6]^{3+}$ ions are pale purple and Fe^{3+} ions give amethyst

its purple color, the colors of aqueous solutions of iron(III) salts are dominated by the conjugate base of $[Fe(OH_2)_6]^{3+}$, the yellow $[FeOH(OH_2)_5]^{2+}$ ion:

$$[Fe(OH_2)_6]^{3+}(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + [FeOH(OH_2)_5]^{2+}(aq)$$

Like some other d-block metals, such as nickel, iron can form compounds in which its oxidation number is zero. For example, when iron is heated in carbon monoxide, it reacts to form *iron pentacarbonyl*, $Fe(CO)_5$, a yellow molecular liquid that boils at 103°C.

A healthy adult human body contains about 3 g of iron, mostly as hemoglobin. Because about 1 mg is lost daily (in sweat, feces, and hair), and women lose about 20 mg in each menstrual cycle, iron must be ingested daily to maintain the balance. Iron deficiency, or anemia, results in reduced transport of oxygen to the brain and muscles, and an early symptom is chronic tiredness.

Thinking point: Which common food sources provide iron in the diet?

Cobalt ores are often found in association with copper(II) sulfide. Cobalt is a silver-gray metal and is used mainly for alloying with iron. *Alnico steel*, an alloy of iron, nickel, cobalt, and aluminum, is used to make permanent magnets such as those in loudspeakers (see Section 6.4). Cobalt steels are hard enough to be used as surgical steels, drill bits, and lathe tools. The color of cobalt glass is due to a blue pigment that forms when cobalt(II) oxide is heated with silica and alumina.

Nickel, Ni, is also used in alloys. It is a hard, silver-white metal used mainly for the production of stainless steel (see Section 6.3) and for alloying with copper to produce *cupronickels*, the alloys used for nickel coins (which are about 25% Ni and 75% Cu). Nickel is also used in nicad batteries and as a catalyst, especially for the addition of hydrogen to organic compounds, as in the hydrogenation of vegetable oils (Section 18.6).

The slightly yellow hue of cupronickels is removed by the addition of small amounts of cobalt.

About 70% of the western world's supply of nickel comes from iron and nickel sulfide ores that were brought close to the surface nearly 2 billion years ago by the violent impact of a huge meteorite at Sudbury, Ontario. The ore is first *roasted* (heated in air) to form nickel(II) oxide, which is reduced to the metal either electrolytically or by reaction with hydrogen gas in the first step of the *Mond process*:

$$NiO(s) + H_2(g) \xrightarrow{\Delta} Ni(s) + H_2O(g)$$

The impure nickel is then refined by first exposing it to carbon monoxide, with which it forms nickel tetracarbonyl, $Ni(CO)_4$:

$$Ni(s) + 4\,CO(g) \longrightarrow Ni(CO)_4(g)$$

Nickel tetracarbonyl is a volatile, poisonous liquid that boils at 43°C and can therefore be removed from impurities. Nickel metal is then obtained by heating the pure nickel tetracarbonyl to about 200°C, at which temperature it decomposes.

Nickel's most common oxidation state is +2, and the green color of aqueous solutions of nickel salts is due to the presence of $[Ni(OH_2)_6]^{2+}$ ions.

The Period 4 d-block elements titanium through nickel are obtained chemically from their ores, with the ease of reduction increasing to the right in the periodic table. They have many industrial uses, particularly as alloys.

16.4 Groups 11 and 12

The elements close to the right-hand edge of the d-block have full d-orbitals. Group 11 contains the **coinage metals**—copper, silver, and gold—which have $(n-1)d^{10}ns^1$ valence electron configurations (Table 16.3). Group 12 contains zinc, cadmium, and mercury, with valence configurations $(n-1)d^{10}ns^2$. The low reactivity of the coinage metals is partly due to the poor shielding abilities of the d-electrons and hence the tight grip that the nucleus can exert on the outermost electron. This effect is enhanced in Period 6 by the lanthanide contraction, which helps to account for the inertness of gold.

TABLE 16.3 Properties of Elements in Groups 11 and 12

Z	Name	Symbol	Valence electron configuration	Melting point (°C)	Boiling point (°C)	Density, ($g\cdot cm^{-3}$)
29	copper	Cu	$3d^{10}4s^1$	1083	2567	8.93
47	silver	Ag	$4d^{10}5s^1$	962	2212	10.50
79	gold	Au	$5d^{10}6s^2$	1064	2807	19.28
30	zinc	Zn	$3d^{10}4s^2$	420	907	7.14
48	cadmium	Cd	$4d^{10}5s^2$	321	765	8.65
80	mercury	Hg	$5d^{10}6s^2$	−39	357	13.55

Copper, Cu, is unreactive enough for some to be found as the metal, but most is produced from its sulfides, particularly the ore *chalcopyrite*, $CuFeS_2$ (Fig. 16.11). The crushed and ground ore is separated from excess rock by *froth flotation*, a process that depends on the ability of sulfide ores to be wetted by oils but not by water. In this process, the powdered ore is combined with oil, water, and detergents (Fig. 16.12). Then air is blown through the mixture; the oil-coated sulfide mineral floats to the surface with the froth, and the unwanted copper-poor residue, which is called *gangue*, sinks to the bottom.

Processes for extracting metals from their ores are generally classified as **pyrometallurgical,** when high temperatures are used (Fig. 16.13), or **hydrometallurgical,** when aqueous solutions are used. Copper is extracted by both methods. In pyrometallurgical extraction, the enriched ore is roasted:

$$2\,CuFeS_2(s) + 3\,O_2(g) \xrightarrow{\Delta} 2\,CuS(s) + 2\,FeO(s) + 2\,SO_2(g)$$

The CuS is then *smelted*, a process in which metal ions are reduced by heating the molten ore with a reducing agent such as carbon (in the form of coke). At the same time, the sulfur is oxidized to SO_2 by blowing compressed air through the mixture of ore, limestone, and sand:

$$CuS(s) + O_2(g) \xrightarrow{\Delta} Cu(l) + SO_2(g)$$

The copper product is known as *blister copper* because of the appearance of air bubbles in the solidified metal. In the hydrometallurgical process, soluble Cu^{2+} ions are formed by the action of sulfuric acid on the ores. Then the metal is obtained by reducing these ions in aqueous solution either electrolytically or chemically, by using an inexpensive

FIGURE 16.11 Three important copper ores (from left to right): chalcopyrite, $CuFeS_2$; malachite, $CuCO_3\cdot Cu(OH)_2$; and chalcocite, Cu_2S.

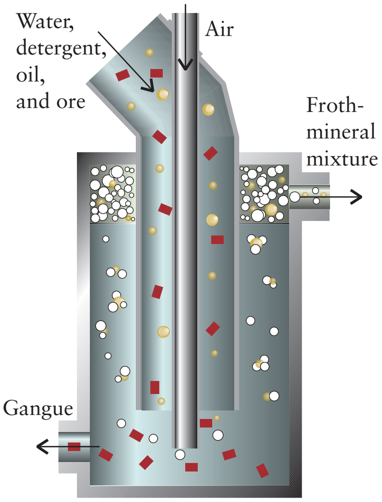

FIGURE 16.12 In the froth flotation process, a stream of bubbles (white circles) is passed through a mixture of ore (gold circles), rock (brown rectangles), and detergent. The ore is buoyed up by the froth of bubbles and is removed from the top of the chamber. The unwanted gangue is washed away through the bottom of the container.

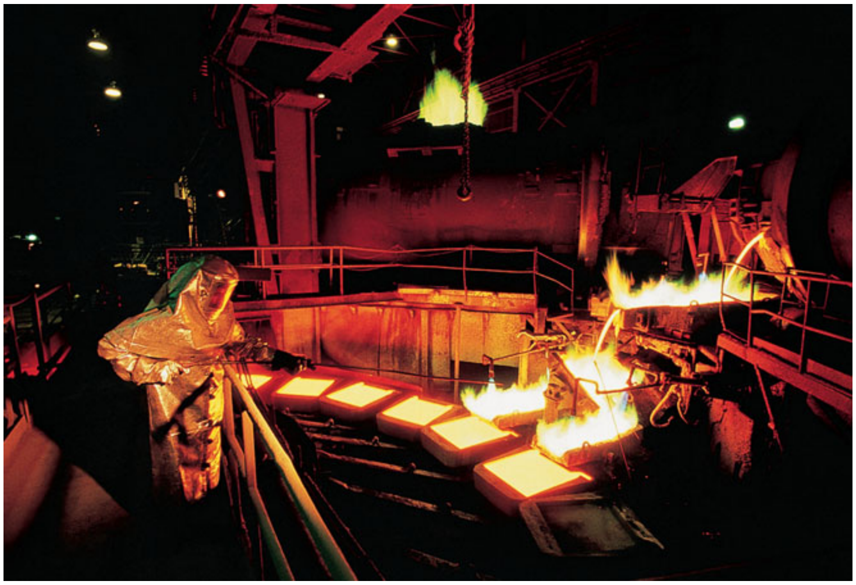

FIGURE 16.13 In this industrial-scale copper refinery, the molten impure copper produced by smelting is poured into molds. Next, the copper will be purified by electrolysis.

reducing agent that has a more negative standard potential than that of copper, such as hydrogen or iron (see Section 15.3):

$$Cu^{2+}(aq) + H_2(g) \longrightarrow Cu(s) + 2\,H^+(aq) \qquad \Delta G° = -65\text{ kJ}$$

The reduction is thermodynamically favored, because the standard potential of the couple Cu^{2+}/Cu is positive ($E° = +0.34$ V). Metals with negative standard potentials, such as zinc ($E° = -0.76$ V) and nickel ($E° = -0.23$ V), cannot be extracted hydrometallurgically.

The impure copper from either process is refined electrolytically: it is made into anodes and plated onto cathodes of pure copper. Other metals may be present in the impure copper and those with highly positive electrode potentials also are reduced. The rare metals—most notably, platinum, silver, and gold—obtained from the anode sludge are sold to recover much of the cost of the electricity used in the electrolysis.

Copper alloys such as brass and bronze, which are harder and more resistant to corrosion than is copper, are important construction materials (see Section 6.4). Copper corrodes in moist air in the presence of oxygen and carbon dioxide:

$$2\,Cu(s) + H_2O(l) + O_2(g) + CO_2(g) \longrightarrow Cu_2(OH)_2CO_3(s)$$

The pale green product is called *basic copper carbonate* and is responsible for the green patina of copper and bronze objects (Fig. 16.14). The patina adheres to the surface, protects the metal from further oxidation, and has a pleasing appearance.

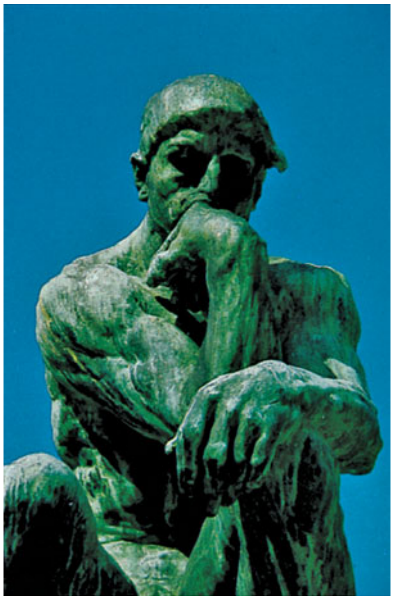

FIGURE 16.14 Copper corrodes in air to form an attractive pale green layer of basic copper carbonate. This patina, or incrustation, passivates the surface, which helps to protect it from further corrosion.

Like all the coinage metals, copper forms compounds with oxidation number +1. However, in water, copper(I) salts disproportionate into metallic copper and copper(II) ions. The latter exist as pale blue $[Cu(OH_2)_6]^{2+}$ ions in water.

Copper is essential in animal metabolism. In mammals, copper-bearing enzymes are necessary for healthy nerves and connective tissue. In some animals, such as the octopus and certain arthropods, it transports oxygen through the blood, a role performed by iron in mammals. As a result, the blood of these animals is green rather than red.

Silver, Ag, is rarely found as the metal. Most is obtained as a by-product of the refining of copper and lead, and a considerable amount is recycled through the photographic industry; however, that amount is diminishing due to the growth of digital photography. Silver has a positive standard potential, and so it does not reduce $H^+(aq)$ to hydrogen. Silver reacts readily with sulfur and sulfur compounds, producing the familiar black tarnish on silver dishes and cutlery.

Silver(I) does not disproportionate in aqueous solution; and, in almost all its compounds, silver has oxidation number +1. Apart from silver nitrate, $AgNO_3$, and silver fluoride, silver salts are generally only sparingly soluble in water. Silver nitrate is the most important compound of silver and the starting point for the manufacture of silver halides for use in photography.

Gold, Au, is so inert that most of it is found in nature as the metal. Pure gold is classified as 24-carat gold. Its alloys with silver and copper, which differ in hardness and hue, are classified according to the proportion of gold that they contain (Fig. 16.15). For example, 10- and 14-carat golds contain, respectively, $\frac{10}{24}$ and $\frac{14}{24}$ parts by mass of gold. Gold is a highly malleable metal, and 1 g of gold can be worked into a leaf covering an area of about 1 m^2 or pulled out into a wire more than 2 km long. Gold leaf provides a valuable decorative protection, such as that on dishes and books.

Gold is too noble to react even with strong oxidizing agents such as nitric acid. Both the gold couples

$$Au^{+}(aq) + e^{-} \longrightarrow Au(s) \qquad E° = +1.69\ V$$
$$Au^{3+}(aq) + 3\ e^{-} \longrightarrow Au(s) \qquad E° = +1.40\ V$$

lie above H^+/H_2 and $NO_3^-,H^+/NO,H_2O$:

$$NO_3^-(aq) + 4\ H^+(aq) + 3\ e^- \longrightarrow NO(g) + 2\ H_2O(l) \qquad E° = +0.96\ V$$

However, gold does react with *aqua regia*, a mixture of concentrated nitric and hydrochloric acids, because the complex ion $[AuCl_4]^-$ forms:

$$Au(s) + 6\ H^+(aq) + 3\ NO_3^-(aq) + 4\ Cl^-(aq) \longrightarrow [AuCl_4]^-(aq) + 3\ NO_2(g) + 3\ H_2O(l)$$

Despite the unfavorable equilibrium constant for the formation of Au^{3+} from gold, the reaction proceeds because any Au^{3+} ions formed are immediately complexed by Cl^- ions and removed from the equilibrium. In a process widely used in the refining of the metal, gold also reacts with sodium cyanide in an aerated aqueous solution to form the complex ion $[Au(CN)_2]^-$:

$$4\ Au(s) + 8\ NaCN(aq) + O_2(aq) + 2\ H_2O(l) \longrightarrow 4\ Na[Au(CN)_2](aq) + 4\ NaOH(aq)$$

Zinc, Zn, is found mainly as its sulfide, ZnS, in *sphalerite*, often in association with lead ores (see Fig. 15.42). The ore is concentrated by froth flotation, and the metal is extracted by roasting and then smelting with coke:

$$2\ ZnS(s) + 3\ O_2(g) \xrightarrow{\Delta} 2\ ZnO(s) + 2\ SO_2(g)$$

$$ZnO(s) + C(s) \xrightarrow{\Delta} Zn(l) + CO(g)$$

Zinc is used mainly for galvanizing iron; like copper, it is protected by a hard film of basic carbonate, $Zn_2(OH)_2CO_3$, which forms on contact with air.

Zinc and cadmium are both silvery, reactive metals that are similar to each other but differ sharply from mercury. Zinc is amphoteric (like its main-group neighbor aluminum). It reacts with acids to form Zn^{2+} ions and with alkalis to form the zincate ion, $[Zn(OH)_4]^{2-}$:

$$Zn(s) + 2\ OH^-(aq) + 2\ H_2O(l) \longrightarrow [Zn(OH)_4]^{2-}(aq) + H_2(g)$$

Galvanized containers should therefore not be used for transporting alkalis. Cadmium, which is lower down the group and is more metallic, has a more basic oxide.

Zinc and cadmium have an oxidation number of +2 in all their compounds. Zinc is an essential element for human health. It is present in many enzymes and plays a role in the expression of DNA and in growth. Zinc is toxic only in very high amounts. However, cadmium is a deadly poison that disrupts metabolism by substituting for other essential metals in the body such as zinc and calcium, leading to soft bones and to kidney and lung disorders.

Mercury, Hg, occurs mainly as HgS in the mineral *cinnabar* (see Fig. 15.42), from which it is separated by froth flotation and then roasting in air:

$$HgS(s) + O_2(g) \xrightarrow{\Delta} Hg(g) + SO_2(g)$$

The volatile metal is separated by distillation and condensed. Mercury is the only metallic element that is liquid at room temperature (gallium and cesium are liquids on

FIGURE 16.15 The color of commercial gold depends on its composition. Left to right: 8-carat gold, 14-carat gold, white gold, 18-carat gold, and 24-carat gold. White gold consists of 6 parts Au and 18 parts Ag by mass.

warm days). It has a long liquid range, from its melting point of −39°C to its boiling point of 357°C, and so it is well suited for its use in thermometers, silent electrical switches, and high-vacuum pumps.

Because mercury lies above hydrogen in the electrochemical series, it is not oxidized by hydrogen ions. However, it does react with nitric acid:

$$3\,Hg(l) + 8\,H^+(aq) + 2\,NO_3^-(aq) \longrightarrow 3\,Hg^{2+}(aq) + 2\,NO(g) + 4\,H_2O(l)$$

In nearly all its compounds, mercury has the oxidation number +1 or +2. Its compounds with oxidation number +1 are unusual in that the mercury(I) cation is the covalently bonded diatomic ion $(Hg–Hg)^{2+}$, written Hg_2^{2+}.

Compounds containing mercury, particularly its organic compounds, are acutely poisonous. Mercury vapor is an insidious poison because its effect is cumulative. Frequent exposure to low levels of mercury vapor can allow mercury to accumulate in the body. The effects include impaired neurological function, hearing loss, and other ailments.

Self-Test 16.2A Use standard Gibbs free energies of formation to calculate $\Delta G°$ at 298 K for the reaction $CuS(s) + O_2(g) \longrightarrow Cu(s) + SO_2(g)$. ($\Delta G_f°(CuS, s) = -49.0\ kJ\cdot mol^{-1}$.)

[***Answer:*** $\Delta G° = -251.2$ kJ]

Self-Test 16.2B Calculate $E_{cell}°$ for a cell powered by the reaction of mercury metal and nitric acid to form aqueous mercury(I) and gaseous NO.

Metals in Groups 11 and 12 are easily reduced from their compounds and have low reactivity as a result of poor shielding of the nuclear charge by the d-electrons. Copper is extracted from its ores by either pyrometallurgical or hydrometallurgical processes.

COORDINATION COMPOUNDS

Many of the d-block elements form characteristically colored solutions in water. For example, although solid copper(II) chloride is brown and copper(II) bromide is black, their aqueous solutions are both light blue. The blue color is due to the hydrated copper(II) ions, $[Cu(OH_2)_6]^{2+}$, that form when the solids dissolve. As the formula suggests, these hydrated ions have a specific composition; they also have definite shapes and properties. They can be regarded as the outcome of a reaction in which the water molecules act as Lewis bases (electron pair donors, Section 11.2) and the Cu^{2+} ion acts as a Lewis acid (an electron pair acceptor). This type of Lewis acid–base reaction is characteristic of many cations of d-block elements.

The formation of coordinate covalent bonds is described in Sections 2.11 and 11.2.

The hydrated ion $[Cu(OH_2)_6]^{2+}$ is an example of a **complex,** a species consisting of a central metal atom or ion to which a number of molecules or ions are attached by coordinate covalent bonds. A **coordination compound** is an electrically neutral compound in which at least one of the ions present is a complex. However, the terms *coordination compound* (the overall neutral compound) and *complex* (one or more of the ions or neutral species present in the compound) are often used interchangeably. Coordination compounds include complexes in which the central metal atom is electrically neutral, such as $Ni(CO)_4$, and ionic compounds, such as $K_4[Fe(CN)_6]$.

Much research focuses on the structures, properties, and uses of the complexes formed between d-metal ions acting as Lewis acids and a variety of Lewis bases, partly because they participate in many biological reactions. Hemoglobin and vitamin B_{12}, for example, are both complexes—the former of iron and the latter of cobalt (Box 16.1). Complexes of the d-metals are often brightly colored and magnetic and are used in chemistry for analysis, to dissolve ions (Section 12.13), in the electroplating of metals, and for catalysis. They are also the target of current research in solar-energy conversion, in atmospheric nitrogen fixation, and in pharmaceuticals.

16.5 Coordination Complexes

The name “ligand” comes from the Latin word meaning “to bind.”

The Lewis bases attached to the central metal atom or ion in a d-metal complex are known as **ligands;** they can be either ions or molecules. An example of an ionic ligand

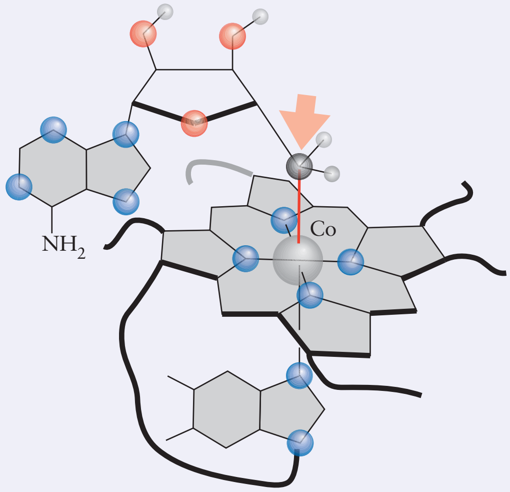
BOX 16.1 WHAT HAS THIS TO DO WITH . . . STAYING ALIVE?

Why We Need to Eat d-Metals

Some of the critical enzymes in our cells are *metalloproteins*, large organic molecules made up of folded polymerized chains of amino acids that also include at least one metal atom. These metalloproteins are intensely studied by biochemists, because they control life and protect against disease. They have also been used to trace evolutionary paths. The d-block metals catalyze redox reactions, form components of membrane, muscle, skin, and bone, catalyze acid–base reactions, control the flow of energy and oxygen, and carry out nitrogen fixation.

Hemoglobin, in which an iron atom lies as iron(II) at the center of a heme group, is the most familiar metalloprotein. Four nitrogen atoms from amine groups in the heme serve as the ligands in a square planar arrangement. The oxygen molecule serves as a fifth ligand, attaching itself directly to the iron atom and producing a modified square pyramidal shape about the iron atom. Carbon monoxide forms a much stronger bond to the iron atom than oxygen does—hence its high toxicity: the attached CO ligand prevents an O_2 molecule from attaching to the iron, and the victim suffocates.

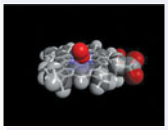
Cobalt is a d-metal needed to prevent pernicious anemia and some kinds of mental illness. It is an essential part of a coenzyme required for the activity of vitamin B_{12} (which is also called cobalamin) and gives the vitamin its red color. The cobalt atom is found in an octahedral complex in which five of the ligands are attached through nitrogen atoms from organic amine groups and one ligand attaches through a $—CH_2—$ group. Cobalamin is the only biomolecule known to have a metal–carbon bond. The ease with which this bond is broken and the ability of the cobalt ion to change from one oxidation state to another are responsible for the importance of cobalamin as a biological catalyst.

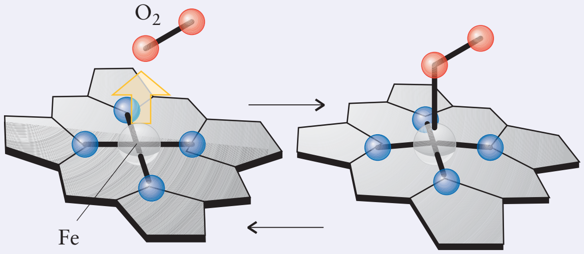


In cobalamin, vitamin B_{12}, one of the six ligands forming an octahedral structure around a cobalt atom is an organic molecule attached through a carbon–cobalt bond (red). The bond is weak and easily broken.

Zinc enzymes play several important roles in metabolism, including the expression of our genes, the digestion of food, the storage of insulin, and the building of collagen. In fact, zinc has so many functions in our systems that it has been called a "master hormone." Its concentration in our bodies is about the same as that of iron, but the intracellular concentration of zinc declines with aging. It has even been suggested that aging is actually a result of the decline in intracellular zinc concentration. However, this decline cannot be slowed by eating more zinc; intracellular zinc concentrations are controlled by enzymes, not by the lack of zinc in the diet.

Other d-metals are also vital to health. For example, chromium(III) plays a role in the regulation of glucose metabolism. Copper(I) is an essential nutrient for healthy cells and is the only biologically available Lewis acid with a +1 charge.





Molecular oxygen is transported throughout the body by attaching to the iron(II) atom in the heme group of hemoglobin. The iron(II) atom lies at the center of a square planar complex formed by nitrogen atoms. When the O_2 molecule attaches to the iron, the plane of the heme group becomes distorted.

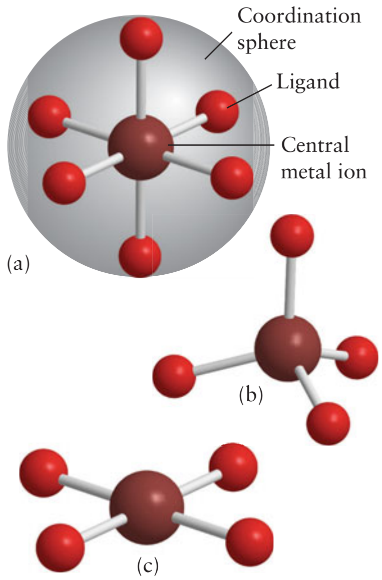

FIGURE 16.16 (a) Almost all six-coordinate complexes are octahedral. Four-coordinate complexes are either (b) tetrahedral or (c) square planar.

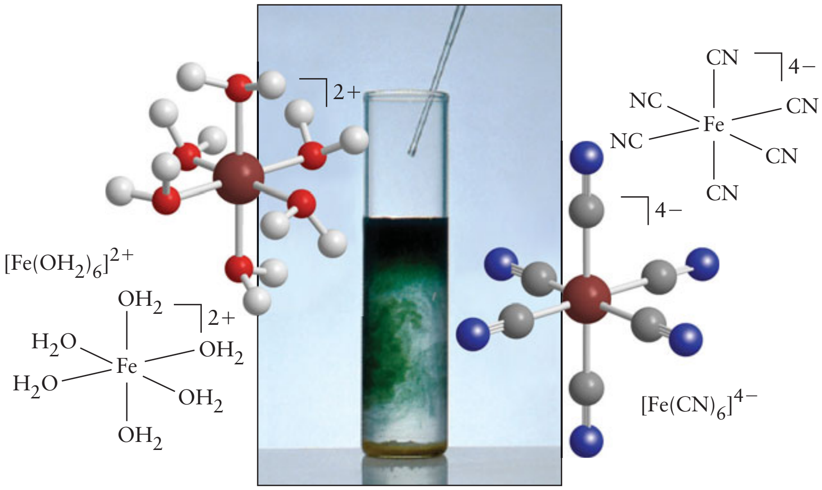

FIGURE 16.17 When potassium cyanide is added to a solution of iron(II) sulfate, the cyanide ions replace the H_2O ligands of the $[Fe(OH_2)_6]^{2+}$ complex (left) and produce a new complex, the hexacyanoferrate(II) ion, $[Fe(CN)_6]^{4-}$ (right). The blue color is due to the polymeric compound called *Prussian blue,* which forms from the cyanoferrate ion.

is the cyanide ion. In the hexacyanoferrate(II) ion, $[Fe(CN)_6]^{4-}$, the CN^- ions provide the electron pairs that form bonds to the Lewis acid Fe^{2+}. In the neutral complex $Ni(CO)_4$, the Ni atom acts as the Lewis acid and the ligands are the CO molecules.

Each ligand in a complex typically has at least one lone pair of electrons with which it bonds to the central atom or ion by forming a coordinate covalent bond. We say that the ligands **coordinate** to the metal when they form the complex in this way. In the chemical formula for a complex, we usually represent the ligands directly attached to the central ion by enclosing them and the central ion within rectangular brackets (the exceptions are neutral complexes). These ligands make up the **coordination sphere** of the central ion. The number of points at which ligands are attached to the central metal atom is called the **coordination number** of the complex (Fig. 16.16). The coordination number is 4 in $Ni(CO)_4$ and 6 in $[Fe(CN)_6]^{4-}$.

Because water is a Lewis base, it forms complexes with most d-block ions when they dissolve in it. Aqueous solutions of d-metal ions are usually solutions of their H_2O complexes: $Fe^{2+}(aq)$, for instance, is more accurately $[Fe(OH_2)_6]^{2+}$. Many complexes are prepared simply by mixing aqueous solutions of a d-metal ion with the appropriate Lewis base (Fig. 16.17); for example,

$$[Fe(OH_2)_6]^{2+}(aq) + 6\,CN^-(aq) \longrightarrow [Fe(CN)_6]^{4-}(aq) + 6\,H_2O(l)$$

This is an example of a **substitution reaction,** a reaction in which one Lewis base takes the place of another. Here the CN^- ions drive out H_2O molecules from the coordination sphere of the $[Fe(OH_2)_6]^{2+}$ complex and take their place. Replacement is less complete when certain other ions, such as Cl^-, are added to an iron(II) solution:

$$[Fe(OH_2)_6]^{2+}(aq) + Cl^-(aq) \longrightarrow [FeCl(OH_2)_5]^{+}(aq) + H_2O(l)$$

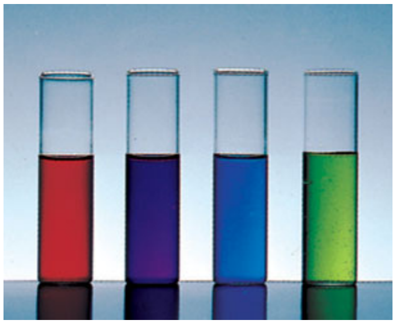

FIGURE 16.18 Some of the highly colored d-metal complexes. Left to right: aqueous solutions of $[Fe(SCN)(OH_2)_5]^{2+}$, $[Co(SCN)_4(OH_2)_2]^{2-}$, $[Cu(NH_3)_4(OH_2)_2]^{2+}$, and $[CuBr_4]^{2-}$.

Because the color of a d-metal complex depends on the identity of the ligands as well as that of the metal, impressive changes in color often accompany substitution reactions (Fig. 16.18).

The names of coordination compounds can become awesomely long because the identity and number of each type of ligand must be included. In most cases, chemists avoid the problem by using the chemical formula rather than the name itself. For instance, it is much easier to refer to $[FeCl(OH_2)_5]^{+}$ than to pentaaquachloridoiron(II) ion, its formal name. However, names are sometimes needed, and they can be constructed and interpreted, in simple cases at least, by using the rules set out in Toolbox 16.1. Table 16.4 gives the names of common ligands and their abbreviations, which are used

Further information on naming complexes can be found at http://old.iupac.org/publications/books/seriestitles/nomenclature.html; refer to the "Red Book."

in the formulas of complexes. The rules have recently been changed, but as the older names are still in wide use, we give both.

TOOLBOX 16.1 HOW TO NAME d-METAL COMPLEXES AND COORDINATION COMPOUNDS

CONCEPTUAL BASIS

The aim of nomenclature is to be succinct but unambiguous. d-Metal complexes are identified by giving the names and numbers of the individual ligands. Because some names can be quite long, interpreting them is rather like eating a large bun: nibble it bite by bite, don't try to swallow it in one gulp. The rules undergo periodic change in order to achieve greater clarity and consistency. The rules used here are consistent with the latest (2005) IUPAC recommendations.

PROCEDURE

The following rules are adequate for most common complexes; more elaborate rules are needed if the complex contains more than one metal atom. Note that some rules apply to naming the complex (formally, the "coordination entity") and others to writing its chemical formula.

A. Writing the formula

1. The chemical symbol of the central atom (usually a metal) is written first, followed by symbols for the ligands. The entire collection of symbols is placed between square brackets, with the overall charge denoted by a right-superscript.
2. The chemical symbols of ligands are written in alphabetical order; when different ligands contain the same element, those denoted by a single letter (e.g., O) take precedence over symbols represented by two or more letters (e.g., OH). If a particular point needs to be emphasized, then the order may be varied. Water as a ligand is denoted OH_2 to emphasize that the O links to the metal atom.

   Examples: $[FeCl(OH_2)_5]^+$ $[Fe(NH_3)_5(OH_2)]^{3+}$

3. To avoid any ambiguity, the linking atom can be underlined.

   Examples: $[Fe(\underline{N}CS)(OH_2)_5]^{2+}$ $[Fe(NC\underline{S})(OH_2)_5]^{2+}$

B. Naming the complex

1. Name the ligands first and then the metal atom or ion. A Roman numeral denotes the oxidation number of the central metal ion.
2. Neutral ligands, such as $H_2NCH_2CH_2NH_2$ (ethylenediamine), have the same name as the molecule, except for H_2O (aqua), NH_3 (ammine), CO (carbonyl), and NO (nitrosyl).
3. Anionic ligands end in -o; for anions that end in -ide (such as chloride), -ate (such as sulfate), and -ite (such as nitrite), change the endings as follows:

   -ide ⟶ -ido -ate ⟶ -ato -ite ⟶ -ito

   Examples: chlorido, sulfato, and nitrito.

4. Greek prefixes indicate the number of each type of ligand in the complex ion:

2	3	4	5	6	...
di-	tri-	tetra-	penta-	hexa-	...

   If the ligand already contains a Greek prefix (as in ethylenediamine) or if it is polydentate (able to attach at more than one binding site), then the following prefixes are used instead:

2	3	4	...
bis-	tris-	tetrakis-	...

5. Ligands are named in alphabetical order, ignoring the Greek prefix that indicates the number of each one present.

   $[FeCl(OH_2)_5]^+$ pentaaquachloridoiron(II) ion
   $[Cr(Cl)_2(NH_3)_4]^+$ tetraamminedichloridochromium(III) ion

   (Note that in some cases the order of ligands in the name is not the same as the order in the formula.)

6. If there is an ambiguity in which atom is liked to the metal atom, then κ*E* is added to the name in parentheses, where *E* denotes the connecting atoms (and κ is kappa):

   $[Fe(\underline{N}CS)(OH_2)_5]^{2+}$ thiocyanato(κ*N*)pentaaqua(III) iron
   $[Fe(NC\underline{S})(OH_2)_5]^{2+}$ thiocyanato(κ*S*)pentaaqua(III) iron

7. If the complex has an overall negative charge (an anionic complex), the suffix -ate is added to the stem of the metal's name. If the symbol of the metal originates from a Latin name (as listed in Appendix 2D), then the Latin stem is used. For example, the symbol for iron is Fe, from the Latin *ferrum*. Therefore, any anionic complex of iron ends with -ferrate followed by the oxidation number of the metal in Roman numerals:

   $[Fe(CN)_6]^{4-}$ hexacyanidoferrate(II) ion
   $[Ni(CN)_4]^{2-}$ tetracyanidonickelate(II) ion

8. The name of a coordination compound (as distinct from a complex cation or anion) is built in the same way as that of a simple compound, with the cation named before the anion:

   $NH_4[PtCl_3(NH_3)]$
   ammonium amminetrichloridoplatinate(II)
   $[Cr(NH_3)_4(OH)_2]Br$
   tetraamminedihydroxidochromium(III) bromide

This procedure is illustrated in Example 16.1.

EXAMPLE 16.1 Naming complexes and coordination compounds

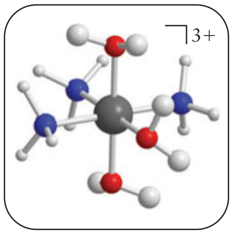
(a) Name the coordination compound $[Co(NH_3)_3(OH_2)_3]_2(SO_4)_3$. (b) Write the formula of sodium dichloridobis(oxalato)platinate(IV).

PLAN Apply the rules in Toolbox 16.1.

SOLVE

(a) There are three SO_4^{2-} ions for every two complex ions.

The complex cation must have a charge of +3: $[Co(NH_3)_3(OH_2)_3]^{3+}$.



All the ligands are neutral.

Co is present as cobalt(III).

There are three NH_3 molecules (ammine) and three H_2O molecules (aqua); ammine precedes aqua alphabetically.

The cation is triamminetriaquacobalt(III), and the compound is triamminetriaquacobalt(III) sulfate.

(b) Two Cl^- ligands and two $C_2O_4^{2-}$ ions are attached to Pt^{4+}.

The charge on the complex is −2.

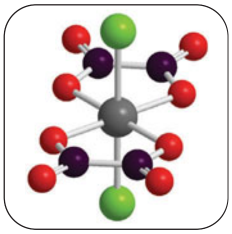


TABLE 16.4 Common Ligands

Formula*	Name
Neutral ligands	
OH_2	aqua
NH_3	ammine
NO	nitrosyl
CO	carbonyl
$NH_2CH_2CH_2NH_2$	ethylenediamine (en)†
$NH_2CH_2CH_2NHCH_2CH_2NH_2$	diethylenetriamine (dien)‡
Anionic ligands	
F^-	fluorido
Cl^-	chlorido
Br^-	bromido
I^-	iodido
OH^-	hydroxido
O^{2-}	oxido
$\underline{C}N^-$	cyanido-κ*C*
$C\underline{N}^-$	isocyanido, cyanido-κ*N*
$\underline{N}CS^-$	thiocyanato-κ*N*
$NC\underline{S}^-$	isothiocyanato, thiocyanato-κ*S*
NO_2^- as $\underline{O}NO^-$	nitrito-κ*O*
NO_2^- as $\underline{N}O_2^-$	nitro, nitrito-κ*N*
CO_3^{2-} as $\underline{O}CO_2^{2-}$	carbonato-κ*O*
$C_2O_4^{2-}$ as $^-O_2CCO_2^-$	oxalato (ox)†
	ethylenediaminetetraacetato (edta)§
SO_4^{2-} as OSO_3^{2-}	sulfato

*Ligand atoms that bond to the metal atom are in underlined in ambiquous cases.
†Bidentate (attaches to two sites).
‡Tridentate (attaches to three sites).
§Hexadentate (attaches to six sites).

From Table 16.4, the symbol for oxalate is ox; Cl precedes ox alphabetically; the use of "bis" indicates that two oxalato ligands are present; "bis" is used instead of "di" because oxalate is polydentate (in this case, bidentate, with two points of connection).

The complex anion is $[PtCl_2(ox)_2]^{2-}$.

The compound is $Na_2[PtCl_2(ox)_2]$.

Self-Test 16.3A (a) Name the compound $[Fe(OH)(OH_2)_5]Cl_2$. (b) Write the formula of potassium diaquabis(oxalato)chromate(II).

[*Answer:* (a) Pentaaquahydroxidoiron(III) chloride; (b) $K_2[Cr(OH_2)_2(ox)_2]$]

Self-Test 16.3B (a) Name the compound $[CoBr(NH_3)_5]SO_4$. (b) Write the formula of tetraamminediaquachromium(III) bromide.

A complex is formed between a Lewis acid (the metal atom or ion) and a number of Lewis bases (the ligands).

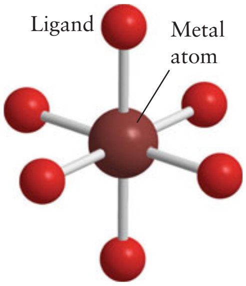
16.6 The Shapes of Complexes

The richness of coordination chemistry is enhanced by the variety of shapes that complexes can adopt. The most common complexes have coordination number 6. Almost all these species have their ligands at the vertices of a regular octahedron, with the metal ion at the center, and are called **octahedral complexes** (**1**). An example of an octahedral complex is the hexacyanidoferrate(II) ion, $[Fe(CN)_6]^{4-}$.

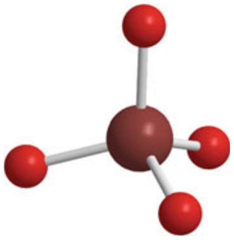
The next most common coordination number is 4. Two shapes are typically found for this coordination number. In a **tetrahedral complex,** the four ligands are found at the vertices of a tetrahedron, as in the tetrachloridocobaltate(II) ion, $[CoCl_4]^{2-}$ (**2**). An alternative arrangement, most notably for atoms and ions with d^8 electron configurations such as Pt^{2+} and Au^{3+}, is for the ligands to lie at the corners of a square, giving a **square-planar complex** (**3**).

Many other shapes are possible for complexes. The simplest are linear, with coordination number 2. An example is dimethylmercury(0), $Hg(CH_3)_2$ (**4**), which is a toxic compound formed by bacterial action on aqueous solutions of Hg^{2+} ions. Coordination numbers as high as 12 are found for members of the f-block, but they are rare in the d-block. One interesting type of d-metal compound in which there are 10 links between the ligands and the central metal ion is ferrocene, dicyclopentadienyliron(0), $[Fe(C_5H_5)_2]$ (**5**). Ferrocene is an aptly named "sandwich compound," with the two planar cyclopentadienyl ligands the "bread" and the metal atom the "filling." The formal name for a sandwich compound is a **metallocene.**

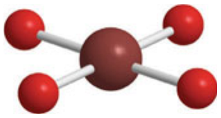
Complexes of molybdenum and tungsten with eight ligands are known. These complexes have antiprismatic (**6**) or dodecahedral shapes (**7**). However, complexes with more than six ligands are rare.



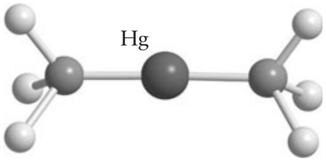
1 An octahedral complex



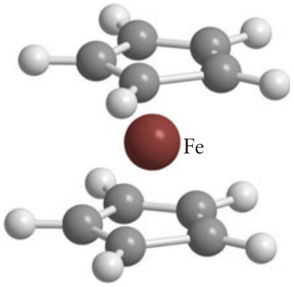
2 A tetrahedral complex



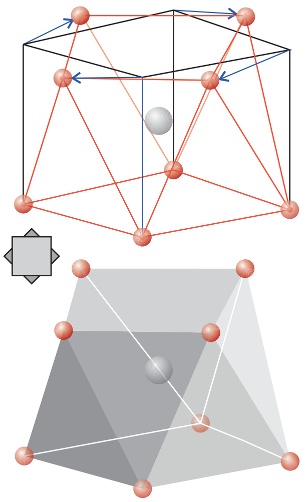
3 A square-planar complex



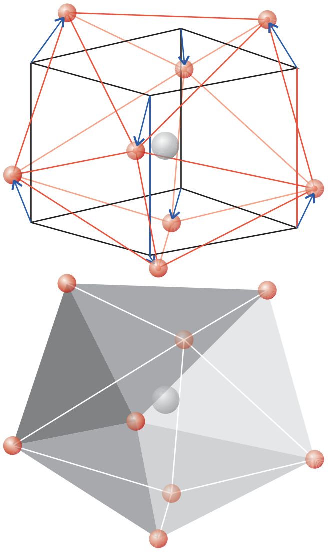
4 Dimethylmercury(0)



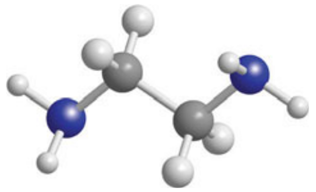
5 Ferrocene, $Fe(C_5H_5)_2$



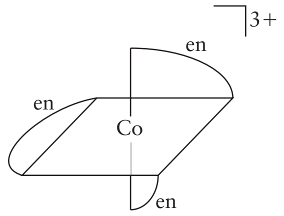
6 Square antiprism



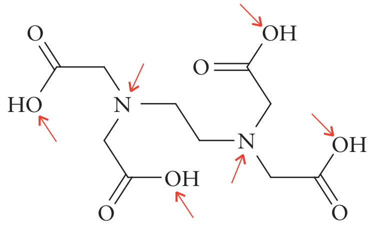
7 Dodecahedral complex



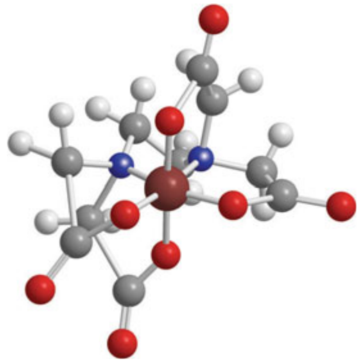
8 Ethylenediamine, $NH_2CH_2CH_2NH_2$



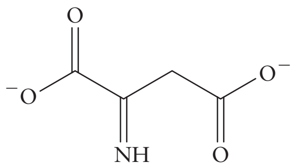
9 $[Co(en)_3]^{3+}$



10 Ethylenediaminetetraacetic acid



11 An edta complex



12 Iminodisuccinate ion

Isomerism is very important in organic chemistry, and the topic is developed again in Section 18.2.

Some ligands are **polydentate** ("many toothed") and can occupy more than one binding site simultaneously. For example, each end of the *bidentate* (that is, two-toothed) ethylenediamine molecule, $NH_2CH_2CH_2NH_2$ (**8**), has a nitrogen atom with a lone pair of electrons. This ligand is widely used in coordination chemistry and is abbreviated to en, as in tris(ethylenediamine)cobalt(III), $[Co(en)_3]^{3+}$ (**9**). The metal ion in $[Co(en)_3]^{3+}$ lies at the center of the three ligands as though pinched by three molecular claws. It is an example of a **chelate** (from the Greek word for "claw"), a complex containing one or more ligands that form a ring of atoms that includes the central metal atom. There are few hexadentate ligands, but a common example is the ethylenediaminetetraacetate ion, edta (the fully protonated acid is shown as **10**; the red arrows show the points of attachment). This ligand forms complexes with many metal ions, including Pb^{2+} (**11**); hence, it is used as an antidote to lead poisoning.

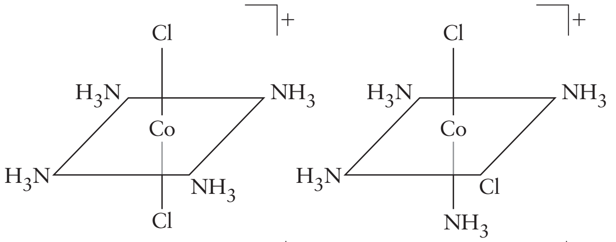
The production of some chelates releases toxic chemicals such as cyanides to the environment. However, new types of chelates that **sequester** d-block metals, bind with them, and remove them from solution, may provide solutions to some of society's trickiest environmental problems. For example, the chelating agent sodium iminodisuccinate, which contains the hexadentate iminodisuccinate ion (**12**), can scavenge metal ions from solutions used to develop photographs and from drinking water and serves as a nontoxic additive to detergents. It is rapidly degraded to nontoxic products in the environment. Other environmentally friendly chelates accelerate the action of hydrogen peroxide and the combination is replacing chlorine bleaches in the production of paper, greatly reducing the release of toxic pollutants to the environment.

Chelating ligands are quite common in nature. Mosses and lichens secrete chelating ligands to extract essential metal ions from the rocks on which they dwell. Chelate formation also lies behind the body's strategy of producing a fever when infected by bacteria. The higher temperature kills bacteria by reducing their ability to synthesize a particular iron-chelating ligand.

Complexes with coordination number 6 tend to be octahedral; those with coordination number 4 are either tetrahedral or square planar. Polydentate ligands can form chelates.

16.7 Isomers

Many complexes and coordination compounds exist as **isomers,** compounds that contain the same numbers of the same atoms but in different arrangements. For example, the ions shown in (**13a**) and (**13b**) differ only in the positions of the Cl^- ligands, but they are distinct species, because they have different physical and chemical properties. Isomerism is of more than academic interest: for example, anticancer drugs based on complexes of platinum are active only if they are the correct isomer. The complex needs to have a particular shape to interact with DNA molecules.



(a) *trans*-$[CoCl_2(NH_3)_4]^+$ (b) *cis*-$[CoCl_2(NH_3)_4]^+$

13

Figure 16.19 summarizes the types of isomerism found in coordination complexes. The two major classes of isomers are **structural isomers,** in which the atoms are connected to different partners, and **stereoisomers,** in which the atoms have the same partners but are arranged differently in space. Structural isomers of coordination compounds are subdivided into ionization, hydrate, linkage, and coordination isomers.

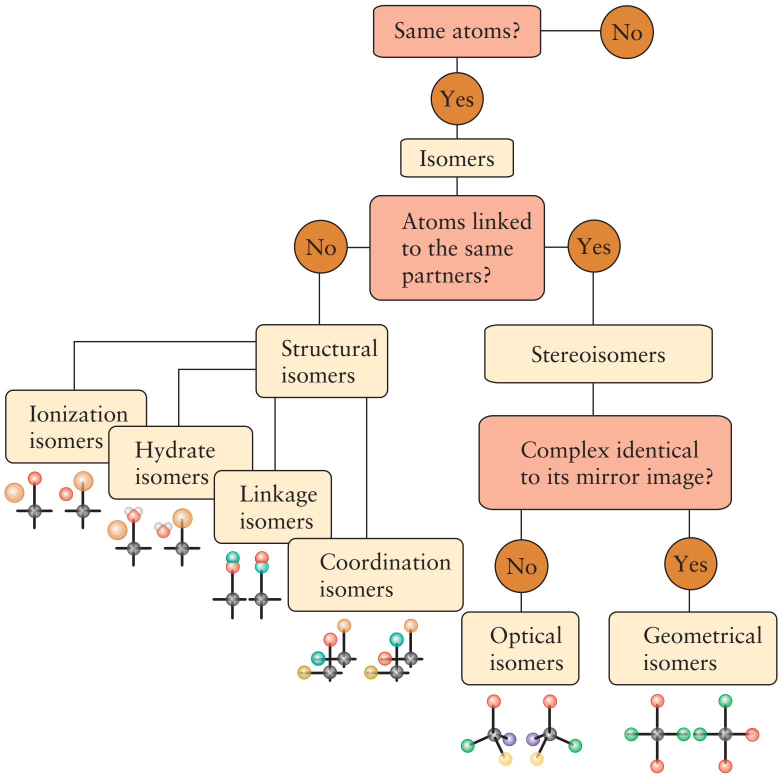


FIGURE 16.19 The various types of isomerism in coordination compounds.

Ionization isomers differ by the exchange of a ligand with an anion or a neutral molecule outside the coordination sphere. For instance, $[CoBr(NH_3)_5]SO_4$ and $[Co(NH_3)_5SO_4]Br$ are ionization isomers because the Br^- ion is a ligand of the cobalt in the former but an accompanying anion in the latter. The isomers can be distinguished by their chemical properties, because an ion inside the complex is not available for reaction. Thus, the addition of a barium salt will result in the precipitation of barium sulfate from a solution of $[CoBr(NH_3)_5]SO_4$, but not from a solution of $[Co(NH_3)_5SO_4]Br$.

Hydrate isomers differ by the exchange of an H_2O molecule with another ligand in the coordination sphere (Fig. 16.20). For example, the solid hexahydrate of chromium(III) chloride, $CrCl_3{\cdot}6H_2O$, may also be any of the three compounds $[Cr(OH_2)_6]Cl_3$, $[CrCl(OH_2)_5]Cl_2{\cdot}H_2O$, or $[CrCl_2(OH_2)_4]Cl{\cdot}2H_2O$. Hydrate isomers can often be distinguished by the stoichiometry of reactions in which the ion is exchanged with water. For example, 2 mol AgCl can be precipitated from 1 mol $[CrCl(OH_2)_5]Cl_2{\cdot}H_2O$, but only 1 mol AgCl can be produced from 1 mol $[CrCl_2(OH_2)_4]Cl{\cdot}2H_2O$.

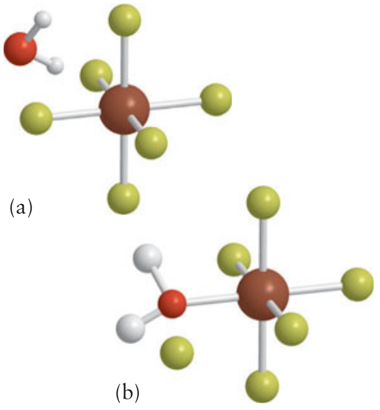

FIGURE 16.20 Hydrate isomers. In part (a), the water molecule is simply part of the surrounding solvent; in part (b), the water molecule is present in the coordination sphere and a ligand (green sphere) is now present in the solution.

Self-Test 16.4A When excess silver nitrate is added to 0.0010 mol $CrCl_3{\cdot}6H_2O$ in aqueous solution, 0.0010 mol AgCl is formed. Which hydrate isomer is present?

[***Answer:*** $[CrCl_2(OH_2)_4]Cl{\cdot}2H_2O$]

Self-Test 16.4B When excess silver nitrate is added to 0.0010 mol $CrCl_3{\cdot}6H_2O$ in aqueous solution, 0.0030 mol AgCl is formed. Which hydrate isomer is present?

Linkage isomers differ in the identity of the atom used by a given ligand to attach to the metal ion (Fig. 16.21). Common ligands that show linkage isomerism are SCN^- versus NCS^-, NO_2^- versus ONO^-, and CN^- versus NC^-, where the coordinating atom is written first in each pair. For example, NO_2^- can form $[CoCl(NH_3)_4(NO_2)]^+$ and $[CoCl(NH_3)_4(ONO)]^+$. In the new system of nomenclature, the atom through which the ligand is coordinated is underlined, so these two complexes would be denoted $[CoCl(NH_3)_4(\underline{N}O_2)]^+$ and $[CoCl(NH_3)_4(N\underline{O}_2)]^+$, respectively. The name used to specify the ligand is different in each case. For instance, nitro (modern name: nitrito-(κ*N*) signifies that the ligand is linked through the N atom and nitrito (modern name: nitrito-κ*O*) that it is linked through an O atom. Table 16.4 lists the names to use for these so-called **ambidentate ligands** that can attach through atoms of different elements.

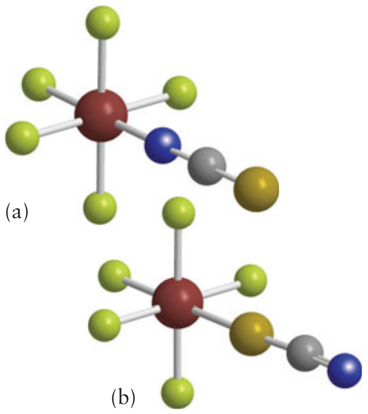

FIGURE 16.21 Linkage isomers. In part (a), the ligand (here NCS^-) is attached through its N atom; but in part (b), it is attached through its S atom.

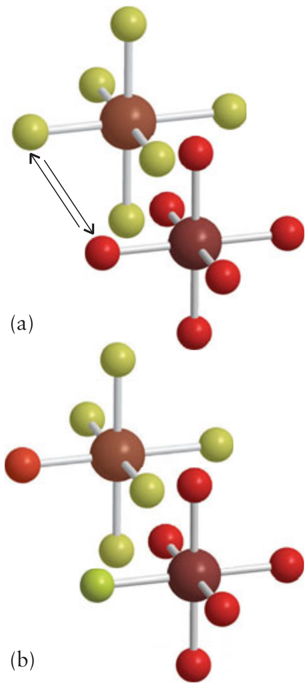

FIGURE 16.22 The compounds in parts (a) and (b) are coordination isomers. In these compounds, a ligand has been exchanged between the cationic and anionic complexes.

Coordination isomers differ by the exchange of one or more ligands between a cationic complex and an anionic complex (Fig. 16.22). Thus, $[Cr(NH_3)_6][Fe(CN)_6]$ and $[Fe(NH_3)_6][Cr(CN)_6]$ are coordination isomers.

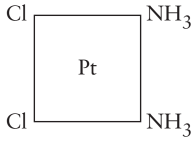
Self-Test 16.5A Identify the type of isomer represented by each of the following pairs: (a) $[Cu(NH_3)_4][PtCl_4]$ and $[Pt(NH_3)_4][CuCl_4]$; (b) $[Cr(OH)_2(NH_3)_4]Br$ and $[CrBr(OH)(NH_3)_4]OH$.

[***Answer:*** (a) Coordination; (b) ionization]

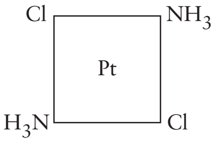
Self-Test 16.5B Identify the type of isomer represented by each of the following pairs: (a) $[Co(\underline{N}CS)(NH_3)_5]Cl_2$ and $[Co(NC\underline{S})(NH_3)_5]Cl_2$; (b) $[CrCl(OH_2)_5]Cl_2{\cdot}H_2O$ and $[CrCl_2(OH_2)_4]Cl{\cdot}2H_2O$.

Although they are built from the same numbers and kinds of atoms, *structural isomers* have different chemical formulas, because the formulas show how the atoms are grouped in or outside the coordination sphere. *Stereoisomers*, on the other hand, have the same formulas, because their atoms have the same partners in the coordination spheres; only the spatial arrangement of the ligands differs. There are two types of stereoisomerism, geometrical and optical.

In **geometrical isomers,** atoms are bonded to the same neighbors but have different locations relative to each other, as in (**13a**) and (**13b**): the complex with the Cl^- ligands on opposite sides of the central atom is called the *trans isomer,* and the complex with the ligands on the same side is called the *cis isomer.* Geometrical isomers can occur for square planar and octahedral complexes but not for tetrahedral complexes, because in the latter any pair of vertices is equivalent to any other pair. The chemical and physiological properties of geometrical isomers can differ greatly. For example, *cis*-$[PtCl_2(NH_3)_2]$ (**14a**) is used for chemotherapy treatment of cancer patients, but *trans*-$[PtCl_2(NH_3)_2]$ (**14b**) is therapeutically inactive. **Optical isomers** are nonsuperimposable mirror images of each other (Fig. 16.23). Both geometrical and optical isomerism can occur in an octahedral complex, as in $[CoCl_2(en)_2]^+$: the trans isomer (**15a**) is green, and the two alternative cis isomers (**15b**) and (**15c**), which are optical isomers of one another, are violet. Optical isomers can also occur whenever four different groups form a tetrahedral complex, but not if they form a square planar complex.

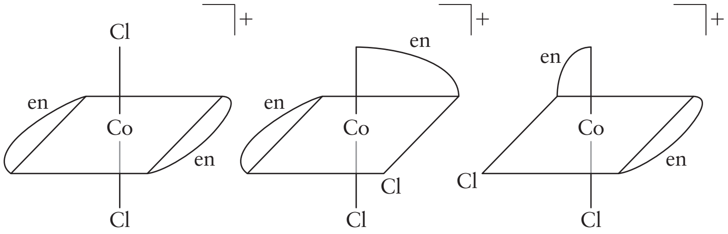


(a) *cis*-$[PtCl_2(NH_3)_2]$



(b) *trans*-$[PtCl_2(NH_3)_2]$

14



(a) *trans*-$[CoCl_2(en)_2]^+$ (b) *cis*-$[CoCl_2(en)_2]^+$ (c) *cis*-$[CoCl_2(en)_2]^+$

15

The name *enantiomer* comes from the Greek words meaning "both parts."

A **chiral complex** is one that is not identical to its mirror image. Thus, all optical isomers are chiral. The cis isomers of $[CoCl_2(en)_2]^+$ are chiral, and a chiral complex and its mirror image form a pair of **enantiomers.** The trans isomer is superimposable on its mirror image; complexes with this property are called **achiral.** Enantiomers differ in one physical property: chiral molecules display **optical activity,** the ability to rotate the plane of polarization of light (Box 16.2). In ordinary light, the plane of wave motion lies at random orientations around the direction of travel. In plane-polarized

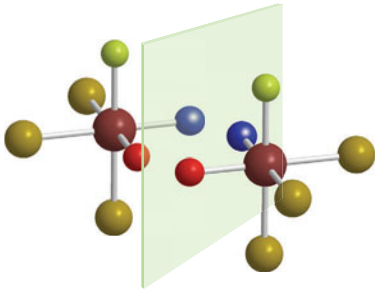


FIGURE 16.23 Optical isomers. The two complexes are each other's mirror image; no matter how we rotate them, one complex cannot be superimposed on the other.

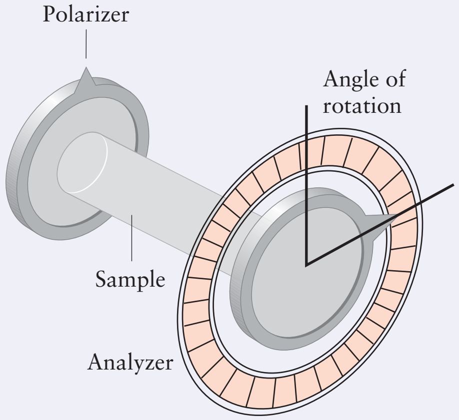
BOX 16.2 HOW DO WE KNOW . . . THAT A COMPLEX IS OPTICALLY ACTIVE?

The electric field of plane-polarized light oscillates in a single plane. It can be prepared by passing ordinary, unpolarized light through a polarizer, which contains a material that allows the light to pass only if the electric field is aligned in a certain direction.

An optically active substance, such as a chiral complex, rotates the plane of polarization of a beam of light by an angle that depends on the substance, its concentration, and the length of the sample cell. The light is passed through a sample cell about 10 cm long. To detect chirality, a solution of the chiral complex is placed in the cell. When the light emerges from the far end of the cell, the angle of its plane of polarization may have rotated from its original angle. To determine the angle, the light is passed through an analyzer that contains another polarizing filter. The filter is rotated until the intensity of the light that has passed through the polarizer, sample, and filter reaches its maximum. The angle of the plane of polarization is determined from the angle through which the filter was rotated to achieve this maximum setting. If the sample is not optically active, the light is not rotated by the sample and the maximum intensity is observed at an angle of 0°. The sample is optically active if the angle of rotation is different from 0°. The actual value depends on the identity of the complex, its concentration, the wavelength of the light, and the length of the sample cell.



A polarimeter is used to determine the optical activity of a substance by measuring the angle through which plane-polarized light is rotated by a sample.

The determination of the angle of rotation is called *polarimetry*. In some cases, it can help a chemist follow a reaction. For example, if a reaction destroys the chirality of a complex, then the angle of optical rotation decreases with time as the concentration of the complex falls.

light, the wave lies in a single plane (Fig. 16.24). Plane-polarized light can be prepared by passing ordinary light through a special filter, such as the material used to make polarized sunglasses. One enantiomer of a chiral complex rotates the plane of polarization clockwise; its mirror-image partner rotates it by the same amount the other way. Achiral complexes are not optically active: they do not rotate the plane of polarization of polarized light.

Some complexes are synthesized in the laboratory as **racemic mixtures,** or mixtures of enantiomers in equal proportions. Because enantiomers rotate the plane of polarization of light in opposite directions, a racemic sample is not optically active.

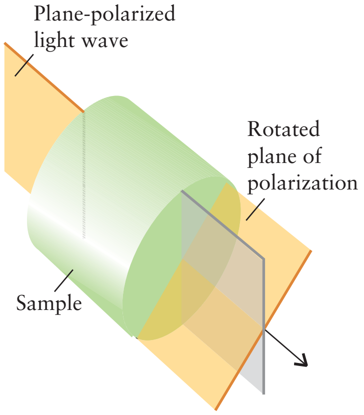


FIGURE 16.24 Plane-polarized light consists of radiation in which all the wave motion lies in one plane (as represented by the plane on the left). When such light passes through a solution of an optically active substance, the plane of the polarization is rotated through a characteristic angle that depends on the identity and concentration of the solute and the length of the path through the sample (right).

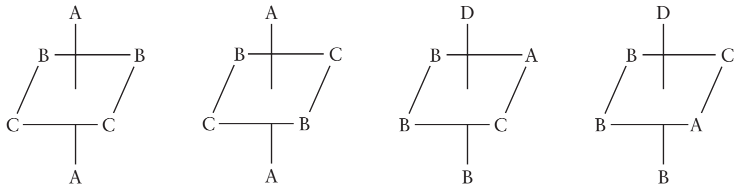
EXAMPLE 16.2 Identifying optical isomerism

Which of the following complexes are chiral, and which form enantiomeric pairs?



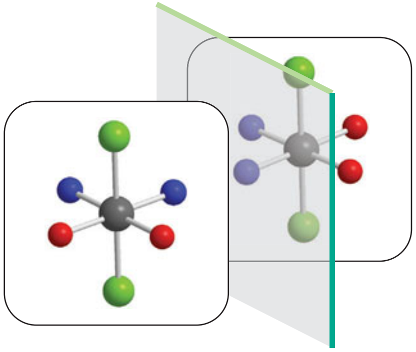
(a) (b) (c) (d)

PLAN Draw the mirror image of each complex and mentally rotate it; judge whether any rotation will allow the mirror image to be superimposed on the original molecule. If not, then the complex is chiral. Determine which complexes form enantiomeric pairs by finding pairs in which the two complexes are the nonsuperimposable mirror images of each other. If imagining the three-dimensional structure is difficult, build simple paper models of the complexes.

SOLVE The mirror image of each complex is shown on the right of each pair.

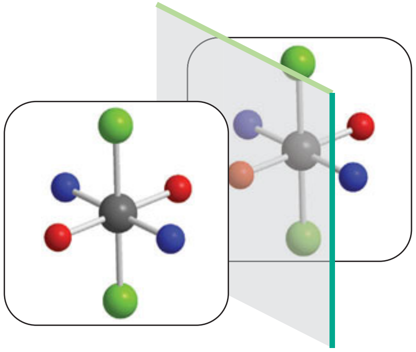
(a) Rotating the mirror image about the vertical axis gives a structure identical to the original, and so superimposable on it.

Not chiral



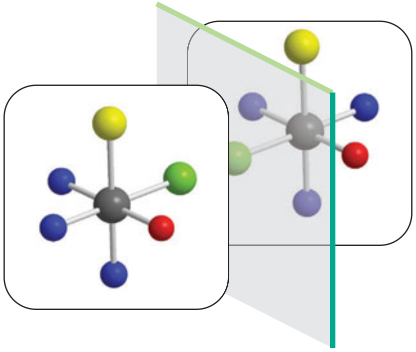
(b) The mirror image is superimposable on the original.

Not chiral



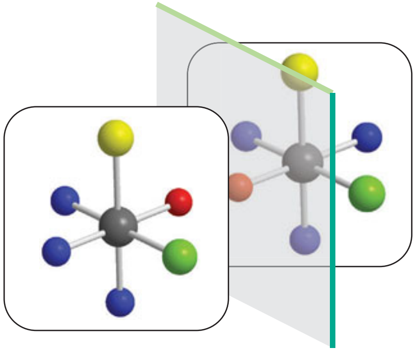
(c) No rotation will allow the complex to be superimposed on its mirror image.

Chiral



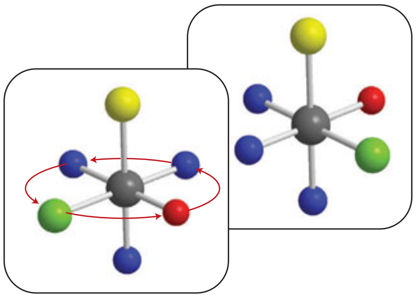
(d) No rotation will allow the complex to be superimposed on its mirror image.

Chiral

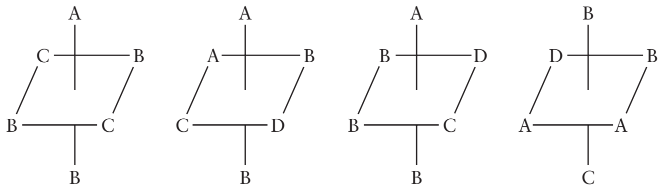


When the mirror image of (c) is rotated by 90° around the vertical axis, it becomes the complex (d).

(c) and (d) are a pair of enantiomers.



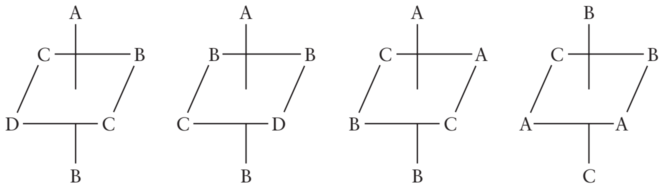
Self-Test 16.6A Repeat Example 16.2 for the following complexes:



(a) (b) (c) (d)

[***Answer:*** (a) Not chiral; (c) chiral; (b, d) chiral and enantiomeric]

Self-Test 16.6B Repeat Example 16.2 for the following complexes:



(a) (b) (c) (d)

The varieties of isomerism are summarized in Fig. 16.19. Enantiomeric pairs of optical isomers rotate the plane of polarization of light in opposite directions.

THE ELECTRONIC STRUCTURES OF COMPLEXES

The striking feature of many coordination compounds is that they are colored or paramagnetic or both. How do these properties arise? To find out, we need to understand the electronic structures of complexes, the details of the bonding, and how their electrons are distributed.

There are two major theories of bonding in d-metal complexes. "Crystal field theory" was first devised to explain the colors of solids, particularly ruby, which owes its color to Cr^{3+} ions, and then adapted to individual complexes. Crystal field theory is simple to apply and enables us to make useful predictions with very little labor. However, it does not account for all the properties of complexes. A more sophisticated approach, "ligand field theory" (Section 16.12), is based on molecular orbital theory and provides more detailed explanations.

16.8 Crystal Field Theory

Crystal field theory takes a very simple view of the environment of the central metal atom (or ion): it supposes that each ligand can be represented by a point negative charge. These negative charges represent the ligand lone pairs directed toward the central metal atom (Fig. 16.25). Because the metal atom at the center of a complex is usually a positively charged ion, the negative charges representing the ligands are attracted to it. This attraction results in the formation of the complex. However, in most cases, there are still d-electrons on the central metal ion and the point charges representing the ligands interact with each electron to different extents that depend on the orientation of the d-orbital that it occupies. Crystal field theory explores these differences and uses them to account for the optical and magnetic properties of the complex.

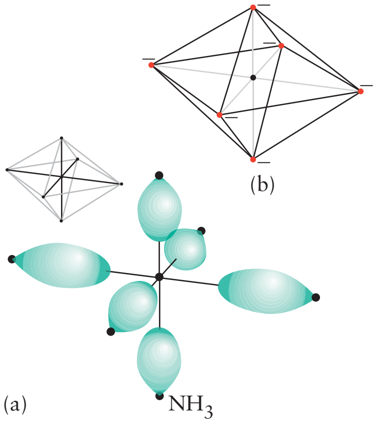


FIGURE 16.25 In the crystal field theory of complexes, the lone pairs of electrons that serve as the Lewis base sites on the ligands (a) are treated as equivalent to point negative charges (b).

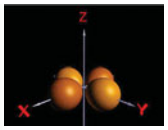
As an example, let's consider an octahedral d^1 complex, such as one containing a Ti^{3+} ion. In a free Ti^{3+} ion, all five 3d-orbitals have the same energy and the d-electron is equally likely to occupy any one of them. However, when a Ti^{3+} ion is dissolved in water, six H_2O molecules surround it and form a $[Ti(OH_2)_6]^{3+}$ complex. The six point charges representing the ligands lie on opposite sides of the central metal ion along the *x*-, *y*-, and *z*-axes. From Fig. 16.26, we can see that three of the orbitals (d_{xy}, d_{yz}, and d_{zx}) have their lobes directed *between* the point charges. These three d-orbitals are called **t_{2g}-orbitals.** The other two d-orbitals (d_{z^2} and $d_{x^2-y^2}$), have lobes that point *directly toward* the point charges, and are called **e_g-orbitals.** Because the negative point charges representing the

The labels t_{2g} and e_g are derived from group theory, the mathematical theory of symmetry. The letter g indicates that the orbital does not change sign when we start from any point, pass through the nucleus, and end at the corresponding point on the other side of the nucleus.



Animation 16.26

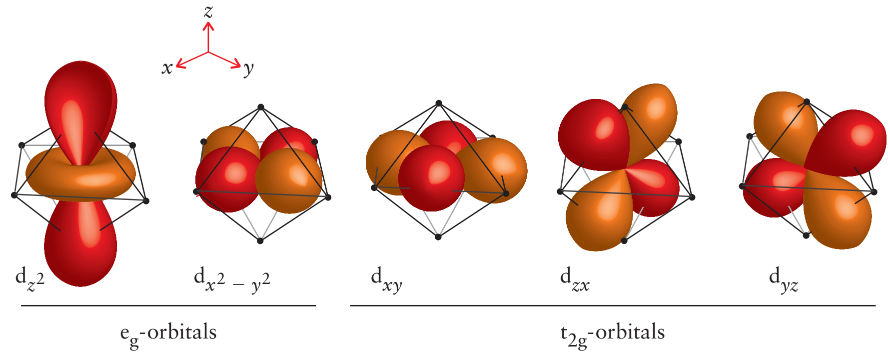


FIGURE 16.26 In an octahedral complex with a central d-metal atom or ion, a d_{xy}-orbital is directed between the ligand sites, and an electron that occupies it has a relatively low energy. The same lowering of energy occurs for d_{yz}- and d_{zx}-orbitals. A d_{z^2}-orbital points directly toward two ligands, and an electron that occupies it has a relatively high energy. The same rise in energy occurs for a $d_{x^2-y^2}$-electron.

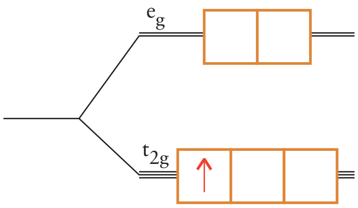
ligands repel electrons, the energy of the single d-electron is increased, but it is raised more if it occupies an e_g-orbital than if it occupies a t_{2g}-orbital.

To express the fact that an electron in an octahedral complex has a different energy depending on which of the orbitals it occupies, we say that the three t_{2g}-orbitals have a lower energy than the two e_g-orbitals. The stability of a complex depends on the interaction energy between the central positive ion and its ligands. Typically the difference in energies of electrons in the t_{2g}- and the e_g-orbitals accounts only for about 10% of that energy, but it plays a major role in the optical and magnetic properties of the complex.

The energy-level diagram for an octahedral complex in Fig. 16.27 helps to summarize these ideas. The energy separation between the two sets of orbitals is called the **ligand field splitting,** Δ_O (the O denotes octahedral). The three t_{2g}-orbitals lie at an energy that is $\frac{2}{5}\Delta_O$ below the average d-orbital energy in the complex, and the two e_g-orbitals lie at an energy $\frac{3}{5}\Delta_O$ above the average. Because the t_{2g}-orbitals have the lower energy, we can predict that, in the ground state of the $[Ti(OH_2)_6]^{3+}$ complex, the electron occupies one of them in preference to an e_g-orbital and hence that the lowest energy electron configuration of the complex is $t_{2g}{}^1$. This ground-state configuration is represented by the box diagram in (**16**).



16 $t_{2g}{}^1$

The single d-electron of an octahedral $[Ti(OH_2)_6]^{3+}$ complex can be excited from the t_{2g}-orbital into an e_g-orbital if it absorbs a photon of energy Δ_O (Fig. 16.28). The greater the splitting, the shorter the wavelength of the light that is absorbed by the complex. Therefore, we can use the wavelength of the electromagnetic radiation absorbed by a complex to determine the ligand field splitting.

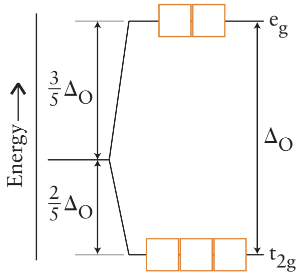


FIGURE 16.27 The energy levels of the d-orbitals in an octahedral complex with the ligand field splitting Δ_O. The horizontal line on the far left represents the average energy of the d-orbitals once the complex has formed; the lines on the right show the modification of their energies due to their different interactions with the ligands. Each orbital (represented by a box) can hold two electrons.

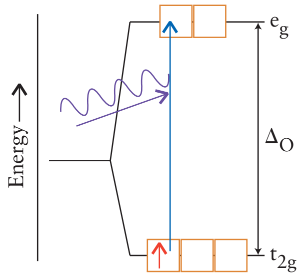

FIGURE 16.28 When a complex is exposed to light with the correct frequency, an electron can be excited to a higher energy orbital and a photon of light is absorbed.

EXAMPLE 16.3 **Determining the ligand field splitting**

The complex $[Ti(OH_2)_6]^{3+}$ absorbs light of wavelength 510. nm. What is the ligand field splitting in the complex in kilojoules per mole ($kJ\cdot mol^{-1}$)?

PLAN Because a photon carries an energy $h\nu$, where h is Planck's constant and ν (nu) is the frequency of the radiation, it can be absorbed if $h\nu = \Delta_O$. The wavelength, λ (lambda), of light is related to the frequency by $\lambda = c/\nu$, where c is the speed of light (Section 1.2). Therefore, the wavelength of light absorbed and the ligand field splitting are related by

$$\Delta_O = \frac{hc}{\lambda}$$

To report the ligand field splitting as a molar energy, multiply this expression by Avogadro's constant:

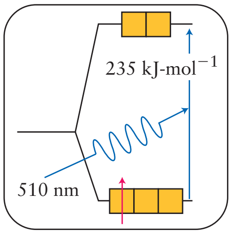
$$\Delta_O = \frac{N_A hc}{\lambda}$$

SOLVE Because the wavelength absorbed is 510. nm (corresponding to 5.10×10^{-7} m), it follows that the ligand field splitting is:

From $\Delta_O = N_A hc/\lambda$,

$$\Delta_O = \frac{(6.022 \times 10^{23}\,mol^{-1}) \times (6.626 \times 10^{-34}\,J\cdot s) \times (2.998 \times 10^{8}\,m\cdot s^{-1})}{5.10 \times 10^{-7}\,m}$$

$$= 2.35 \times 10^{5}\,J\cdot mol^{-1} = 235\,kJ\cdot mol^{-1}$$



Self-Test 16.7A The complex $[Fe(OH_2)_6]^{3+}$ absorbs light of wavelength 700. nm. What is the value (in kilojoules per mole) of the ligand field splitting?

[***Answer:*** $171\,kJ\cdot mol^{-1}$]

Self-Test 16.7B The complex $[Fe(CN)_6]^{4-}$ absorbs light of wavelength 305 nm. What is the value (in kilojoules per mole) of the ligand field splitting?

The relative energies of the d-orbitals are different in complexes with different shapes. For example, in a tetrahedral complex, the three t_2-orbitals point more directly at the ligands than the two e-orbitals do. As a result, in a tetrahedral complex, the t_2-orbitals have a higher energy than the e-orbitals (Fig. 16.29). The ligand field splitting, Δ_T (where the T denotes tetrahedral), is generally smaller than in octahedral complexes, in part because there are fewer repelling ligands.

The subscript g is not used to label the orbitals in a tetrahedral complex because there is no center of symmetry.

Thinking point: Into what groups do you think the d-orbitals are split in a square-planar complex?

> ***In octahedral complexes, the e_g-orbitals (d_{z^2} and $d_{x^2-y^2}$) lie higher in energy than the t_{2g}-orbitals (d_{xy}, d_{yz}, and d_{zx}). The opposite is true in a tetrahedral complex, for which the ligand field splitting is smaller.***

16.9 The Spectrochemical Series

Different ligands affect the d-orbitals of a given metal atom or ion to different degrees and thus produce different values of the ligand field splitting. For example, the ligand field splitting is much greater in $[Fe(CN)_6]^{4-}$ than it is in $[Fe(OH_2)_6]^{2+}$. The relative strengths of the splitting produced by a given ligand are much the same regardless of the identity of the d-metal in the complex. Thus, ligands can be arranged in a **spectrochemical series** according to the relative magnitudes of the ligand field splittings that they produce (Fig. 16.30). Ligands below the horizontal line in Fig. 16.30 produce only a small ligand field splitting, and so they are called **weak-field ligands;** ligands above

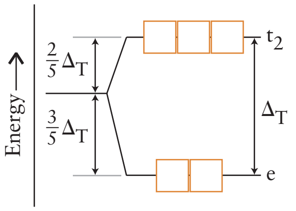


FIGURE 16.29 The energy levels of the d-orbitals in a tetrahedral complex with the ligand field splitting Δ_T. Each box (that is, orbital) can hold two electrons. The subscript g is not used to label the orbitals in a tetrahedral complex.

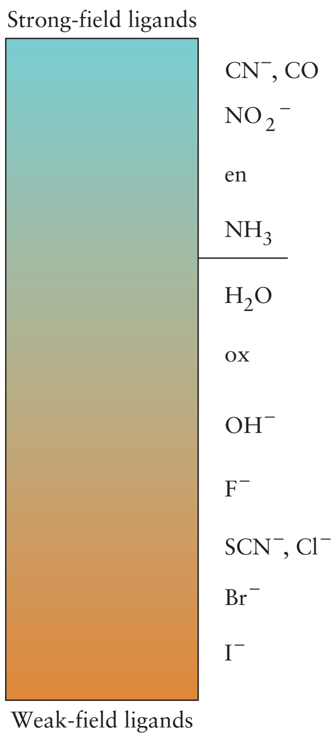

FIGURE 16.30 The spectrochemical series. Strong-field ligands give rise to a large splitting between the t- and e-orbitals, whereas weak-field ligands give rise to only a small splitting. The horizontal line marks the approximate frontier between the two kinds of ligands. The changing color represents the increasing energy of light absorbed as the field strength increases.

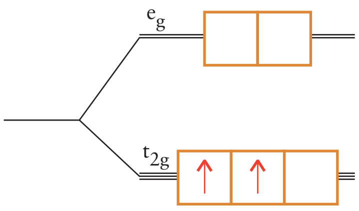
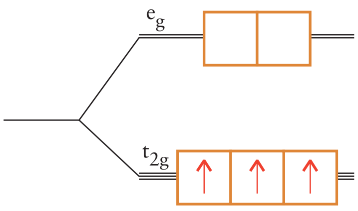
the line produce a larger splitting and are called **strong-field ligands.** A CN^- ion is therefore a strong-field ligand, whereas an H_2O molecule is a weak-field ligand.

Knowledge of relative ligand strengths allows us to understand the color of a complex ion and, as we shall see in Section 16.11, its magnetism as well. The replacement of one ligand by another gives us chemical control over color. Similarly, the substitution of weak-field ligands for strong-field ligands (or vice versa) acts like a chemical switch for turning paramagnetism on and off. The key idea is that the ligand field splitting affects the electron configuration of the complex. Because all five d-orbitals of an isolated metal atom or ion have the same energy, electrons occupy each orbital separately (Hund's rule, Section 1.13) until five electrons have been accommodated. When the atom is part of a complex, we also have to take into account the difference in energies between the t_{2g} and e_g orbitals, because the order in which they are occupied depends on that difference.

First, consider the metal atom or ion at the center of an octahedral complex. The energies of its d-orbitals are split by the ligands as shown in Fig. 16.27. The three t_{2g}-orbitals all have the same energy and lie below the two e_g-orbitals. The single d-electron of a d^1 complex occupies one of the t_{2g}-orbitals, and so the ground-state configuration is $t_{2g}^{\ 1}$ (see **16**). The two d-electrons of a d^2 complex occupy separate t_{2g}-orbitals and give rise to the configuration $t_{2g}^{\ 2}$ (**17**). Similarly, a d^3 complex will have the ground-state configuration $t_{2g}^{\ 3}$ (**18**). According to Hund's rule, all these electrons have parallel spins, because that arrangement corresponds to the lowest energy.

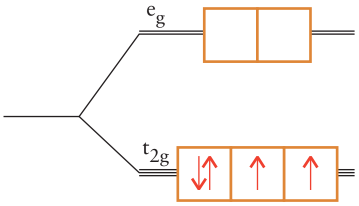


17 $t_{2g}^{\ 2}$

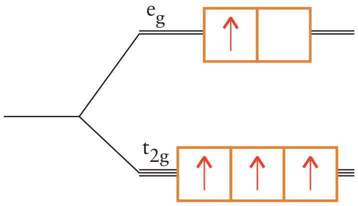


18 $t_{2g}^{\ 3}$

A d^4 octahedral complex presents a problem. The fourth electron could enter a t_{2g}-orbital, resulting in a $t_{2g}^{\ 4}$ configuration. However, to do so, it would have to enter an orbital that is already half full; hence, it would experience a strong repulsion from the electron already there (**19**). To avoid this repulsion, it could occupy an empty e_g-orbital to give a $t_{2g}^{\ 3}e_g^{\ 1}$ configuration (**20**), but now it experiences a strong repulsion from the ligands. Which configuration has the lower energy depends on the ligands present. If Δ_O is large (as it is for strong-field ligands), the energy difference between the t_{2g}- and e_g-orbitals will be large and the configuration $t_{2g}^{\ 4}$ will have a lower energy than $t_{2g}^{\ 3}e_g^{\ 1}$. If Δ_O is small (as it is for weak-field ligands), $t_{2g}^{\ 3}e_g^{\ 1}$ will be the lower energy configuration and hence the one adopted by the complex.



19 $t_{2g}^{\ 4}$



20 $t_{2g}^{\ 3}e_g^{\ 1}$

A note on good practice: Note that a configuration with a single electron in an orbital is written with a superscript 1, as in $t_{2g}^{\ 3}e_g^{\ 1}$, not $t_{2g}^{\ 3}e_g$.

EXAMPLE 16.4 Predicting the electron configuration of a complex

Predict the electron configuration of an octahedral d^5 complex with (a) strong-field ligands and (b) weak-field ligands, and state the number of unpaired electrons in each case.

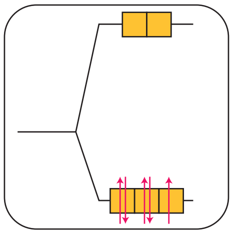
Anticipate (a) For strong-field ligands the energy levels are widely separated, and so we should expect the electrons to pair in the lower-energy orbitals, resulting in fewer unpaired electrons. (b) For weak-field ligands the energy levels are close together, so we should expect the electrons to be distributed across all the orbitals, resulting in the maximum number of unpaired electrons.

PLAN Add electrons to the orbitals in accordance with the building-up principle, to obtain the lowest energy configuration.

SOLVE

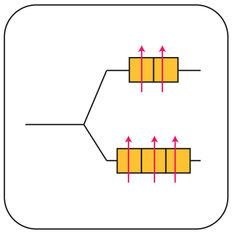
(a) Because Δ_O is large, all five electrons enter the t_{2g}-orbitals and four electrons must pair.

t_{2g}^5; 1 unpaired electron



(b) Because Δ_O is small, the five electrons occupy all five orbitals without pairing.

$t_{2g}^3e_g^2$; 5 unpaired electrons



Evaluate As expected, the number of unpaired electrons is greater for weak-field ligands than it is for strong-field ligands.

Self-Test 16.8A Predict the electron configurations and the number of unpaired electrons of an octahedral d^6 complex with (a) strong-field ligands and (b) weak-field ligands.

[***Answer:*** (a) t_{2g}^6, 0; (b) $t_{2g}^4e_g^2$, 4]

Self-Test 16.8B Predict the electron configurations and the number of unpaired electrons of an octahedral d^7 complex with (a) strong-field ligands and (b) weak-field ligands.

Table 16.5 lists the configurations for d^1 through d^{10} octahedral complexes, including the alternative configurations for d^4 through d^7 octahedral complexes. A d^n complex

TABLE 16.5 Electron Configurations of d^n Complexes

Number of d-electrons	Configuration: Octahedral complexes		Configuration: Tetrahedral complexes
d^1	t_{2g}^1		e^1
d^2	t_{2g}^2		e^2
d^3	t_{2g}^3		$e^2t_2^1$
	Low spin	High spin	
d^4	t_{2g}^4	$t_{2g}^3e_g^1$	$e^2t_2^2$
d^5	t_{2g}^5	$t_{2g}^3e_g^2$	$e^2t_2^3$
d^6	t_{2g}^6	$t_{2g}^4e_g^2$	$e^3t_2^3$
d^7	$t_{2g}^6e_g^1$	$t_{2g}^5e_g^2$	$e^4t_2^3$
d^8	$t_{2g}^6e_g^2$		$e^4t_2^4$
d^9	$t_{2g}^6e_g^3$		$e^4t_2^5$
d^{10}	$t_{2g}^6e_g^4$		$e^4t_2^6$

with the maximum number of unpaired spins is called a **high-spin complex.** High-spin complexes are expected for weak-field ligands because the electrons can easily occupy both the t_{2g}- and the e_g-orbitals, and the greatest number of electrons then have parallel spins. A d^n complex with the minimum number of unpaired spins is called a **low-spin complex.** We should expect a low-spin complex when the ligands are strong-field, because electrons enter the t_{2g}-orbitals until they are completely full, even though they have to pair their spins. We can predict whether an octahedral complex is likely to be a high-spin or a low-spin complex by noting where the ligands lie in the spectrochemical series. If they are strong-field ligands, we expect a low-spin complex; if they are weak-field ligands, we expect a high-spin complex.

Tetrahedral complexes are almost always high spin. We saw that ligand field splittings are smaller for tetrahedral than for octahedral complexes. Therefore, even if the ligands are classified as strong-field ligands for octahedral complexes, the splitting is so small in the corresponding tetrahedral complex that the t_2-orbitals are energetically accessible.

The electron configurations of d-block metal atoms and ions in complexes are obtained by applying the building-up principle to the d-orbitals, taking into account the strength of the ligand field splitting. Relative field-splitting strengths are summarized by the spectrochemical series.

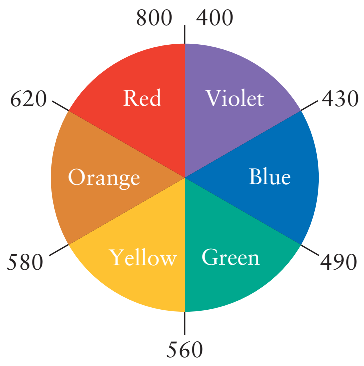


FIGURE 16.31 In a color wheel the color of light absorbed is opposite the color perceived. For example, a complex that absorbs orange light appears blue to the eye.

16.10 The Colors of Complexes

White light is a mixture of all wavelengths of electromagnetic radiation from about 400 nm (violet) to about 800 nm (red). When some of these wavelengths are removed from a beam of white light by passing the light through a sample, the emerging light is no longer white to the eye. For example, if red light is absorbed from white light, then the light that remains appears green. Conversely, if green is removed, then the light appears red. We say that red and green are each other's **complementary color**—each is the color that white light appears when the other is removed (Fig. 16.31).

We can see from the color wheel that, for example, if a substance looks blue (as does a copper(II) sulfate solution, for instance), then it is absorbing orange (580–620 nm) light. Conversely, if we know the wavelength (and therefore the color) of the light that a substance absorbs, then we can predict the color of the substance by noting the complementary color on the color wheel. Because $[Ti(OH_2)_6]^{3+}$ absorbs 510-nm light, which is yellow-green light, the complex looks violet (Fig. 16.32).

FIGURE 16.32 Because $[Ti(H_2O)_6]^{3+}$ absorbs yellow-green light (of wavelengths close to 510 nm), it looks violet in white light.

Because weak-field ligands generate small splittings, the complexes that they form absorb low-energy, long-wavelength radiation. The long wavelengths correspond to red light, and so these complexes exhibit colors near green. Because strong-field ligands result in large splittings, the complexes that they form should absorb high-energy, short-wavelength radiation, corresponding to the violet end of the visible spectrum. Such complexes can therefore be expected to have colors near orange and yellow (Fig. 16.33).

FIGURE 16.33 The effect on the color of the complex of substituting ligands with different ligand field strengths in octahedral cobalt(III) complexes in aqueous solution.

The colors that we have described arise from **d–d transitions,** in which an electron is excited from one d-orbital into another. In a **charge-transfer transition** an electron is excited from a ligand onto the metal atom or vice versa. Charge-transfer transitions are often very intense and are the most common cause of the familiar colors of d-metal complexes, such as the transition responsible for the deep purple of permanganate ions, MnO_4^- (Fig. 16.34).

Transitions between d-orbitals or between the ligands and the metal atom in complexes give rise to color; the wavelength of d–d transitions can be correlated with the magnitude of the ligand field splitting.

FIGURE 16.34 In a ligand-to-metal charge-transfer transition, an energetically excited electron migrates from a ligand to the central metal ion. This type of transition is responsible for the intense purple of the permanganate ion, MnO_4^-.

16.11 Magnetic Properties of Complexes

As we saw in Box 3.2, a substance with unpaired electrons is paramagnetic and is pulled into a magnetic field. A substance without unpaired electrons is diamagnetic and is pushed out of a magnetic field. Many d-metal complexes have unpaired d-electrons and are therefore paramagnetic. We have just seen that a high-spin d^n complex has more unpaired electrons than does a low-spin d^n complex. A high-spin complex is therefore more strongly paramagnetic than a low-spin complex with the same number of d-electrons. Whether a complex is high spin or low spin depends on the ligands present. The d^4 through d^7 complexes of strong-field ligands have large energy gaps and so tend to be low spin and therefore only weakly paramagnetic or diamagnetic (Fig. 16.35). The d^4 through d^7 complexes of weak-field ligands have only a small energy gap between the t_{2g} and e_g orbitals and therefore tend to be high spin and strongly paramagnetic.

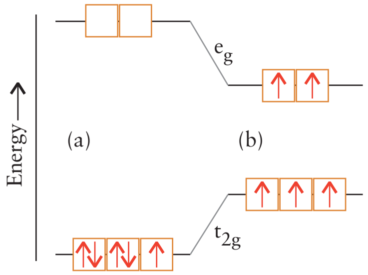

FIGURE 16.35 (a) A strong-field ligand is likely to lead to a low-spin complex (in this case, the configuration is that of Fe^{3+}). (b) Substituting weak-field ligands is likely to result in a high-spin complex.

EXAMPLE 16.5 Predicting the magnetic properties of a complex

Compare the magnetic properties of (a) $[Fe(OH_2)_6]^{2+}$; (b) $[Fe(CN)_6]^{4-}$.

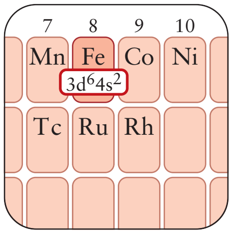
Anticipate Because H_2O is a weak-field ligand, we should expect the maximum number of unpaired electrons; hence, it is likely to be high spin and thus paramagnetic. The CN^- ion is a strong-field ion and so its complexes are likely to be low spin and thus diamagnetic.

PLAN To predict the magnetic properties of a complex, we need to know both the number of electrons on the central atom or ion and the position of the ligands in the spectrochemical series. Decide from their positions in the spectrochemical series whether the ligands are weak-field or strong-field. Then judge whether the complex is high spin or low spin.

SOLVE

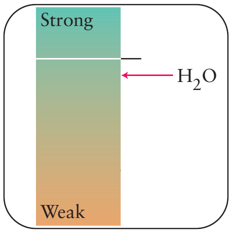
(a) Determine the number of d-electrons.

The Fe^{2+} ion is a d^6 ion.



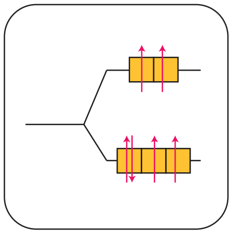
Classify the ligand strength.

H_2O is a weak-field ligand.



For a weak-field ligand, predict a high-spin $t_{2g}^4e_g^2$ configuration.

$[Fe(OH_2)_6]^{2+}$ will have 4 unpaired electrons; therefore, paramagnetic.

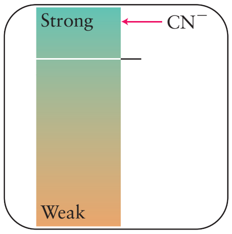


(b) Determine the number of d-electrons.

The Fe^{2+} ion is a d^6 ion.

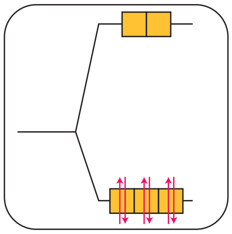
Classify the strength of the ligand.

CN^- is a strong-field ligand.



For a strong-field ligand, predict a low-spin t_{2g}^6 configuration.

$[Fe(CN)_6]^{4-}$ will have no unpaired electrons; therefore, diamagnetic.



Evaluation As expected, the aqua complex is paramagnetic and the cyanido complex diamagnetic.

Self-Test 16.9A What change in magnetic properties can be expected when NO_2^- ligands in an octahedral complex are replaced by Cl^- ligands in (a) a d^6 complex; (b) a d^3 complex?

[***Answer:*** (a) The complex becomes paramagnetic; (b) there is no change in magnetic properties.]

Self-Test 16.9B Compare the magnetic properties of $[Ni(en)_3]^{2+}$ with those of $[Ni(OH_2)_6]^{2+}$.

The magnetic properties of a complex depend on the magnitude of the ligand field splitting. Strong-field ligands tend to form low-spin, weakly paramagnetic complexes; weak-field ligands tend to form high-spin, strongly paramagnetic complexes.

16.12 Ligand Field Theory

Crystal field theory is based on a very primitive model of bonding. For example, ligands are not point charges: they are actual molecules or ions. The theory also leaves several questions unanswered. Why, for instance, is the electrically neutral molecule CO a strong-field ligand but the negatively charged ion Cl^- a weak-field ligand?

To improve the model of bonding in complexes, chemists have turned to molecular orbital theory (Section 3.9). **Ligand field theory** describes bonding in complexes in terms of molecular orbitals built from the metal atom d-orbitals and ligand orbitals. In contrast to crystal field theory, which models the structure of the complex in terms of point charges, ligand field theory assumes, more realistically, that ligands are attached to the central metal atom or ion by covalent bonds. As we shall see, much of the work that we have done in connection with crystal field theory can be transferred into ligand field theory: the principal difference is the origin of the ligand field splitting.

To describe the electronic structure of a complex, first we set up molecular orbitals from the available atomic orbitals in the complex, just as we would for a molecule. Consider an octahedral complex of a d-metal in Period 4, such as iron, cobalt, or copper. We need to consider the nine 4s-, 4p-, and 3d-orbitals of the central metal ion, because all these orbitals have similar energies. To simplify the discussion, we use only one atomic orbital on each of the ligands. For instance, for a Cl^- ligand, we use the Cl3p-orbital directed toward the metal atom; for an NH_3 ligand, we use the sp^3 lone-pair orbital of the nitrogen atom. The six orbitals provided by the six ligands in an octahedral complex are represented by the tear-shaped lobes in Fig. 16.36. Each of these orbitals has cylindrical symmetry around the metal–ligand axis, and so each can form a σ-orbital.

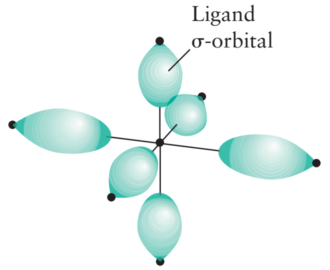


FIGURE 16.36 The tear-shaped objects are representations of the six ligand atomic orbitals that are used to build the molecular orbitals of an octahedral complex in ligand field theory. They might represent s- or p-orbitals on the ligands or hybrids of the two.

There are nine valence orbitals on the metal atom and six on the ligands, giving 15 in all. We can therefore expect to find 15 molecular orbitals: it turns out, as we explain in a moment, that six are bonding, three are nonbonding, and six are antibonding. The energies of all 15 are displayed in Fig. 16.37, together with the labels that they are commonly given. Notice in Fig.16.37 that the t_{2g}-orbitals on the metal atom have no partners among the ligands. There are simply no ligand orbitals to match them. Therefore, these three orbitals are nonbonding orbitals in the complex, whereas the e_g orbitals are antibonding.

Now we proceed exactly as we did in the discussion of diatomic molecules (Section 3.10): we use the building-up principle to work out the ground-state electron configuration. First, we need to count the available electrons. In a d^n complex, n electrons are supplied by the metal; each ligand orbital supplies two electrons, and so 12 electrons are supplied by the ligands, giving $12 + n$ in all. The first 12 electrons fill the six bonding orbitals. That leaves n electrons to be accommodated in the nonbonding and antibonding orbitals. At this point, notice that the next available orbitals (those in the upper, dark red box in Fig. 16.37) lie in exactly the same pattern as that encountered in crystal field theory. The only difference is that, in ligand field theory, we recognize the three t_{2g}-orbitals as nonbonding orbitals and the two e_g-orbitals as antibonding between the metal and the ligands. That is, the ligand field splitting can be identified with the energy separation between nonbonding and antibonding orbitals. The remaining four orbitals are high-energy antibonding orbitals that are ordinarily unavailable to the electrons.

From this point on, the analysis is the same as in crystal field theory. The order of filling these two sets of orbitals is exactly the same as in crystal field theory, and so is the discussion of optical and magnetic properties. If the ligand field splitting is large, then the t_{2g}-orbitals are filled first, and we can expect a low-spin complex. If the ligand field splitting is small, then the e_g-orbitals are occupied before spin-pairing begins in the t_{2g}-orbitals, and we expect a high-spin complex.

Although ligand field theory puts the discussion of bonding on a firmer basis, it has not yet explained all the puzzling features of crystal field theory. In particular, why is CO a strong-field ligand? Why is Cl^- a weak-field ligand despite its negative charge?

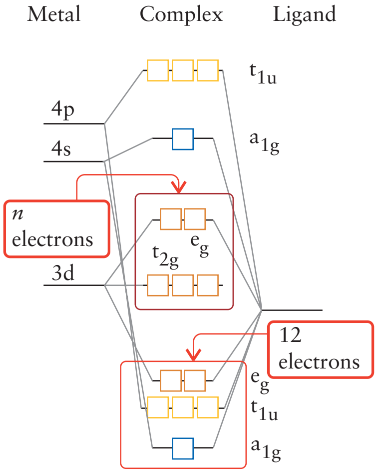

FIGURE 16.37 The molecular orbital energy-level diagram for an octahedral complex. The 12 electrons provided by the six ligands fill the lowest six orbitals, which are all bonding orbitals. The n d-electrons provided by the central metal atom or ion are accommodated in the orbitals inside the upper box. The ligand field splitting is the energy separation of the nonbonding (t_{2g}) and antibonding (e_g) orbitals in the box.

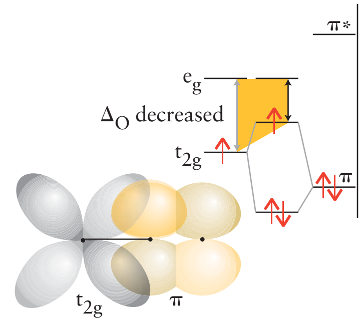
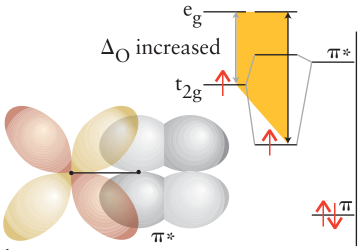
We need to develop the model by considering the effects of other ligand orbitals. When we constructed the molecular orbitals, we considered only ligand orbitals that pointed directly at the central metal atom. Ligands also have orbitals perpendicular to the metal–ligand axis, which we can expect to contribute to bonding and antibonding π-orbitals. As Fig. 16.38 shows, a p-orbital on the ligand perpendicular to the axis of the metal–ligand bond can overlap with one of the t_{2g}-orbitals to produce two new molecular orbitals, one bonding and one antibonding. The resulting bonding orbital lies below the energy of the original t_{2g}-orbitals; the antibonding orbital lies above them.

Now we count the number of electrons to accommodate. If the ligand is Cl^-, the Cl3p-orbital that we have used to build the metal–ligand π-orbital is full. It provides two electrons, which occupy a new molecular orbital, the bonding metal–ligand combination shown in Fig. 16.38a. The n d-electrons provided by the metal must therefore occupy the *antibonding* metal–ligand orbital. Because this molecular orbital is higher in energy than the original t_{2g}-orbitals, the ligand field splitting is decreased by π-bonding. We see how Cl^- can be a weak-field ligand despite its negative charge.



(a)



(b)

FIGURE 16.38 The effect of π-bonding on ligand field splitting. (a) In this case, the occupied π-orbital of the ligand is close in energy to the ligand t_{2g} orbitals and they overlap to form bonding and antibonding combinations. The ligand-field splitting is reduced. (b) In this case, the unoccupied antibonding π*-orbital of the ligand is close in energy to the ligand t_{2g} orbitals and they overlap to form bonding and antibonding combinations. In this case, the ligand-field splitting is increased.

Now suppose the ligand is CO. The orbital that overlaps with the metal t_{2g}-orbitals in this case is either the full bonding π-orbital or the empty antibonding π*-orbital of the CO molecule. It turns out that the latter orbital is closer in energy to the metal orbitals, and so it plays the dominant role in bond formation to the metal, as in Fig. 16.38b. There are no electrons from the ligand to accommodate because its π*-orbital is empty. The n d-electrons therefore enter the *bonding* metal–ligand orbital. Because this new molecular orbital is lower in energy than the original t_{2g}-orbitals, the ligand field splitting is increased by π-bonding and CO is a strong-field ligand despite being electrically neutral.

According to ligand field theory, the ligand field splitting is the energy separation between nonbonding and antibonding molecular orbitals built principally from d-orbitals. When π-bonding is possible, the ligand field splitting is decreased if the ligand supplies π-electrons and is increased if the ligand does not supply π-electrons.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Explain trends in chemical and physical properties among the d-block elements (Sections 16.1 and 16.2).

❑ 2 Describe and write balanced equations for the principal reactions used to produce the elements in the first row (Period 4) of the d-block and in Groups 11 and 12 (Sections 16.3 and 16.4).

❑ 3 Describe the names, properties, and reactions of some of the principal compounds of the elements in the first row of the d-block (Sections 16.3 and 16.4).

❑ 4 Describe the operation of a blast furnace and how steel is made (Section 16.3).

❑ 5 Name and write formulas for d-metal complexes (Toolbox 16.1 and Example 16.1).

❑ 6 Identify pairs of ionization, linkage, hydrate, coordination, geometrical, and optical isomers (Self-Tests 16.4 and 16.5 and Example 16.2).

❑ 7 Determine the ligand field splitting from the wavelength of light absorbed by a complex (Example 16.3).

❑ 8 Use the spectrochemical series to predict the effect of a ligand on the color, electron configuration, and magnetic properties of a d-metal complex (Examples 16.4 and 16.5).

❑ 9 Describe bonding in d-metal complexes in terms of ligand field theory (Section 16.12).

EXERCISES

Trends in Properties

You may find Appendix 2 helpful in answering these questions.

16.1 Which members of the d-block, those at the left or at the right of the block, are likely to have the more strongly negative standard potentials? Explain this observation.

16.2 Name five elements in the d-block that have positive standard potentials.

16.3 Identify the element with the larger atomic radius in each of the following pairs: (a) vanadium and titanium; (b) silver and gold; (c) vanadium and tantalum; (d) rhodium and iridium.

16.4 Identify the element with the larger atomic radius in each of the following pairs: (a) iron and chromium; (b) palladium and platinum; (c) tungsten and rhenium; (d) scandium and yttrium.

16.5 Identify the element with the higher first ionization energy in each of the following pairs: (a) iron and nickel; (b) nickel and copper; (c) osmium and platinum; (d) nickel and palladium; (e) hafnium and tantalum.

16.6 Identify the element with the higher first ionization energy in each of the following pairs: (a) manganese and cobalt; (b) manganese and rhenium; (c) chromium and zinc; (d) chromium and molybdenum; (e) palladium and platinum.

16.7 Explain why the density of mercury ($13.55\ g{\cdot}cm^{-3}$) is significantly higher than that of cadmium ($8.65\ g{\cdot}cm^{-3}$), whereas the density of cadmium is only slightly greater than that of zinc ($7.14\ g{\cdot}cm^{-3}$).

16.8 Explain why the density of vanadium ($6.11\ g{\cdot}cm^{-3}$) is significantly less than that of chromium ($7.19\ g{\cdot}cm^{-3}$). Both vanadium and chromium crystallize in a body-centered cubic lattice.

16.9 (a) Describe the trend in the stability of oxidation states moving down a group in the d-block (for example, from chromium to molybdenum to tungsten). (b) How does this trend compare with the trend in the stabilities of oxidation states observed for the p-block elements on moving down a group?

16.10 Which oxoanion, CrO_4^{2-} or WO_4^{2-}, is expected to be the stronger oxidizing agent? Explain your choice.

16.11 Which of the elements vanadium, chromium, and manganese is most likely to form an oxide with the formula MO_3? Explain your answer.

16.12 Which of the elements scandium, molybdenum, and copper is most likely to form a chloride with the formula MCl_4? Explain your answer.

Selected Elements: A Survey

16.13 Predict the major products of each of the following reactions and then balance the skeletal equations:
(a) $TiCl_4(s) + Mg(s) \xrightarrow{\Delta}$
(b) $CoCO_3(s) + HNO_3(aq) \longrightarrow$
(c) $V_2O_5(s) + Ca(l) \xrightarrow{\Delta}$

16.14 Predict the major products of each of the following reactions and then balance the skeletal equations:
(a) $FeCr_2O_4(s) + C(s) \xrightarrow{\Delta}$
(b) $CrO_4^{2-}(s) + H_3O^+(aq) \longrightarrow$
(c) $MnO_2(s) + Al(s) \xrightarrow{\Delta}$

16.15 Give the systematic name and chemical formula of the principal component of (a) rutile; (b) hematite; (c) pyrolusite; (d) chromite.

16.16 Give the systematic name and chemical formula of the principal component of (a) magnetite; (b) malachite; (c) ilmenite; (d) chalcocite.

16.17 (a) What reducing agent is used in the production of iron from its ore? (b) Write chemical equations for the production of iron in a blast furnace. (c) What is the major impurity in the product of the blast furnace?

16.18 (a) What is the purpose of adding limestone to a blast furnace? (b) Write chemical equations that show the reactions of lime in a blast furnace.

16.19 Use Appendix 2B to determine whether an acidic sodium dichromate solution can oxidize (a) bromide ions to bromine and (b) silver(I) ions to silver(II) ions under standard conditions.

16.20 Use Appendix 2B to determine whether an acidic potassium permanganate solution can oxidize (a) chloride ions to chlorine and (b) mercury metal to mercury(I) ions under standard conditions.

16.21 Write the chemical equation that describes each of the following processes: (a) solid V_2O_5 reacts with acid to form the VO^{2+} ion; (b) solid V_2O_5 reacts with base to form the VO_4^{3-} ion.

16.22 Write the chemical equation that describes each of the following processes: (a) the production of chromium by the thermite reaction; (b) the corrosion of copper metal by carbon dioxide in moist air; (c) the purification of nickel by using carbon monoxide.

16.23 By considering electron configurations, explain why gold and silver are less reactive than copper.

16.24 By considering electron configurations, suggest a reason why iron(III) is readily prepared from iron(II) but the conversion of nickel(II) and cobalt(II) into nickel(III) and cobalt(III) is much more difficult.

16.25 (a) Explain why the dissolution of a chromium(III) salt produces an acidic solution. (b) Explain why the slow addition of hydroxide ions to a solution containing chromium(III) ions first produces a gelatinous precipitate that subsequently dissolves with further addition of hydroxide ions. Write chemical equations showing these aspects of the behavior of chromium(III) ions.

16.26 Some of the atomic properties of manganese differ markedly from its neighbors. For example, at constant pressure it takes 400 kJ (2 sf) to atomize 1.0 mol Cr(s) and 420 kJ to atomize 1.0 mol Fe(s), but only 280 kJ to atomize 1.0 mol Mn(s). Propose an explanation, using the electron configurations of the gaseous atoms, for the lower enthalpy of atomization of manganese.

Coordination Compounds

16.27 Name each of the following complex ions and determine the oxidation number of the metal: (a) $[Fe(CN)_6]^{4-}$; (b) $[Co(NH_3)_6]^{3+}$; (c) $[Co(CN)_5(OH_2)]^{2-}$; (d) $[Co(SO_4)(NH_3)_5]^+$.

16.28 Name each of the following complex ions and determine the oxidation number of the metal: (a) $[CrCl_3(NH_3)_2(OH_2)]^+$; (b) $[Rh(en)_3)]^{3+}$; (c) $[Fe(ox)(Br)_4]^{3-}$; (d) $[Ni(OH)(OH_2)_5]^{2+}$.

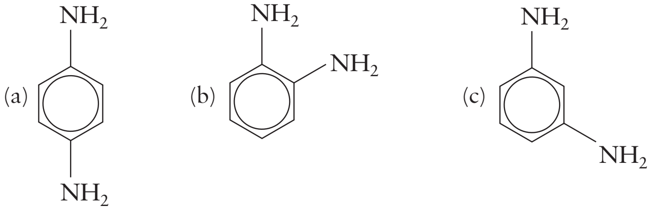
16.29 Use the information in Table 16.4 to write the formula for each of the following coordination compounds:
(a) potassium hexacyanidochromate(III);
(b) pentaamminesulfatocobalt(III) chloride;
(c) tetraamminediaquacobalt(III) bromide;
(d) sodium bisoxalato(diaqua)ferrate(III).

16.30 Use the information in Table 16.4 to write the formula for each of the following coordination compounds:
(a) tetraamminedihydroxidochromium(III) chloride;
(b) sodium tetrachloridoplatinate(II);
(c) triamminetrichloridonickel(IV) sulfate;
(d) sodium tris(oxalato)rhodium(III);
(e) lithium chloridohydroxidobis(oxalato)rhodate(III) octahydrate.

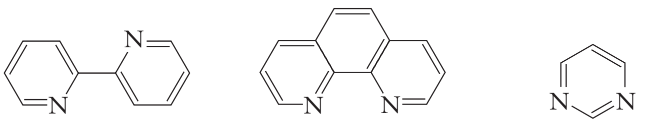
16.31 Which of the following ligands can be polydentate? If the ligand can be polydentate, give the maximum number of places on the ligand that can bind simultaneously to a single metal center: (a) $HN(CH_2CH_2NH_2)_2$; (b) CO_3^{2-}; (c) H_2O; (d) oxalate.

16.32 Which of the following ligands can be polydentate? If the ligand can be polydentate, give the maximum number of places on the ligand that can bind simultaneously to a single metal center: (a) chloride ion; (b) cyanide ion; (c) ethylenediaminetetraacetate; (d) $N(CH_2CH_2NH_2)_3$.

16.33 Which of the following isomers of diaminobenzene can form chelating complexes? Explain.



16.34 Which of the following ligands do you expect to form chelating complexes? Explain.



(a) Bipyridine (b) *ortho*-Phenanthroline (c) Pyrimidine

16.35 With the help of Table 16.4, determine the coordination number of the metal ion in each of the following complexes: (a) $[NiCl_4]^{2-}$; (b) $[Ag(NH_3)_2]^+$; (c) $[PtCl_2(en)_2]^{2+}$; (d) $[Cr(edta)]^-$.

16.36 With the help of Table 16.4, determine the coordination number of the metal ion in each of the following complexes: (a) $[Ir(en)_3)]^{3+}$; (b) $[Fe(ox)_3)]^{3-}$; (c) $[PtCl_2(NH_3)_2]$; (d) $Fe(CO)_5$.

16.37 Identify the type of structural isomerism that exists in each of the following pairs of compounds:
(a) $[Co(\underline{N}O_2)(NH_3)_5]Br_2$ and $[Co(\underline{O}NO)(NH_3)_5]Br_2$
(b) $[Pt(SO_4)(NH_3)_4](OH)_2$ and $[Pt(OH)_2(NH_3)_4]SO_4$
(c) $[CoCl(NC\underline{S})(NH_3)_4]Cl$ and $[CoCl(\underline{N}CS)(NH_3)_4]Cl$
(d) $[CrCl(NH_3)_5]Br$ and $[CrBr(NH_3)_5]Cl$

16.38 Identify the type of structural isomerism that exists in each of the following pairs of compounds:
(a) $[Cr(en)_3][Co(ox)_3]$ and $[Co(en)_3][Cr(ox)_3]$
(b) $[CoCl_2(NH_3)_4]Cl{\cdot}H_2O$ and $[CoCl(NH_3)_4(OH_2)]Cl_2$
(c) $[Co(CN)_5(\underline{N}CS)]^{3-}$ and $[Co(CN)_5(NC\underline{S})]^{3-}$
(d) $[Pt(NH_3)_4][PtCl_6]$ and $[PtCl_2(NH_3)_4][PtCl_4]$

16.39 Which of the following coordination compounds can have cis and trans isomers? If such isomerism exists, draw the two structures and name the compound: (a) $[CoCl_2(NH_3)_4]Cl{\cdot}H_2O$; (b) $[CoCl(NH_3)_5]Br$; (c) $[PtCl_2(NH_3)_2]$, a square planar complex.

16.40 Which of the following coordination compounds can have cis and trans isomers? If such isomerism exists, draw the two structures and label the compounds: (a) $[Fe(OH)_2(OH_2)_4]^+$; (b) $[RuBr(NH_3)_4]^{2+}$; (c) $[Co(NH_3)_3(OH_2)_3]^{3+}$.

16.41 How many isomers are possible for $[Cr(NO_2)(NH_3)_5]Cl_2$? Consider all types of isomerism and draw each isomer.

16.42 How many isomers are possible for $[CoCl(NCS)(OH_2)_4]Cl{\cdot}H_2O$? Consider all types of isomerism and draw each isomer.

16.43 Is either of the following complexes chiral? If both complexes are chiral, do they form an enantiomeric pair?

(a) 
(b) 
16.44 Is either of the following complexes chiral? If both complexes are chiral, do they form an enantiomeric pair?

(a) 
(b) 
The Electronic Structures of Complexes

16.45 Determine the number of valence electrons present in each of the following metal ions: (a) Ti^{2+}; (b) Tc^{2+}; (c) Ir^+; (d) Ag^+; (e) Y^{3+}; (f) Zn^{2+}.

16.46 Determine the number of valence electrons present in each of the following metal ions: (a) Co^{2+}; (b) Mo^{4+}; (c) Ru^{4+}; (d) Pt^{2+}; (e) Os^{3+}; (f) V^{3+}.

16.47 Draw an orbital energy-level diagram (like those in Figs. 16.27 and 16.29) showing the configuration of d-electrons on the metal ion in each of the following complexes: (a) $[Co(NH_3)_6]^{3+}$; (b) $[NiCl_4]^{2-}$ (tetrahedral); (c) $[Fe(OH_2)_6]^{3+}$; (d) $[Fe(CN)_6]^{3-}$. Predict the number of unpaired electrons for each complex.

16.48 Draw an orbital energy-level diagram (like those in Figs. 16.27 and 16.29) showing the configuration of d-electrons on the metal ion in each of the following complexes: (a) $[Zn(OH_2)_6]^{2+}$; (b) $[CoCl_4]^{2-}$ (tetrahedral); (c) $[Co(CN)_6]^{3-}$; (d) $[CoF_6]^{3-}$. Predict the number of unpaired electrons for each complex.

16.49 The complexes (a) $[Co(en)_3]^{3+}$ and (b) $[Mn(CN)_6]^{3-}$ have low-spin electron configurations. How many unpaired electrons, if any, are there in each complex?

16.50 The complexes (a) $[FeF_6]^{3-}$ and (b) $[Co(ox)_3]^{4-}$ have high-spin electron configurations. How many unpaired electrons are there in each complex?

16.51 Explain the difference between a weak-field ligand and a strong-field ligand. What measurements can be used to classify them as such?

16.52 Describe the changes that may take place in a compound's properties when weak-field ligands are replaced by strong-field ligands.

16.53 When the paramagnetic $[Fe(CN)_6]^{3-}$ ion is reduced to $[Fe(CN)_6]^{4-}$, the ion becomes diamagnetic. However, when the paramagnetic $[FeCl_4]^-$ ion is reduced to $[FeCl_4]^{2-}$, the ion remains paramagnetic. Explain these observations.

16.54 When the paramagnetic $[Co(CN)_6]^{4-}$ ion is oxidized to $[Co(CN)_6]^{3-}$, the ion becomes diamagnetic. However, when the paramagnetic $[Co(ox)_3]^{4-}$ is oxidized to $[Co(ox)_3]^{3-}$, the ion remains paramagnetic. Explain these observations.

16.55 Of the two complexes (a) $[CoF_6]^{3-}$ and (b) $[Co(en)_3]^{3+}$, one appears yellow and the other appears blue. Match the complex to the color and explain your choice.

16.56 Which of the complexes $[Cu(OH_2)_6]^{2+}$ or $[Cu(Br)_6]^{4-}$ absorbs at the longer wavelength?

16.57 The complex $[Ni(NH_3)_6]^{2+}$ has a ligand field splitting of 209 $kJ{\cdot}mol^{-1}$ and forms a purple solution. What is the wavelength and color of the absorbed light?

16.58 The complex $[TiCl_6]^{3-}$ has a ligand field splitting of 160. $kJ{\cdot}mol^{-1}$ and forms an orange solution. What is the wavelength and color of the absorbed light?

16.59 The complex $[Co(CN)_6]^{3-}$ is pale yellow. (a) How many unpaired electrons are present in the complex? (b) If ammonia molecules replace the cyanide ions as ligands, will the wavelength of the radiation absorbed be longer or shorter?

16.60 In aqueous solution, water competes effectively with bromide ions for coordination to Cu^{2+} ions. The hexaaquacopper(II) ion is the predominant species in solution. However, in the presence of a large concentration of bromide ions, the solution becomes deep violet. This violet color is due to the presence of the tetrabromocuprate(II) ions, which are tetrahedral. This process is reversible, and so the solution becomes light blue again on dilution with water. (a) Write the formulas of the two complex ions of copper(II) that form. (b) Is the change in color from violet to blue on dilution expected? Explain your reasoning.

16.61 Suggest a reason why $Zn^{2+}(aq)$ ions are colorless. Would you expect zinc compounds to be paramagnetic? Explain your answer.

16.62 Suggest a reason why copper(II) compounds are often colored but copper(I) compounds are colorless. Which oxidation number results in paramagnetic compounds?

16.63 Estimate the ligand field splitting for (a) $[CrCl_6]^{3-}$ (λ_{max} = 740 nm), (b) $[Cr(NH_3)_6]^{3+}$ (λ_{max} = 460 nm), and (c) $[Cr(OH_2)_6]^{3+}$ (λ_{max} = 575 nm), where λ_{max} is the wavelength of the most intensely absorbed light. (d) Arrange the ligands in order of increasing ligand field strength.

16.64 Estimate the ligand field splitting for (a) $[Co(CN)_6]^{3-}$ (λ_{max} = 295 nm), (b) $[Co(NH_3)_6]^{3+}$ (λ_{max} = 435 nm), and (c) $[Co(OH_2)_6]^{3+}$ (λ_{max} = 540 nm), where λ_{max} is the wavelength of the most intensely absorbed light. (d) Arrange the ligands in order of increasing ligand field strength.

16.65 Which d-orbitals on the metal ion are used to form σ-bonds between octahedral metal ions and ligands?

16.66 Which d-orbitals on the metal ion are used to form π-bonds between octahedral metal ions and ligands?

16.67 Ligands that can interact with a metal center by forming a π-type bond are commonly called *π-acids* and *π-bases*. The definitions of π-acid and π-base are similar to those used for Lewis acidity. A π-acid is a ligand that can accept electrons by using π-orbitals, and a π-base donates electrons by using π-orbitals. On the basis of these definitions, describe each of the following ligands as either a π-acid, a π-base, or neither: (a) CN^-; (b) Cl^-; (c) H_2O; (d) en. (e) Place them in order of increasing ligand field splitting.

16.68 Describe each of the following ligands as either a π-acid, a π-base, or neither (see Exercise 16.67): (a) NH_3; (b) ox; (c) F^-; (d) CO. (e) Place them in order of increasing ligand field splitting.

16.69 Is the best description of the t_{2g}-orbitals in $[Co(OH_2)_6]^{3+}$ (a) bonding, (b) antibonding, or (c) nonbonding? Explain how you reached that conclusion.

16.70 Is the best description of the t_{2g}-orbitals in $[Fe(CN)_6]^{3-}$ (a) bonding, (b) antibonding, or (c) nonbonding? Explain how you reached that conclusion.

16.71 Is the best description of the e_g-orbitals in $[Fe(OH_2)_6]^{3+}$ (a) bonding, (b) antibonding, or (c) nonbonding? Explain how you reached that conclusion.

16.72 Is the best description of the t_{2g}-orbitals in $[CoF_6]^{3-}$ (a) bonding, (b) antibonding, or (c) nonbonding? Explain how you reached that conclusion.

16.73 Using concepts of ligand field theory, explain why water is a weaker field ligand than ammonia.

16.74 Using concepts of ligand field theory, explain why ethylenediamine is a weaker field ligand than CO.

Integrated Exercises

16.75 An analytical chemistry team analyzed a green mineral salt found in the glaze of an ancient pot. When they heated the mineral it gave off a colorless gas that turned limewater milky white. When they dissolved the mineral in sulfuric acid the same colorless gas was released and a blue solution formed. Suggest a possible formula for the compound and justify your conclusion.

16.76 An analytical chemistry team analyzed a yellow mineral salt found in the pigments in the studio of a Renaissance artist. When hydrochloric acid was added the mineral dissolved and formed an orange solution. The original salt was dissolved in water to form a yellow solution. When barium chloride was added to the solution a yellow solid formed. The solid was filtered and the water evaporated from the filtrate. The colorless chloride remaining was subjected to a flame test. It gave a bright yellow color to the flame. Suggest a possible formula for the compound and justify your conclusion.

16.77 Vanadium is used in steelmaking because it forms V_4C_3, which increases the strength of the steel and its resistance to wear. It is formed in the steel by adding V_2O_5 to iron ore as it is reduced by carbon during the refining process. (a) What is the likely oxidation state of vanadium in V_4C_3? (b) Write a balanced equation for the reaction of V_2O_5 with carbon to form V_4C_3 and CO_2.

16.78 When 5.25 g of $[Ni(OH_2)_x]Cl_2$ is heated, 2.387 g of water and 1.57 g of chlorine gas are collected. How many water molecules are present in the complex?

16.79 The compound $Cr(OH)_3$ is very insoluble in water; therefore, electrochemical methods must be used to determine its K_{sp}. Given that the reduction of $Cr(OH)_3(s)$ to Cr(s) and hydroxide ions has a standard potential of −1.34 V, calculate the solubility product for $Cr(OH)_3$.

16.80 The complex ion $[Ni(NH_3)_6]^{2+}$ forms in a solution containing 0.16 M $NH_3(aq)$ and 0.010 M $Ni^{2+}(aq)$. If the formation constant for $[Ni(NH_3)_6]^{2+}$ is 1.0×10^9, what are the equilibrium concentrations?

16.81 (a) Draw all the possible isomers of the square planar complex $[PtBrCl(NH_3)_2]$ and name each isomer. (b) How can the existence of these isomers be used to show that the complex is square planar rather than tetrahedral?

16.82 Draw the structures of all possible isomeric forms of $[CrBrClI(NH_3)_3]$. Which isomers are chiral?

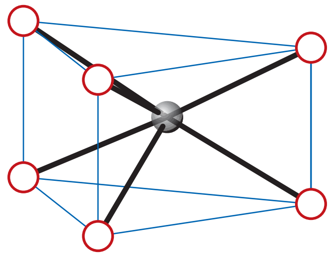
16.83 Suggest a chemical test for distinguishing between (a) $[Ni(SO_4)(en)_2]Cl_2$ and $[NiCl_2(en)_2]SO_4$; (b) $[NiI_2(en)_2]Cl_2$ and $[NiCl_2(en)_2]I_2$.

16.84 Trigonal bipyramidal complexes in which a metal ion is surrounded by five ligands are more rare than octahedral or tetrahedral complexes, but many are known. Will trigonal bipyramidal compounds of the formula MX_3Y_2 exhibit isomerism? If so what types of isomerism are possible?

16.85 (a) Sketch the orbital energy-level diagrams for $[MnCl_6]^{4-}$ and $[Mn(CN)_6]^{4-}$. (b) How many unpaired electrons are present in each complex? (c) Which complex absorbs the longer wavelengths of incident electromagnetic radiation? Explain your reasoning.

16.86 (a) Which types of ligands are π-acid ligands in general (see Exercise 16.67), strong-field or weak-field? (b) Which types of ligands are π-base ligands in general, strong-field or weak-field?

16.87 The trigonal prismatic structure shown in the illustration was once proposed for the $[CoCl_2(NH_3)_4]$ complex. Use the fact that only two isomers of the complex are known to rule out the prismatic structure.



16.88 A hexagonal planar structure was once proposed for the $[CrCl_3(NH_3)_3]$ complex. Use the fact that only two isomers of the complex are known to rule out the hexagonal planar structure.

16.89 Before the structures of octahedral complexes were determined, various means were used to explain the fact that d-metal ions could bind to a greater number of ligands than expected on the basis of their charges. For example, Co^{3+} can bind to six ligands, not just three. An early theory attempted to explain this behavior by postulating that once three ligands had attached to a metal ion of charge +3, the others bonded to the attached ligands, forming chains of ligands. Thus, the compound $[Co(NH_3)_6]Cl_3$, which we now know to have an octahedral structure, would have been described as $Co(NH_3—NH_3—Cl)_3$. Show how the chain theory is not consistent with at least two properties of coordination compounds.

16.90 How many chelate rings are present in: (a) $[Ru(ox)_3]^{3-}$; (b) $[Fe(trien)]^{3+}$ (trien is triethylenetetramine); (c) $[Cu(dien)_2]^{2+}$?

16.91 Suggest the form that the orbital energy-level diagram would take for a square planar complex with the ligands in the *xy* plane, and discuss how the building-up principle applies. *Hint:* The d_{z^2}-orbital has more electron density in the *xy* plane than the d_{zx}- or d_{yz}-orbitals but less than the d_{xy}-orbital.

16.92 Nickel(II) complexes with weak-field ligands such as the bromide ion have been found to be octahedral, but nickel(II) complexes with strong-field ligands have been found to be square planar. Explain these findings. (See Exercise 16.91.)

16.93 In a nickel-containing enzyme, various groups of atoms in the enzyme form a complex with the metal, which was found to be in the +2 oxidation state and to have no unpaired electrons. What is the most probable geometry of the Ni^{2+} complex: (a) octahedral; (b) tetrahedral; (c) square planar (see Exercise 16.91)? Justify your answer by drawing the orbital energy-level diagram of the ion.

16.94 Is there a correlation between the ligand field strength of the halide ions F^-, Cl^-, Br^-, and I^- and the electronegativity of the halogen? If so, can this correlation be explained by ligand field theory? Justify your answer.

16.95 The complexes $[Co(NH_3)_6]^{2+}$, $[Co(OH_2)_6]^{2+}$, and $[CoCl_4]^{2-}$ form colored solutions. One is pink, one yellow, and the third blue. Use the spectrochemical series and the relative magnitudes of Δ_O and Δ_T to match each color to a complex. Explain your reasoning.

16.96 Two chemists prepared a complex and determined its formula, which they wrote as $[CrCl_3NH_3]\cdot 2H_2O$. However, when they dissolved 2.11 g of the compound in water and added an excess of silver nitrate, 2.87 g of AgCl precipitated and they realized that the formula was incorrect. Write the correct formula of the compound and draw its structure, including all possible isomers.

16.97 A solid pink salt has the formula $CoCl_3\cdot 5NH_3\cdot H_2O$. When $AgNO_3$ is added to the pink solution containing 0.0010 mol of the salt, 0.43 g of AgCl precipitates. Heating the salt produces a purple solid with the formula $CoCl_3\cdot 5NH_3$. (a) Write the correct formula and name of the pink salt. (b) When $AgNO_3$ is added to a solution containing 0.0010 mol of the purple salt, 0.29 g of AgCl precipitates. Write the correct formula and name of the purple salt.

16.98 *cis*-Platin is an anticancer drug with a structure that can be viewed on the Web site. (a) What is the formula and systematic name for the compound *cis*-Platin? (b) Draw any isomers that are possible for this compound. Label any isomers that are optically active. (c) What is the coordination geometry of the platinum atom?

16.99 The Web site contains a molecular model of an iridium complex with formula $IrCl(CO)_2[P(C_6H_5)_3]_2$. (a) View this structure and determine the coordination geometry of the iridium atom. (b) What is the oxidation number of the iridium atom? (c) Are isomers of this compound possible? If so, draw them. Label any that are optical isomers.

16.100 Use the information in Appendix 2B to determine the equilibrium constant for the disproportionation of mercury(I) ions in aqueous solution at 25°C to mercury metal and mercury(II) ions.

16.101 Use the information in Appendix 2B to determine the equilibrium constant for the disproportionation of copper(I) ions in aqueous solution at 25°C to copper metal and copper(II) ions.

16.102 Ligand field theory predicts that different types of metal ions will form more stable complexes with certain types of ligands. From your understanding of ligand field theory, predict what types of ligands (weak-field or strong-field) would form the more stable complexes with the early transition metals in their highest oxidation states. Likewise, predict the types of ligands that would form the more stable complexes of the late transition metals (those to the right of the d-block) in their lowest oxidation states. Explain the reasoning behind your choices.

16.103 The concentration of Fe^{2+} ions in an acid solution can be determined by a redox titration with either $KMnO_4$ or $K_2Cr_2O_7$. The reduction products of these reactions are Mn^{2+} and Cr^{3+}, and in each case the iron is oxidized to Fe^{3+}. In one titration of an acidified Fe^{2+} solution, 25.20 mL of 0.0210 M $K_2Cr_2O_7(aq)$ was required for complete reaction. If the titration had been carried out with 0.0420 M $KMnO_4(aq)$, what volume of the permanganate solution would have been required for complete reaction?

Chemistry Connections

16.104 Hemoglobin contains one heme group per subunit. The heme group is an Fe^{2+} complex that is coordinated to the four N atoms in a porphyrin ligand in a square planar arrangement and to an N atom on the histidine residue (see Table 19.4) on the subunit. The hemoglobin molecule transports O_2 through the body by using a bond between O_2 and the Fe^{2+} ion at the center of the heme group. The Fe^{2+} ion can be viewed as having octahedral coordination, with one position unoccupied and available for bonding to oxygen. (See Box 16.1 and Section 10.13.)

(a) Draw the structure of the heme group with the sixth site not coordinated.

(b) The deoxygenated heme is a high-spin complex of the Fe^{2+} ion. When the oxygen molecule binds to the Fe^{2+} ion as the sixth ligand, the resulting octahedral complex is low-spin. Predict the number of unpaired electrons in (i) deoxygenated and (ii) oxygenated heme.

(c) Other compounds can bond to the iron atom, displacing oxygen. Identify which of the following species cannot bond to the iron in a heme group and explain your reasoning: CO; Cl^-; BF_3; NO_2^-.

(d) Hemoglobin in both its oxygenated (HbO_2) and deoxygenated (Hb) forms helps to maintain the pH of blood at an optimal level. Hemoglobin has several acidic protons, but the most important deprotonation is the first. At 25°C, for the deoxygenated form, $HbH(aq) + H_2O(l) \rightleftharpoons Hb^-(aq) + H_3O^+(aq)$ and $pK_{a1} = 6.62$. For the oxygenated form, $HbO_2H(aq) + H_2O(l) \rightleftharpoons HbO_2^-(aq) + H_3O^+(aq)$ and $pK_{a1} = 8.18$. Calculate the percentage of each form of hemoglobin that is deprotonated at the pH of blood, 7.4.

(e) Use your answer to part (d) to determine how the oxygenation of hemoglobin affects the pH of blood. That is, will the pH increase, decrease, or stay the same as more hemoglobin molecules become oxygenated? Explain your reasoning.

17.12 The Chemistry of Nuclear Power

What Are the Key Ideas? Changes in the nucleus of an atom can transform the atom into another element and result in the release of energy.

Why Do We Need to Know This Material? Nuclear chemistry is central to the development of nuclear energy. Chemistry provides techniques for preparing and recycling nuclear fuels and for the disposal of hazardous radioactive waste. Nuclear chemistry is used in medicine to treat cancer and to produce images of organs inside living bodies. It is used in chemistry to investigate reaction mechanisms and in archaeology to date ancient objects; nuclear chemistry is also part of the military strategies of many nations. Furthermore, this material informs the complex political, environmental, and economic debate about the deployment of nuclear energy.

What Do We Need to Know Already? Nuclear processes can be understood in terms of atomic structure (Section B and Chapter 1) and energy changes (Chapter 7). The section on rates of radioactive decay builds on chemical kinetics (particularly Sections 14.4 and 14.5).

When we study chemical reactions we treat the atomic nuclei as unchanging. However, nuclei can undergo changes, and **nuclear chemistry** explores the chemical consequences of those changes. One kind of change is **nuclear fission,** the fragmentation of large nuclei into smaller nuclei. Although fission is a source of energy, the resulting radioactive waste presents serious hazards to life. Another kind of change is **nuclear fusion,** the merging of small nuclei into larger ones. Fusion, too, is a source of energy, but the technique is technologically challenging and therefore expensive to develop. Nuclear processes are critical for the future of humanity, because they might prove to be the answer to one of our greatest challenges—the development of adequate energy supplies. The issues involved and chemistry's contributions to their solution are the subjects of this chapter.

This chapter has three main themes. First, we consider the pattern of nuclear stability and the manner in which unstable nuclei spontaneously undergo change. Changes in the composition of nuclei are the source of all the elements except hydrogen, and so we also discuss the origin of the elements. Next, we consider the effect of radiation on living beings and the uses to which nuclear radiation is put in chemistry. Finally, we consider nuclear energy and how chemistry is used to resolve the problems associated with its use.

NUCLEAR DECAY

Atomic nuclei are extraordinary particles. They contain all the protons in the atom crammed together in a tiny volume, despite their positive charges (Fig. 17.1). Yet most nuclei survive indefinitely despite the immense repulsive forces between their protons. In some nuclei, though, the repulsions that protons exert on one another overcome the force that holds the nucleons together. Fragments of the nucleus are then ejected, and the nucleus is said to "decay."

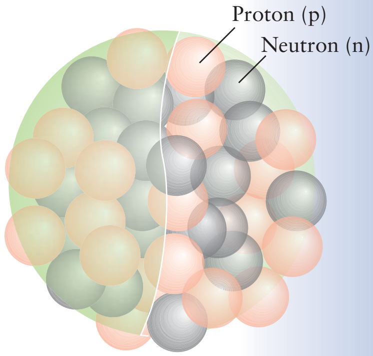

FIGURE 17.1 This illustration represents a nucleus as a collection of tightly bonded protons (pink) and neutrons (gray). The diameter of a nucleus is about 10 fm (1 fm = 10^{-15} m).

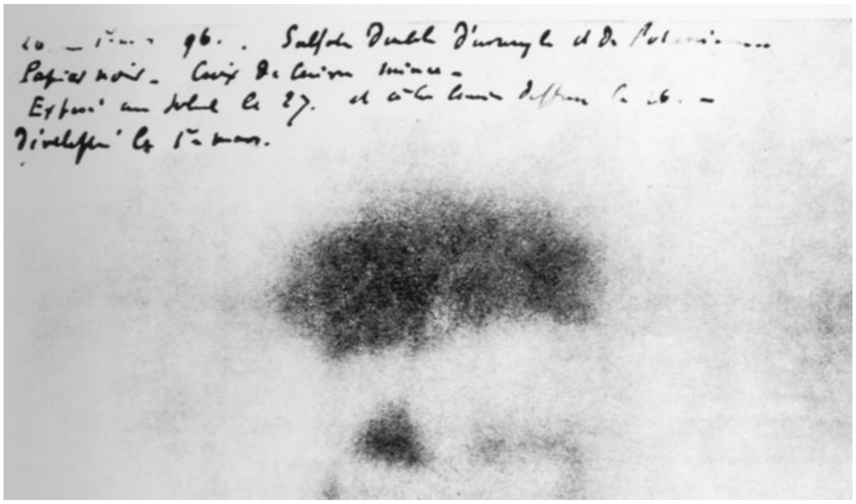

FIGURE 17.2 Henri Becquerel discovered radioactivity when he noticed that an unexposed photographic plate left near some uranium oxide became fogged. This photograph shows one of his original plates annotated with his record of the event.

FIGURE 17.3 Marie Sklodowska Curie (1867–1934).

17.1 The Evidence for Spontaneous Nuclear Decay

In 1896, the French scientist Henri Becquerel happened to store a lump of uranium oxide in a drawer that contained some photographic plates (Fig. 17.2). He was astonished to find that the plates had become darkened in certain areas even though they were covered with an opaque material. Becquerel realized that the uranium compound must give off some kind of radiation. Marie Sklodowska Curie (Fig. 17.3), a young Polish doctoral student, showed that the radiation, which she called **radioactivity,** was emitted by uranium regardless of the compound in which it was found. She concluded that the source must be the uranium atoms themselves. Together with her husband, Pierre, she went on to show that thorium, radium, and polonium are also radioactive.

The origin of the rays was initially a mystery, because the existence of the atomic nucleus was unknown at the time. However, in 1898, Ernest Rutherford took the first step to discover their origin when he identified three different types of radioactivity by observing the effect of electric fields on radioactive emissions (Fig. 17.4). Rutherford called the three types α (alpha), β (beta), and γ (gamma) radiation.

When Rutherford allowed the radiation to pass between two electrically charged electrodes, he found that one type was attracted to the negatively charged electrode. He proposed that the radiation attracted to the negative electrode consists of positively charged particles, which he called α **particles.** From the charge and mass of the particles, he was able to identify them as helium atoms that had lost their two electrons. Once Rutherford had identified the atomic nucleus (in 1908, Section B), he realized that an α particle must be a helium nucleus, He^{2+}. An α particle is denoted ${}^{4}_{2}\alpha$, or simply α. We can think of it as a tightly bound cluster of two protons and two neutrons (Fig. 17.5).

Rutherford found that a second type of radiation was attracted to the positively charged electrode. He proposed that this type of radiation consists of a stream of negatively charged particles. By measuring the charge and mass of these particles, he showed that they are electrons. The rapidly moving electrons emitted by nuclei are called β **particles** and denoted β^{-}. Because a β particle has no protons or neutrons, its mass number is 0 and it can be written ${}^{0}_{-1}e$.

A note on good practice: An electron emitted or captured by a nucleus does not have an atomic number, so its charge (-1) is written as a subscript preceding the symbol. We see later that this is a convenient bookkeeping device.

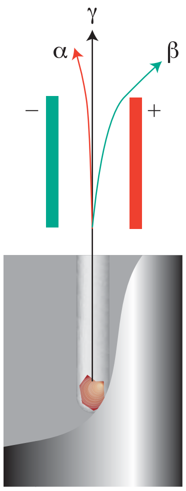

FIGURE 17.4 The effects of an electric field on nuclear radiation. The direction of deflection shows that α rays are positively charged, β rays negatively charged, and γ-rays uncharged.

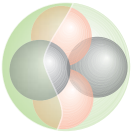

FIGURE 17.5 An α particle has two positive charges and a mass number of 4. It consists of two protons and two neutrons and is the same as the nucleus of a helium-4 atom.

The third common type of radiation that Rutherford identified, **γ radiation,** is not affected by an electrical field. Like light, γ radiation is electromagnetic radiation but of much higher frequency—greater than about 10^{20} Hz and corresponding to wavelengths less than about 1 pm. It can be regarded as a stream of very high energy photons, each photon being emitted by a single nucleus as that nucleus discards energy. The frequencies, ν, of γ-rays are related to the energy discarded by the nucleus, ΔE, by $\nu = \Delta E/h$ (see Section 1.4). The frequency is very high because the energy difference between the excited and the ground nuclear states is very large. Both α and β radiation are often accompanied by γ radiation: the new nucleus may be formed with its nucleons in a high-energy arrangement, and a γ-ray photon is emitted when nucleons settle down into a state of lower energy (Fig. 17.6).

Since Rutherford's work, scientists have identified other types of nuclear radiation. Some consist of rapidly moving particles, such as neutrons or protons. Others consist of rapidly moving **antiparticles,** particles with a mass equal to that of one of the subatomic particles but with an opposite charge. For example, the **positron** has the same mass as an electron but a positive charge; it is denoted β^+ or ${}^{0}_{+1}\text{e}$. When an antiparticle encounters its corresponding particle, both particles are annihilated and completely converted into energy. In **electron capture,** an electron in an atomic orbital is captured by the nucleus and a proton is converted into a neutron. Table 17.1 summarizes the properties of particles commonly found in nuclear radiation.

The most common types of radiation emitted by radioactive nuclei are α particles (the nuclei of helium atoms), β particles (fast electrons ejected from the nucleus), and γ-rays (high-frequency electromagnetic radiation).

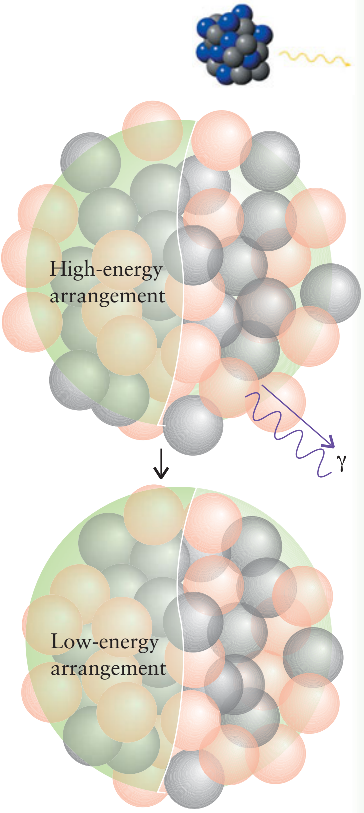

FIGURE 17.6 After a nucleus decays, the nucleons remaining in the nucleus may be left in a high-energy state, as shown by the expanded arrangement in the upper part of the illustration. As the nucleons adjust to a lower-energy arrangement (bottom), the excess energy is released as a γ-ray photon.

Animation 17.6

17.2 Nuclear Reactions

The discoveries of Becquerel, Curie, and Rutherford and Rutherford's later development of the nuclear model of the atom (Section B) showed that radioactivity is produced by **nuclear decay,** the partial breakup of a nucleus. The change in the composition of a nucleus is called a **nuclear reaction.** Recall from Section B that nuclei are composed of protons and neutrons that are collectively called *nucleons;* a specific nucleus with a given atomic number and mass number is called a **nuclide.** Thus, ${}^{1}\text{H}$, ${}^{2}\text{H}$, and ${}^{16}\text{O}$ are three different nuclides; the first two being isotopes of the same element. Nuclei that change

TABLE 17.1 Nuclear Radiation

Type	Degree of penetration	Speed*	Particle†	Mass number	Charge	Example
α	not penetrating but damaging	10% of c	helium-4 nucleus, ${}^{4}_{2}\text{He}^{2+}$, ${}^{4}_{2}\alpha$, α	4	+2	${}^{226}_{88}\text{Ra} \longrightarrow {}^{222}_{86}\text{Rn} + \alpha$ (Fig. 17.7)
β	moderately penetrating	<90% of c	electron, ${}^{0}_{-1}\text{e}$, β^-, β, e^-	0	−1	${}^{3}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{He} + {}^{0}_{-1}\text{e}$ (Fig. 17.8)
electron capture‡	—	—	electron, ${}^{0}_{-1}\text{e}$, e^-	0	−1	${}^{44}_{22}\text{Ti} + {}^{0}_{-1}\text{e} \longrightarrow {}^{44}_{21}\text{Sc}$ (Fig. 17.9)
γ	very penetrating; often accompanies other radiation	c	photon, γ	0	0	${}^{60}_{27}\text{Co}^{*\S} \longrightarrow {}^{60}_{27}\text{Co} + \gamma$ (Fig. 17.6)

*c is the speed of light.
†Alternative symbols are given for the particles; often it is sufficient to use the simplest (the one on the right).
‡Electron capture is not nuclear radiation but is included for completeness.
§An energetically excited state of a nucleus is usually denoted by an asterisk (*).

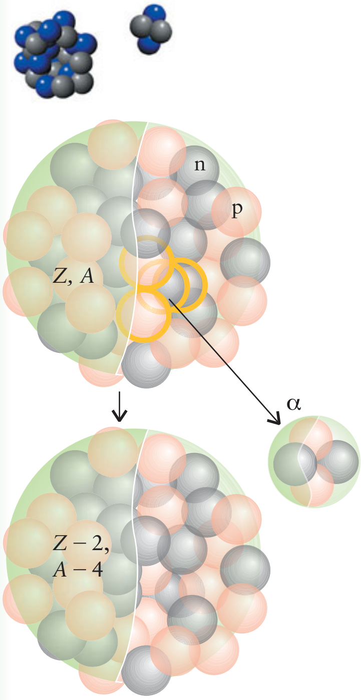

FIGURE 17.7 When a nucleus ejects an α particle, the atomic number of the nuclide decreases by 2 and the mass number decreases by 4. The nucleons ejected from the upper nucleus are indicated by the gold boundary.

Animation 17.7

their structure spontaneously and emit radiation are called **radioactive.** Often the result is a different nuclide.

Nuclear reactions differ in some important ways from chemical reactions. First, different isotopes of the same element undergo essentially the same chemical reactions, but their nuclei undergo very different nuclear reactions. Second, some nuclear reactions, such as those in which α or β particles are emitted from the nucleus, leave behind a nucleus with a different number of protons. The product, which is called the **daughter nucleus** (Fig. 17.7), is therefore the nucleus of an atom of a different element. For example, when a radon-222 nucleus emits an α particle, a polonium-218 nucleus is formed. In this case, a **nuclear transmutation,** the conversion of one element into another, has taken place. Another important difference between nuclear and chemical reactions is that energy changes are very much greater for nuclear reactions than for chemical reactions. For example, the combustion of 1.0 g of methane produces about 52 kJ of energy as heat. In contrast, a nuclear reaction of 1.0 g of uranium-235 produces about 8.2×10^7 kJ of energy, more than a million times as much.

To predict the identity of a daughter nucleus, we note how the atomic number and mass number change when the parent nucleus ejects a particle. For example, when a radium-226 nucleus, with $Z = 88$, undergoes α decay, it emits an α particle, which has a nuclear charge of +2 and a mass number of 4. Because both total mass number and total nuclear charge are conserved in a nuclear reaction, the fragment remaining must be a nucleus of atomic number 86 (radon) and mass number 222; so the daughter nucleus is radon-222:

$$^{226}_{88}\text{Ra} \longrightarrow {}^{222}_{86}\text{Rn} + {}^{4}_{2}\alpha$$

The expression for these changes is called a **nuclear equation.** The following examples show how to use nuclear equations to identify daughter nuclei.

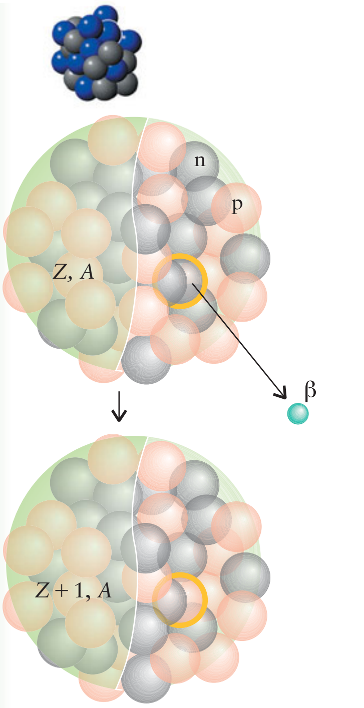

FIGURE 17.8 When a nucleus ejects a β particle, the atomic number of the nuclide increases by 1 and the mass number remains unchanged. The neutron that we can regard as the source of the electron is indicated by the gold boundary in the upper nucleus.

Animation 17.8

EXAMPLE 17.1 Predicting the outcome of α and β decay

What nuclide is produced by (a) α decay of polonium-211; (b) β decay of sodium-24?

Anticipate (a) In α decay, two protons and two neutrons are lost. As a result, we should expect the mass number to decrease by 4 and the atomic number to decrease by 2 (see Fig. 17.7). (b) The loss of one negative charge when an electron is ejected from the nucleus (Fig. 17.8) can be interpreted as the conversion of a neutron into a proton within the nucleus:

$$^{1}_{0}\text{n} \longrightarrow {}^{1}_{1}\text{p} + {}^{0}_{-1}\text{e}, \quad \text{or, more simply,} \quad \text{n} \longrightarrow \text{p} + \beta$$

We should expect the atomic number of the daughter nucleus to be greater by 1 than that of the parent nucleus, because it has one more proton, but the mass number to be unchanged, because the total number of nucleons in the nucleus should be the same.

PLAN Write the nuclear equation for each reaction, representing the daughter nuclide as E, with atomic number Z and mass number A. Then find Z and A from the requirement that both mass number and atomic number are conserved in a nuclear reaction.

SOLVE

(a) Write the equation for the nuclear reaction.

$$^{211}_{84}\text{Po} \longrightarrow {}^{A}_{Z}\text{E} + {}^{4}_{2}\alpha$$

Express mass and charge conservation.

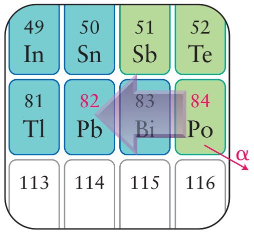
$$211 = A + 4, \text{ or } A = 207$$
$$84 = Z + 2, Z = 82$$

Identify the element.

$Z = 82$ corresponds to Pb.

Write the nuclear equation.

$^{211}_{84}Po \longrightarrow {}^{207}_{82}Pb + {}^{4}_{2}\alpha$



(b) Write the equation for the nuclear reaction.

$^{24}_{11}Na \longrightarrow {}^{A}_{Z}E + {}^{0}_{-1}e$

Express mass and charge conservation.

$24 = A + 0$, or $A = 24$, unchanged

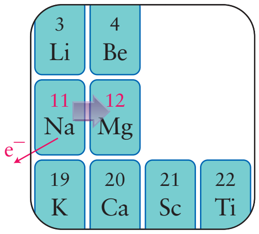
$11 = Z - 1$, $Z = 12$

Identify the element.

$Z = 12$ corresponds to Mg

Write the equation for the nuclear reaction.

$^{24}_{11}Na \longrightarrow {}^{24}_{12}Mg + {}^{0}_{-1}e$



Evaluate As expected, the α decay resulted in a nuclide having two fewer protons and two fewer neutrons; the β decay produced a nuclide in which a proton was converted into a neutron, so there was no change in mass.

Self-Test 17.1A Identify the nuclide produced by (a) α decay of uranium-235, (b) β decay of lithium-9.

[***Answer:*** (a) Thorium-231; (b) beryllium-9]

Self-Test 17.1B Identify the nuclide produced by (a) α decay of thorium-232, (b) β decay of radium-228.

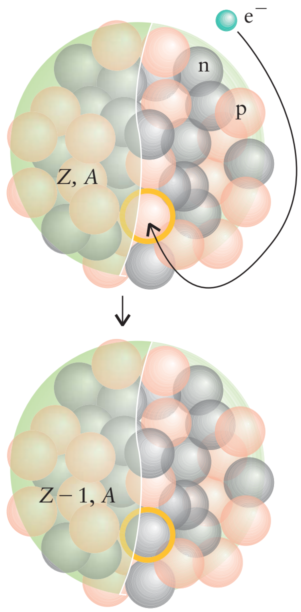


FIGURE 17.9 In electron capture, a nucleus captures one of the surrounding electrons. The effect is to convert a proton (outlined in gold) into a neutron (outlined in gold). As a result, the atomic number of the nuclide decreases by 1 but the mass number remains the same.

EXAMPLE 17.2 Predicting the outcome of electron capture and positron emission

What nuclide is produced when (a) calcium-41 undergoes electron capture; (b) oxygen-15 undergoes positron emission?

Anticipate (a) In electron capture, a proton is turned into a neutron and, although there is no change in mass number, the atomic number should be reduced by 1 (Fig. 17.9). (b) A positron has the same tiny mass as an electron but a single positive charge. Positron emission can be thought of as the positive charge shrugged off by a proton as it is converted into a neutron. As a result, the atomic number decreases by 1 but there should be no change in mass number (Fig. 17.10).

PLAN Write the nuclear equation for each reaction, representing the daughter nuclide as E, with atomic number Z and mass number A. Then find Z and A from the requirement that both mass number and atomic number are conserved in a nuclear reaction.

SOLVE

(a) Write the equation for the nuclear reaction.

$^{41}_{20}Ca + {}^{0}_{-1}e \longrightarrow {}^{A}_{Z}E$

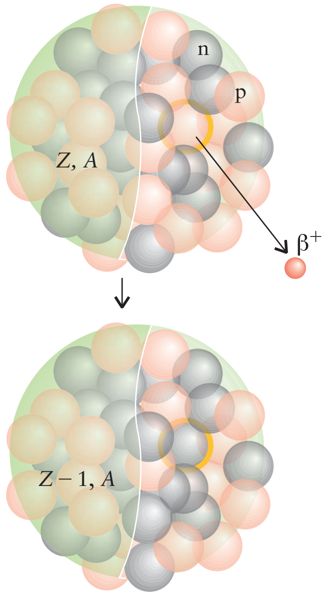

FIGURE 17.10 In positron (β^+) emission, the nucleus ejects a positron. The effect is to convert a proton into a neutron. As a result, the atomic number of the nuclide decreases by 1 but the mass number remains the same.

Express mass and charge conservation.

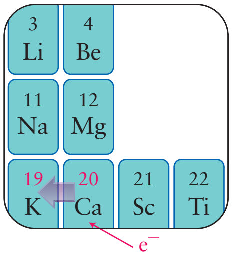
$41 + 0 = A$, or $A = 41$, unchanged
$20 - 1 = Z$, $Z = 19$

Identify the element.

$Z = 19$ corresponds to K.

Write the nuclear equation.

$${}^{41}_{20}\text{Ca} + {}^{0}_{-1}\text{e} \longrightarrow {}^{41}_{19}\text{K}$$



(b) Write the equation for the nuclear reaction.

$${}^{15}_{8}\text{O} \longrightarrow {}^{A}_{Z}\text{E} + {}^{0}_{+1}\text{e}$$

Express mass and charge conservation.

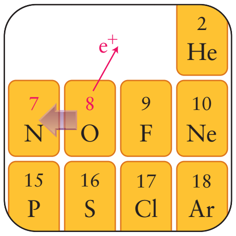
$15 = A + 0$, or $A = 15$, unchanged
$8 = Z + 1$, $Z = 7$

Identify the element.

$Z = 7$ corresponds to N.

Write the nuclear equation.

$${}^{15}_{8}\text{O} \longrightarrow {}^{15}_{7}\text{N} + {}^{0}_{+1}\text{e}$$



Evaluate As expected, in both electron capture and positron emission a proton has been converted into a neutron, so there was a decrease in atomic number but no change in mass.

Self-Test 17.2A Identify the nuclide produced and write the nuclear equation for (a) electron capture by beryllium-7; (b) positron emission by sodium-22.

[***Answer:*** (a) ${}^{7}_{4}\text{Be} + {}^{0}_{-1}\text{e} \longrightarrow {}^{7}_{3}\text{Li}$; (b) ${}^{22}_{11}\text{Na} \longrightarrow {}^{22}_{10}\text{Ne} + {}^{0}_{+1}\text{e}$]

Self-Test 17.2B Identify the nuclide produced and write the nuclear equation for (a) electron capture by iron-55; (b) positron emission by carbon-11.

Nuclear reactions may result in the formation of different elements. The transmutation of a nucleus can be predicted by noting the atomic numbers and the mass numbers in the nuclear equation for the process.

17.3 The Pattern of Nuclear Stability

The nuclei of some elements are stable, but others decay the moment they are formed. It would be useful to know if there is a pattern to the stabilities and instabilities of nuclei, because such a pattern would allow us to make predictions about the modes of nuclear decay. One clue is that elements with even atomic numbers are consistently more abundant than neighboring elements with odd atomic numbers. We can see this difference in Fig. 17.11, which is a plot of the cosmic abundance of the elements against atomic number. The same pattern occurs on Earth. Of the eight elements present as 1% or more of the mass of the Earth, only one, aluminum, has an odd atomic number.

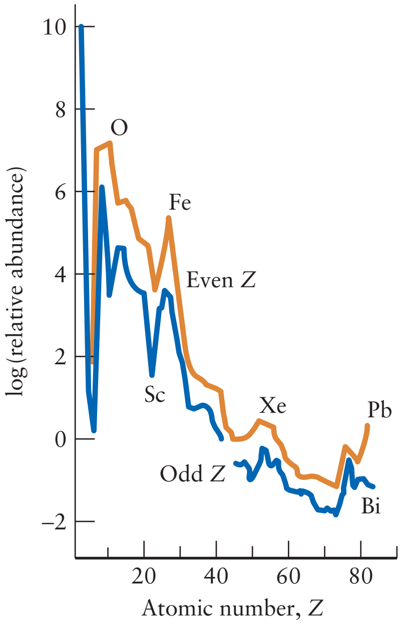


FIGURE 17.11 The variation in cosmic nuclear abundance with atomic number. Note that elements with even atomic numbers (brown curve) are consistently more abundant than neighboring elements with odd atomic numbers (blue curve).

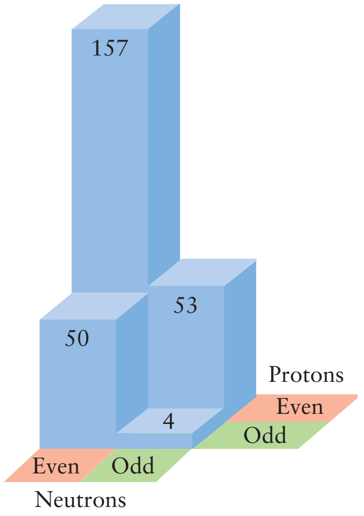

FIGURE 17.12 The numbers of stable nuclides having even or odd numbers of neutrons and protons. With the exception of hydrogen, by far the greatest number of stable nuclides (157) have even numbers of both protons and neutrons. Only four stable nuclides have odd numbers of both protons and neutrons.

Nuclei with even numbers of both protons and neutrons are more stable than those with any other combination. Conversely, nuclei with odd numbers of both protons and neutrons are the least stable (Fig. 17.12). Nuclei are more likely to be stable if they are built from certain numbers of either kind of nucleons. These numbers—namely, 2, 8, 20, 50, 82, 114, 126, and 184—are called **magic numbers.** For example, there are ten stable isotopes of tin ($Z = 50$), the most of any element, but only two stable isotopes of its neighbor antimony ($Z = 51$). The α particle itself is a "doubly magic" nucleus, with two protons and two neutrons. We shall see later that a number of actinoids decay through a series of steps until they reach Pb, another doubly magic nuclide, with 126 neutrons and 82 protons. This pattern of nuclear stability is similar to the pattern of electron stability in atoms: the noble gas atoms have 2, 10, 18, 36, 54, and 86 electrons.

Figure 17.13 is a plot of mass number against atomic number for known nuclides. Stable nuclei are found in a **band of stability** surrounded by a **sea of instability,** the region of unstable nuclides that decay with the emission of radiation. For atomic numbers up to about 20, the stable nuclides have approximately equal numbers of neutrons and protons, and so A is close to $2Z$. For higher atomic numbers, all known nuclides—both stable and unstable—have more neutrons than protons, and so $A > 2Z$.

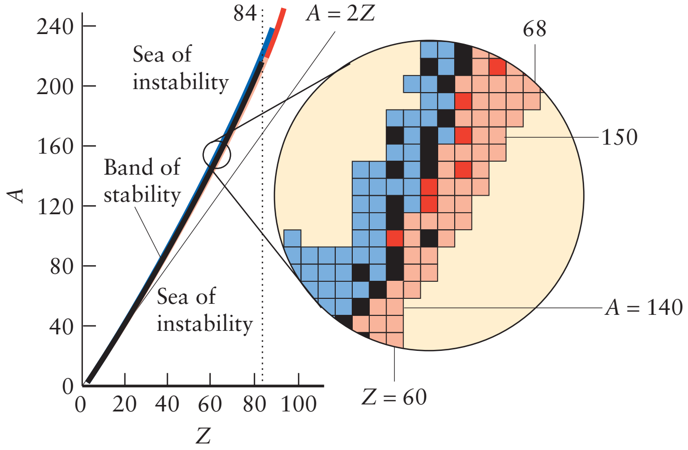

FIGURE 17.13 The manner in which nuclear stability depends on the atomic number and the mass number. Nuclides along the narrow black band (the band of stability) are generally stable. Nuclides in the blue region are likely to emit a β particle, and those in the red region are likely to emit an α particle. Nuclei in the pink region are likely either to emit positrons or to undergo electron capture. The straight line indicates the position that nuclides would have if the numbers of neutrons and protons were equal ($A = 2Z$). The inset shows a magnified view of the diagram near $Z = 60$.

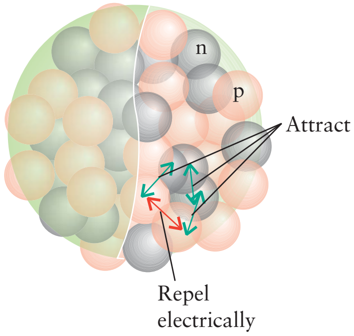

FIGURE 17.14 The protons in a nucleus repel one another electrically, but the strong force, which acts between all nucleons, holds the nucleus together.

The increase in the ratio of neutrons to protons with increasing atomic number can be explained by considering the role of the neutrons in helping to overcome the electrical repulsions between protons. The **strong force** that holds the protons and neutrons together in a nucleus is powerful enough to overcome the electrostatic repulsion between the protons, but it can act over only a very short distance—about the diameter of a nucleus (Fig. 17.14). Because neutrons are uncharged, they can contribute to the strong force without adding to the electrostatic repulsion. A lot of neutrons are needed to overcome the mutual repulsion of the protons in a nucleus of high atomic number, which explains why the band of stability curves upward.

Nuclei with certain even numbers of protons and of neutrons are the most stable.

17.4 Predicting the Type of Nuclear Decay

We can use Fig. 17.13 to predict the type of disintegration that a radioactive nuclide is likely to undergo. Nuclei that lie above the band of stability are **neutron rich:** they have a high proportion of neutrons. These nuclei tend to decay in such a way that the final n/p ratio is closer to that found in the band of stability. For example, a ${}^{14}_{6}C$ nucleus can reach a more stable state by ejecting a β particle, which reduces the n/p ratio as a result of the conversion of a neutron into a proton (Fig. 17.15):

$${}^{14}_{6}C \longrightarrow {}^{14}_{7}N + {}^{0}_{-1}e$$

Nuclides that lie below the band of stability have a low proportion of neutrons and are classified as **proton rich.** These isotopes tend to decay in such a way that the atomic number is reduced. For example, proton-rich ${}^{29}_{15}P$ is radioactive and decays by emitting a positron, a process that converts a proton into a neutron and raises the final n/p ratio:

$${}^{29}_{15}P \longrightarrow {}^{29}_{14}S + {}^{0}_{+1}e$$

As shown in Example 17.2, electron capture and proton emission also decrease the proton count of proton-rich nuclides.

Bismuth ($Z = 83$) was thought to have a stable isotope, but in 2005 even that isotope was found to decay extremely slowly.

Very few nuclides with $Z < 60$ emit α particles. All nuclei with $Z > 82$ are unstable and decay mainly by α-particle emission. They must discard protons to reduce their atomic number and generally need to lose neutrons, too. These nuclei decay in a step-by-step manner and give rise to a **radioactive series,** a characteristic sequence of nuclides (Fig. 17.16). First, one α particle is ejected, then another α particle or a β particle is ejected, and so on, until a stable nucleus, such as an isotope of lead (with the magic atomic number 82) is formed. For example, the uranium-238 series ends at lead-206, the uranium-235 series ends at lead-207, and the thorium-232 series ends at lead-208.

Self-Test 17.3A Which of the following processes, (a) electron capture, (b) proton emission, (c) β^- emission, (d) β^+ emission, might a ${}^{145}_{64}Gd$ nucleus undergo to begin to reach stability? Refer to Figs. 17.13 and 17.15.

[***Answer:*** a, b, d]

Self-Test 17.3B Which of the set of processes listed in Self-Test 17.3A might a ${}^{148}_{58}Ce$ nucleus undergo to begin to reach stability?

The pattern of nuclear stability can be used to predict the likely mode of radioactive decay: neutron-rich nuclei tend to reduce their neutron count; proton-rich nuclei tend to reduce their proton count. In general, only heavy nuclides emit α particles.

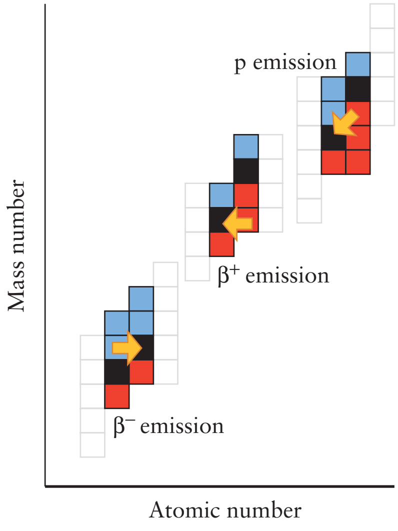

FIGURE 17.15 Three different ways of reaching the band of stability (black). Nuclei that are neutron rich (blue region) tend to convert neutrons into protons by β emission; nuclei that are proton rich (red) tend to reach stability (black) by emitting a positron, capturing an electron, or emitting a proton.

17.5 Nucleosynthesis

In order to study some nuclear processes, scientists may need to create certain nuclides that might not exist naturally. For example, ${}^{11}_{3}Li$ is an unstable nuclide that has so many neutrons that the strong force allows its nucleus to expand about 10 times, to nearly the size of a radium nucleus. Such a nuclide can provide valuable information for nuclear theorists, but it must be synthesized, as it does not occur naturally. The process of forming elements is **nucleosynthesis.** This process occurs naturally. Hydrogen and helium were produced in the Big Bang; all other naturally occurring elements are descended from these two, as a

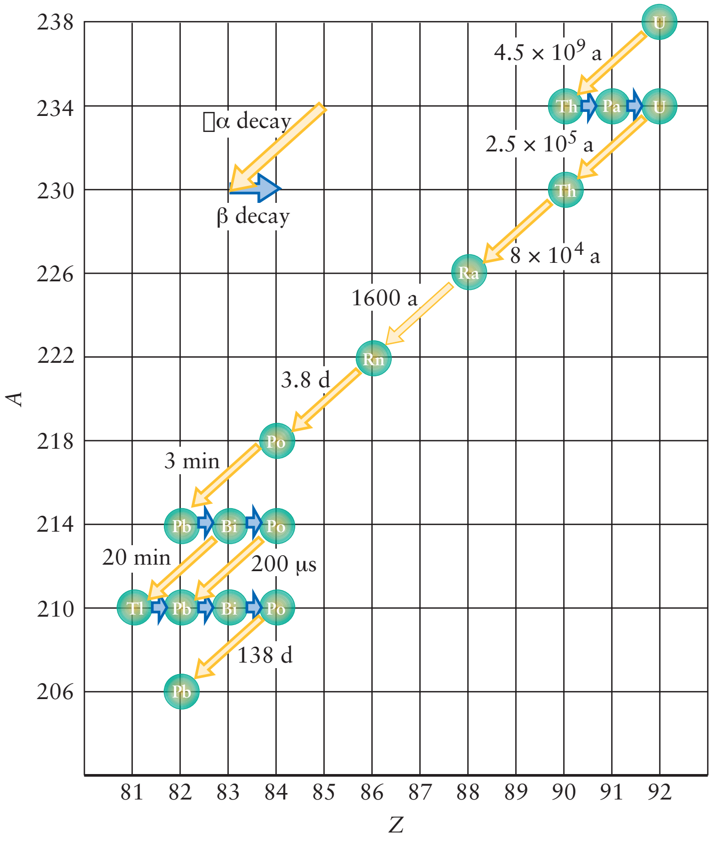

FIGURE 17.16 The uranium-238 decay series. The times are the half-lives of the nuclides (see Section 17.7). The unit a, for annum, is the SI abbreviation for year.

result of nuclear reactions taking place either in stars or in space. Some elements—among them technetium and promethium—are found in only trace amounts on Earth. Although these elements were made in stars, their short lifetimes did not allow them to survive long enough to contribute to the formation of our planet. However, nuclides that are too unstable to be found on Earth can be made by artificial techniques, and scientists have added about 2700 different nuclides to the approximately 270 that occur naturally.

To overcome the energy barriers to nuclear synthesis, particles must collide vigorously with one another (Fig. 17.17), as they do in the hot interiors of stars. Therefore, to make elements artificially, we need to simulate the conditions found inside a star. If it is traveling fast enough, a proton, an α particle, or another positively charged nucleus has enough kinetic energy to overcome the electrostatic repulsion from the nucleus. The incoming particle penetrates into the nucleus, where it is captured by the strong force. The high speeds required can be achieved in a particle accelerator.

The **transmutation** of elements—the conversion of one element into another, particularly of lead into gold—was the dream of the alchemists and one of the roots of modern chemistry. However, the alchemists had access only to chemical techniques, which proved ineffective because they involved energy changes far too weak to force nucleons into nuclei. Transmutation has now been recognized in nature and achieved in the laboratory, but by using methods undreamed of by the early alchemists. Rutherford achieved the first artificial nuclear transmutation in 1919. He bombarded nitrogen-14 nuclei with high-speed α particles. The products of the transmutation were oxygen-17 and a proton:

$$^{14}_{7}\text{N} + {}^{4}_{2}\alpha \longrightarrow {}^{17}_{8}\text{O} + {}^{1}_{1}\text{p}$$

Such transmutation processes are commonly written simply as

$$^{14}_{7}\text{N}(\alpha, \text{p})^{17}_{8}\text{O}$$

or, in general,

Target(incoming particle, ejected particle)product

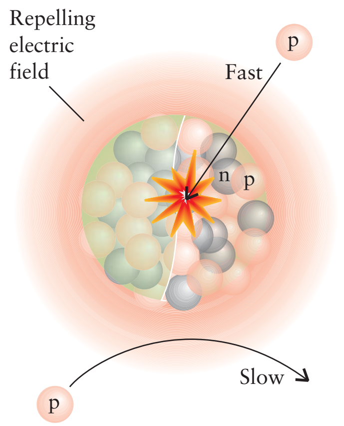

FIGURE 17.17 When a positively charged particle approaches a nucleus, it is repelled strongly. However, a very fast particle can reach the nucleus before the repulsion turns it aside, and a nuclear reaction may result.

A large number of nuclides have been synthesized on Earth. For instance, technetium was prepared (as technetium-97) for the first time on Earth in 1937 by the reaction between molybdenum and deuterium nuclei:

$$^{97}_{42}\text{Mo} + ^{2}_{1}\text{H} \longrightarrow ^{97}_{43}\text{Tc} + 2\,^{1}_{0}\text{n}, \quad \text{or} \quad ^{97}_{42}\text{Mo(d, 2n)}^{97}_{43}\text{Tc}$$

where d denotes a deuteron, $^{2}\text{H}^{+}$. Technetium is now moderately abundant because it accumulates in the decay products of nuclear power plants. Another isotope, technetium-99, has pharmaceutical applications, particularly for bone scans (Box 17.1).

BOX 17.1 WHAT HAS THIS TO DO WITH . . . STAYING ALIVE?

Nuclear Medicine

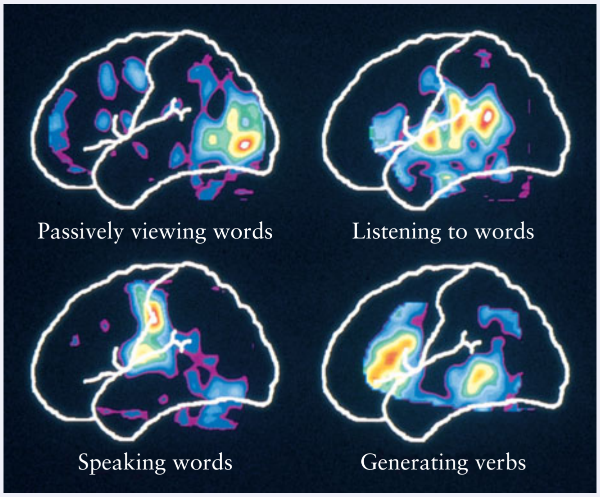
Nuclear chemistry has transformed medical diagnosis, treatment, and research. Radioactive tracers are used to measure organ function, sodium-24 to monitor blood flow, and strontium-87 to study bone growth. However, the most dramatic effect of radioisotopes on diagnosis has been in the field of imaging. Technetium-99m (see Exercise 17.48; the m denotes a "metastable," reasonably long-lived, state) is the most widely used radioactive nuclide in medicine, especially for bone scans. This isotope is highly active and gives off γ-rays that pass through the body. The γ-rays cause much less damage than α particles would, and the isotope is so short-lived that the risk to the patient is minimal.

Cobalt-60 is used for the *gamma knife*, a technique that is actually knife-less and that can destroy tumors in locations such as the brain when surgery is not possible. In gamma-knife therapy, about 200 γ rays are focused from different angles onto a tumor with a known location. Each γ-ray by itself has a low amplitude and so causes little or no damage to the tissues through which it passes. However, at the intersection of 200 of these energetic rays, the radiation is very strong and sufficiently powerful to destroy the tumor cells. The process is painless and the patient can remain awake through the treatment. The patient's head does not need to be shaved and recovery time is short.

Positron emission tomography (PET) makes use of a short-lived positron emitter such as fluorine-18 to image human tissue with a degree of detail not possible with x-rays. It has been used extensively to study brain function (see illustrations) and in medical diagnosis. For example, when the hormone estrogen is labelled with fluorine-18 and injected into a cancer patient, the fluorine-bearing compound is preferentially absorbed by the tumor. The positrons given off by the fluorine atoms are quickly annihilated when they meet electrons. The resulting γ-rays are detected by a scanner that moves slowly over the part of the body containing the tumor. The growth of the tumor can be estimated quickly and accurately with this technique. A PET imaging facility must be located near a cyclotron so that the positron emitters can be incorporated into the desired compounds as soon as they are created.

Several kinds of cancer therapy use radiation to destroy malignant cells. *Boron neutron capture therapy* is unusual in that boron-10, the isotope injected, is not radioactive. However, when boron-10 is bombarded with neutrons, it gives off highly destructive α particles. In boron neutron capture therapy, the boron-10 is incorporated into a compound that is preferentially absorbed by tumors. The patient is then exposed to brief periods of neutron bombardment. As soon as the bombardment ceases, the boron-10 stops generating α particles.

This patient is about to undergo a PET scan of brain function.



These four PET scans show how blood flow to different parts of the brain is affected by various activities. In this case, an oxygen isotope that is taken up by the hemoglobin in blood is used as a source of positrons.

A neutron can get close to a target nucleus more easily than a proton can. Because a neutron has no charge and hence is not repelled by the nuclear charge, it need not be accelerated to such high speeds. An example of **neutron-induced transmutation** is the formation of cobalt-60, which is used in the radiation treatment of cancer. The three-step process starts from iron-58. First, iron-59 is produced:

$$^{58}_{26}\mathrm{Fe} + {}^{1}_{0}\mathrm{n} \longrightarrow {}^{59}_{26}\mathrm{Fe}$$

The second step is the β decay of iron-59 to cobalt-59:

$$^{59}_{26}\mathrm{Fe} \longrightarrow {}^{59}_{27}\mathrm{Co} + {}^{0}_{-1}\mathrm{e}$$

In the final step, cobalt-59 absorbs another neutron from the incident neutron beam and is converted into cobalt-60:

$$^{59}_{27}\mathrm{Co} + {}^{1}_{0}\mathrm{n} \longrightarrow {}^{60}_{27}\mathrm{Co}$$

The overall reaction is

$$^{58}_{26}\mathrm{Fe} + 2\,{}^{1}_{0}\mathrm{n} \longrightarrow {}^{60}_{27}\mathrm{Co} + {}^{0}_{-1}\mathrm{e}, \quad \text{or} \quad {}^{58}_{26}\mathrm{Fe}(2\mathrm{n}, \beta^-){}^{60}_{27}\mathrm{Co}$$

Self-Test 17.4A Complete the following nuclear reactions: (a) ? + $^{4}_{2}\alpha \longrightarrow {}^{243}_{96}\mathrm{Cm} + {}^{1}_{0}\mathrm{n}$; (b) $^{242}_{96}\mathrm{Cm} + {}^{4}_{2}\alpha \longrightarrow {}^{245}_{98}\mathrm{Cf}$ + ?.

[***Answer:*** (a) $^{240}_{94}\mathrm{Pu}$; (b) $^{1}_{0}\mathrm{n}$]

Self-Test 17.4B Complete the following nuclear reactions: (a) $^{250}_{98}\mathrm{Cf}$ + ? $\longrightarrow {}^{257}_{103}\mathrm{Lr} + 4\,{}^{1}_{0}\mathrm{n}$; (b) ? + $^{12}_{6}\mathrm{C} \longrightarrow {}^{254}_{102}\mathrm{No} + 4\,{}^{1}_{0}\mathrm{n}$.

The **transuranium elements** are the elements following uranium in the periodic table. The elements from rutherfordium (Rf, Z = 104) through meitnerium (Mt, Z = 109) were formally named in 1997. The **transmeitnerium elements,** the elements beyond meitnerium (including hypothetical nuclides that have not yet been made) are named systematically, at least until they have been identified and there is international agreement on a permanent name. Their systematic names use the prefixes in Table 17.2, which identify their atomic numbers, with the ending *-ium*. Thus, element 110 was known as ununnilium until it was named darmstadtium (Ds) in 2003.

New elements and isotopes of known elements are made by nucleosynthesis; the repulsive electrical forces of like-charged particles are overcome when very fast particles collide.

TABLE 17.2 Notation for the Systematic Nomenclature of Elements*

Digit	Prefix	Abbreviation
0	nil	n
1	un	u
2	bi	b
3	tri	t
4	quad	q
5	pent	p
6	hex	h
7	sep	s
8	oct	o
9	enn	e

*For instance, element 123 would be named unbitriium, Ubt.

NUCLEAR RADIATION

Nuclear radiation is sometimes called **ionizing radiation,** because it is energetic enough to eject electrons from atoms. Hospitals use nuclear radiation to kill unwanted tissue, such as cancerous cells (see Box 17.1). Yet the same powerful effects that help to diagnose and cure illness can also damage healthy tissue. The damage depends on the strength of the source, the type of radiation, and the length of exposure. The three principal types of nuclear radiation have different abilities to penetrate matter (Table 17.3).

17.6 The Biological Effects of Radiation

Relatively massive, highly charged α particles interact so strongly with matter that they slow down, capture electrons from surrounding matter, and change into bulky helium atoms before traveling very far. They penetrate only the first layer of skin and can be stopped by glass, by clothing, even by a sheet of paper. Most α radiation is absorbed by the surface layer of dead skin, where it can do little harm. However, α particles can

TABLE 17.3 Shielding Requirements of α, β, and γ Radiation

Radiation	Relative penetrating power	Shielding required
α	1	paper, skin
β	100	3 mm aluminum
γ	10 000	concrete, lead

be extremely dangerous if inhaled or ingested. The energy of their impact can knock atoms out of molecules, which can lead to serious illness and death. For example, plutonium, considered to be one of the most toxic radioactive materials, is an α emitter and can be handled safely with minimal shielding. However, it is easily oxidized to Pu^{4+}, which has chemical properties similar to those of Fe^{3+}. Plutonium can take the place of iron in the body and become absorbed into bone, where it destroys the body's ability to produce red blood cells. The result is radiation sickness, cancer, and death.

Second in penetrating power is β radiation. These fast electrons can penetrate about 1 cm into flesh before their electrostatic interactions with the electrons and nuclei of molecules bring them to a standstill.

Most penetrating of all is γ radiation. The high-energy γ-ray photons can pass right through buildings and bodies and can cause damage by ionizing the molecules in their path. Protein molecules and DNA that have been damaged in this way can no longer function, and the result can be radiation sickness and cancer. Intense sources of γ-rays must be surrounded by shields built from lead bricks or thick concrete to absorb this penetrating radiation.

The **absorbed dose** of radiation is the energy deposited in a sample (in particular, the human body) when it is exposed to radiation. The SI unit of absorbed dose is the **gray,** Gy, which corresponds to an energy deposit of $1\ J\cdot kg^{-1}$. The original unit used for reporting dose was the **radiation absorbed dose** (rad), the amount of radiation that deposits 10^{-2} J of energy per kilogram of tissue, and so 1 rad = 10^{-2} Gy. A dose of 1 rad corresponds to a 65-kg person absorbing a total of 0.65 J, which is not very much energy: it is enough to boil only 0.2 mg of water. However, the energy of a particle of nuclear radiation is highly localized, like the impact of a subatomic bullet. As a result, the incoming particles can break individual bonds as they collide with molecules in their path.

The extent of radiation damage to living tissue depends on the type of radiation and the type of tissue. We must therefore include the **relative biological effectiveness,** Q, when assessing the damage that a given dose of each type of radiation may cause. For β and γ radiation, Q is set arbitrarily at about 1; but, for α radiation, Q is close to 20. A dose of 1 Gy of γ radiation causes about the same amount of damage as 1 Gy of β radiation, but 1 Gy of α particles is about 20 times as damaging (even though these particles are the least penetrating). The precise figures depend on the total dose, the rate at which the dose accumulates, and the type of tissue, but these values are typical.

The **dose equivalent** is the actual dose modified to take into account the different destructive powers of the various types of radiation in combination with various types of tissue. It is obtained by multiplying the actual dose (in gray) by the value of Q for the radiation type. The result is expressed in the SI unit called a **sievert** (Sv):

$$\text{Dose equivalent (Sv)} = Q \times \text{absorbed dose (Gy)} \qquad \mathbf{(1)}$$

The former (non-SI) unit of dose equivalent was the **roentgen equivalent man** (rem), which was defined in the same way as the sievert but with the absorbed dose in rad; thus, 1 rem = 10^{-2} Sv.

A dose of 0.3 Gy (30 rad) of γ radiation corresponds to a dose equivalent of 0.3 Sv (30 rem), enough to cause a reduction in the number of white blood cells (the cells that fight infection), but 0.3 Gy of α radiation corresponds to 6 Sv (600 rem), which is enough to cause death if an α emitter is ingested or inhaled. A typical average annual dose equivalent that we each receive from natural sources, called **background radiation,** is about $2\ mSv\cdot a^{-1}$ (where a, for annum, is the SI abbreviation for year), but this figure varies, depending on our life style and where we live. About 20% of background radiation comes from our own bodies. About 30% comes from cosmic rays (a mix of γ-rays and high-energy subatomic particles from outer space) that continuously bombard the Earth, and 40% comes from radon seeping out of the ground. The remaining 10% is a result largely of medical diagnoses (a typical chest x-ray gives a dose equivalent of about 0.07 mSv). Emissions from nuclear power plants and other nuclear facilities contribute about 0.1% in countries where they are widely used.

The principal source of radioactivity in the human body is potassium-40. About 35 000 potassium-40 nuclei disintegrated in your body while you were reading this sentence.

Human exposure to radiation is monitored by reporting the absorbed dose and the dose equivalent; the latter takes into account the effects of different types of radiation on tissues.

BOX 17.2 HOW DO WE KNOW . . . HOW RADIOACTIVE A MATERIAL IS?

The ability of nuclear radiation to eject electrons from atoms and ions can be used to measure its intensity. Becquerel first gauged the intensity of radiation by determining the degree to which it blackened a photographic film. The blackening results from the same redox processes as those of ordinary photography, such as

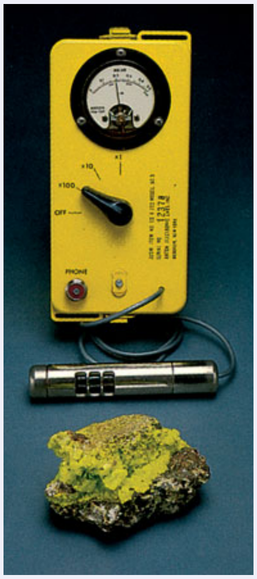
$$Ag^{+} + Br^{-} \xrightarrow{\text{light}} Ag + Br$$

except that the initial oxidation of the bromide ions is caused by nuclear radiation instead of light. Becquerel's technique is still used in film badges, which monitor the exposure of workers to radiation.

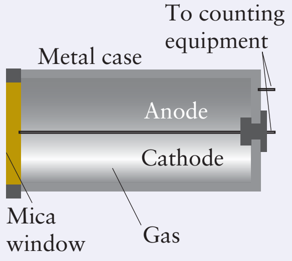
A *Geiger counter* monitors radiation by detecting the ionization of a low-pressure gas, as shown in the illustration. The radiation ionizes atoms of the gas inside a cylinder and allows a brief flow of current between the electrodes. The resulting electrical signal can be recorded directly or converted into an audible click. The frequency of the clicks indicates the intensity of the radiation. A limitation of Geiger counters is that they do not respond well to γ-rays. Only about 1% of the γ-ray photons are detected, whereas all the β particles incident on the counter are detected. Because the efficiency of a Geiger counter depends on the size of the tube, a counter used to monitor a wide range of activities usually contains two tubes of different sizes.

A *scintillation counter* makes use of the fact that phosphors—phosphorescent substances such as sodium iodide and zinc sulfide (Section 6.15)—give a flash of light—a scintillation—when exposed to radiation. The counter also contains a photomultiplier tube, which converts light into an electrical signal. The intensity of the radiation is determined from the strength of the electronic signal.

A *dosimeter* is used to collect cumulative evidence of exposure to radiation and is worn as a badge. Dosimeters contain a thermoluminescent material such as lithium fluoride. Any incident radiation knocks electrons out of the fluoride ions. The electrons migrate away from the fluorine atoms but are trapped in the crystal. When the crystal is heated, they fall back into the fluorine atoms and give off the difference in energy as light. The dose of radiation received is determined by the intensity of the light. Dosimeters can be used over a period of time ranging from one day to several weeks, because the excited electrons accumulate with continued exposure, allowing a long-term dosage to be evaluated.



(a)



(b)

(a) A Geiger counter with a piece of uranium ore. (b) The detector in a Geiger counter contains a gas (often either argon and a little ethanol vapor or neon with some bromine vapor) in a cylinder with a high potential difference (500–1200 V) between the central wire and the walls. When radiation ionizes the gas, the ions allow current to flow briefly, resulting in the characteristic click.

17.7 Measuring the Rate of Nuclear Decay

Geiger counters and scintillation counters are used to measure the rate at which a radioactive nucleus decays (Box 17.2). Each click of a Geiger counter or flash of a phosphor in a scintillation counter indicates that one nuclear disintegration has been detected. The **activity** of a sample is the number of nuclear disintegrations in a given time interval divided by the length of the interval. The SI unit of activity is the **becquerel** (Bq): 1 Bq is equal to one nuclear disintegration per second. Another commonly used (non-SI) unit of radioactivity is the curie (Ci). It is equal to 3.7×10^{10} nuclear disintegrations per second, the radioactive output of 1 g of radium-226. Because the curie is a very large unit, most activities are expressed in millicuries (mCi) or microcuries (μCi). Table 17.4 summarizes these units.

The equation for the decay of a nucleus (parent nucleus ⟶ daughter nucleus + radiation) has exactly the same form as a unimolecular elementary reaction (Section 14.7), with an unstable nucleus taking the place of a reactant molecule. This type of decay is expected for a process that does not depend on any external factors but only on the instability of the nucleus. The rate of nuclear decay depends only on the identity of the isotope, not on its chemical form or temperature.

TABLE 17.4 Radiation Units*

Property	Unit name	Symbol	Definition
activity	becquerel	Bq	1 disintegration per second
	curie	Ci	3.7×10^{10} disintegrations per second
absorbed dose	gray	Gy	$1\ \mathrm{J \cdot kg^{-1}}$
	radiation absorbed dose	rad	$10^{-2}\ \mathrm{J \cdot kg^{-1}}$
dose equivalent	sievert	Sv	$Q \times$ absorbed dose†
	roentgen equivalent man	rem	$Q \times$ absorbed dose†

*Former units are in red.
†Q is the relative biological effectiveness of the radiation. Normally, $Q < 1\ \mathrm{Sv \cdot Gy^{-1}}$ for γ, β, and most other radiation, but $Q < 20\ \mathrm{Sv \cdot Gy^{-1}}$ for α radiation and fast neutrons. A further factor of 5 (that is, $5Q$) is used for bone under certain circumstances.

As in a unimolecular chemical reaction, the rate law for nuclear decay is first order. That is, the relation between the rate of decay and the number N of radioactive nuclei present is given by the **law of radioactive decay:**

$$\text{Activity} = \text{rate of decay} = k \times N \qquad (2)^*$$

In this context, k is called the **decay constant.** The law tells us that the activity of a radioactive sample is proportional to the number of atoms in the sample. As we saw in Section 14.4, a first-order rate law implies an exponential decay. It follows that the number N of nuclei remaining after a time t is given by

$$N = N_0 e^{-kt} \qquad (3)^*$$

where N_0 is the number of radioactive nuclei present initially (at $t = 0$); this expression is plotted in Fig. 17.18.

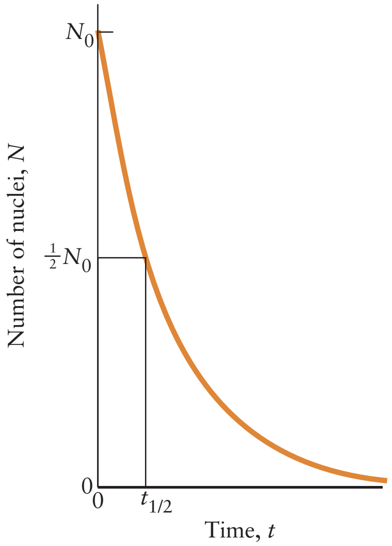


FIGURE 17.18 The exponential decay of the activity of a sample shows that the number of radioactive nuclei in the sample also decays exponentially with time. The curve is characterized by the half-life, $t_{1/2}$.

EXAMPLE 17.3 Using the law of radioactive decay

One of the reasons why thermonuclear weapons have to be serviced regularly is the nuclear decay of the tritium that they contain. Suppose a tritium sample of mass 1.00 g is stored. What mass of that isotope will remain after 5.0 a (1 a = 1 year)? The decay constant of tritium is $0.0564\ \mathrm{a^{-1}}$.

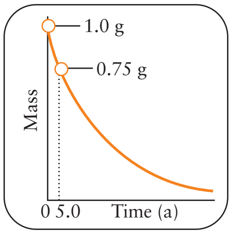
Anticipate Because the decay constant corresponds to a small fraction of the nuclei decaying per year, we should expect that most of the tritium will remain after 5 years.

PLAN The total mass of isotope in a sample is proportional to the number of nuclei of that isotope that the sample contains; therefore, the time dependence of the mass of a radioactive isotope follows the same radioactive decay law as the number of nuclides in the sample. That is, because $m \propto N$, in place of Eq. 3 we can write $m = m_0 e^{-kt}$ where m is the total mass of the radioactive isotope at time t and m_0 is its initial mass.

SOLVE

From $m = m_0 e^{-kt}$,

$$m = (1.00\ \mathrm{g}) \times e^{-(0.0564\ \mathrm{a^{-1}}) \times (5.0\ \mathrm{a})}$$
$$= 0.75\ \mathrm{g}$$



Evaluate As expected, only a small amount of the isotope has decayed; 0.75 g remains after 5.0 years.

Self-Test 17.5A The decay constant for fermium-254 is 210 s^{-1}. What mass of the isotope will be present if a sample of mass 1.00 μg is kept for 10. ms?

[***Answer:*** 0.12 μg]

Self-Test 17.5B The decay constant for the nuclide neptunium-237 is $3.3 \times 10^{-7}\ a^{-1}$. What mass of the isotope will be present if a sample of mass 5.0 μg survives for 1.0 Ma (1.0 million years)?

Radioactive decay is normally discussed in terms of the **half-life,** $t_{1/2}$, the time needed for half the initial number of nuclei to disintegrate. Just as we did in Section 14.5, we find the relation between $t_{1/2}$ and k by setting $N = \frac{1}{2}N_0$ and $t = t_{1/2}$ in Eq. 3:

$$t_{1/2} = \frac{\ln 2}{k} \qquad (4)^*$$

This equation shows that, the larger the value of k, the shorter the half-life of the nuclide. Nuclides with short half-lives are less stable than nuclides with long half-lives. They are more likely to decay in a given period of time and are "hotter" (more intensely radioactive) than nuclides with long half-lives.

Thinking point: Might there be advantages in nuclear reactors producing intensely radioactive waste?

Half-lives span a very wide range (Table 17.5). Consider strontium-90, for which the half-life is 28.1 a. This nuclide is present in nuclear **fallout,** the fine dust that settles from clouds of airborne particles after the explosion of a nuclear bomb, and may also be present in the accidental release of radioactive materials into the air. Because it is chemically very similar to calcium, strontium may accompany that element through the environment and become incorporated into bones; once there, it continues to emit radiation for many years. About 10 half-lives (for strontium-90, 281 a) must pass before the activity of a sample has fallen to 1/1000 of its initial value. Iodine-131, which was released in the accidental fire at the Chernobyl nuclear power plant, has a half-life of only 8.05 d, but it accumulates in the thyroid gland. Several cases of thyroid cancer were linked to iodine-131 exposure from the accident. Plutonium-239 has a half-life of 24 ka (24 000 years). Consequently, very long term storage facilities are required for plutonium waste, and land contaminated with plutonium cannot be inhabited again for thousands of years without expensive remediation efforts.

TABLE 17.5 Half-Lives of Radioactive Isotopes*

Nuclide	Half-life, $t_{1/2}$
tritium	12.3 a
carbon-14	5.73 ka
carbon-15	2.4 s
potassium-40	1.26 Ga
cobalt-60	5.26 a
strontium-90	28.1 a
iodine-131	8.05 d
cesium-137	30.17 a
radium-226	1.60 ka
uranium-235	0.71 Ga
uranium-238	4.5 Ga
fermium-244	3.3 ms

*d = day, a = year.

The constant half-life of a nuclide is used to determine the ages of archaeological artifacts. In **isotopic dating,** we measure the activity of the radioactive isotopes that they contain. Isotopes used for dating objects include uranium-238, potassium-40, and tritium. However, the most important example is **radiocarbon dating,** which uses the β decay of carbon-14, for which the half-life is 5730 a.

Carbon-12 is the principal isotope of carbon, but a small proportion of carbon-14 is present in all living organisms. Its nuclei are produced when nitrogen nuclei in the atmosphere are bombarded by neutrons formed in the collisions of cosmic rays with other nuclei:

$$^{14}_{7}N + ^{1}_{0}n \longrightarrow ^{14}_{6}C + ^{1}_{1}p$$

Carbon-14 atoms are produced in the atmosphere at an almost constant rate and, as a result, the proportion of carbon-14 to carbon-12 atoms in the atmosphere tends to be constant over time. Carbon-14 atoms enter living organisms as $^{14}CO_2$ through photosynthesis and digestion. They leave the organisms by the normal processes of excretion and respiration and also because the nuclei decay at a steady rate. As a result, all living organisms have a fixed ratio (of about 1 to 10^{12}) of carbon-14 atoms to carbon-12 atoms, and 1.0 g of naturally occurring carbon has an activity of 15 disintegrations per minute.

Nuclear testing has increased the amount of carbon-14 in the air, and sensitive radiocarbon dating techniques take this increase into account.

When an organism dies, it no longer exchanges carbon with its surroundings. However, carbon-14 nuclei already inside the organism continue to decay with a constant half-life, and so the ratio of carbon-14 to carbon-12 decreases. The ratio observed in a sample of dead tissue can therefore be used to estimate the time since death.

In the technique developed by Willard Libby in Chicago in the late 1940s, the proportion of carbon-14 in a sample is determined by monitoring the β radiation from

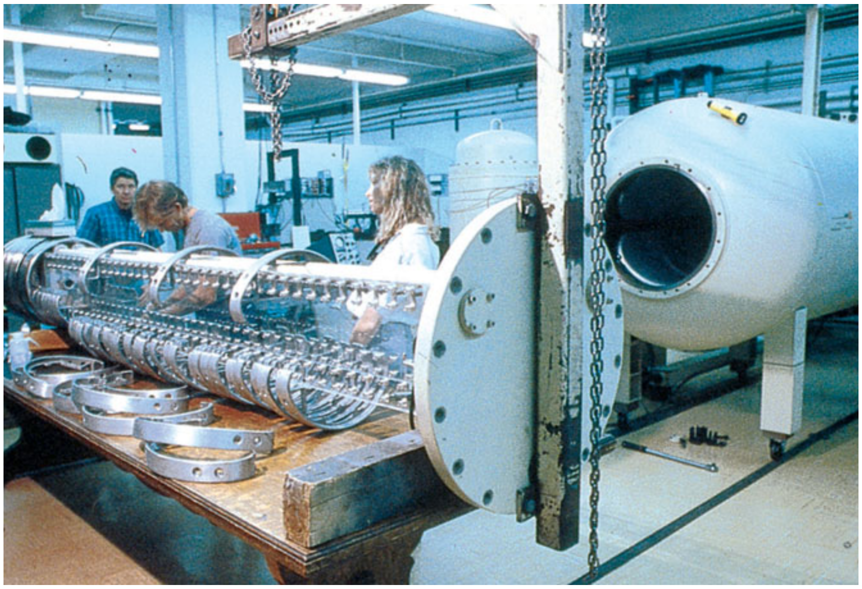


FIGURE 17.19 In a modern carbon-14 dating measurement, a mass spectrometer is used to determine the proportion of carbon-14 nuclei in the sample relative to the number of carbon-12 nuclei.

CO_2 obtained by burning the sample. This procedure is illustrated in Example 17.4. In the modern version of the technique, which requires only a few milligrams of sample, the carbon atoms are converted into C^- ions by bombardment of the sample with cesium atoms. The C^- ions are then accelerated with electric fields, and the carbon isotopes are separated and counted with a mass spectrometer (Fig. 17.19).

EXAMPLE 17.4 Interpreting carbon-14 dating

A carbon sample of mass 1.00 g from wood found in an archaeological site in Arizona underwent 7.90×10^3 carbon-14 disintegrations in a period of 20.0 h. In the same period, 1.00 g of carbon from a modern source underwent 1.84×10^4 disintegrations. Calculate the age of the sample, given that the half-life of ^{14}C is 5.73 ka.

Anticipate Because the half-life of ^{14}C is 5.73 ka and the activity of the sample has fallen to less than half that of the modern sample, we should expect that it is more than 5730 years old.

PLAN First, we rearrange Eq. 3 to give an expression for the time and then express k in terms of $t_{1/2}$ by using Eq. 4. We assume that the carbon-14 activity of the modern sample is the same as the *original* activity in the ancient sample. Therefore, N/N_0 is equal to the ratio of the number of disintegrations in the ancient and modern samples.

SOLVE

From $N = N_0e^{-kt}$,

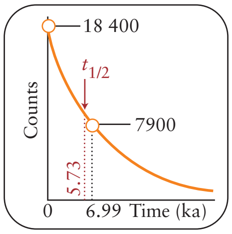
$$t = -\frac{1}{k}\ln\left(\frac{N}{N_0}\right)$$

From $t_{1/2} = (\ln 2)/k$,

$$t = -\frac{t_{1/2}}{\ln 2}\ln\left(\frac{N}{N_0}\right)$$

Substitute the data.

$$t = -\frac{5.73\text{ ka}}{\ln 2} \times \ln\left(\frac{7900}{18\,400}\right)$$
$$= 6.99\text{ ka}$$



Evaluate As expected, the sample is more than 5730 years old. We can conclude that approximately 7000 years have elapsed since the piece of wood was part of a living tree.

Self-Test 17.6A A sample of carbon of mass 250. mg from wood found in a tomb in Israel underwent 2480 carbon-14 disintegrations in 20. h. Estimate the time since death, assuming the same activity for a modern sample as in Example 17.4.

[***Answer:*** 5.1 ka]

Self-Test 17.6B A sample of carbon of mass 1.00 g from scrolls found near the Dead Sea underwent 1.4×10^4 carbon-14 disintegrations in 20. h. Estimate the approximate time since the sheepskins composing the scrolls were removed from the sheep, assuming the same activity for a modern sample as in Example 17.4.

The law of radioactive decay implies that the number of radioactive nuclei decreases exponentially with time with a characteristic half-life. Radioactive isotopes are used to determine the ages of objects.

17.8 Uses of Radioisotopes

Radioisotopes are radioactive isotopes. They are used not only to cure disease (as described in Box 17.1), but also to preserve food, to trace mechanisms of reactions, and to power equipment in spacecraft.

Radioactive **tracers** are isotopes that are used to track how substances change and move. For example, a sample of sugar can be **labeled** with carbon-14; that is, some carbon-12 atoms in sugar molecules are replaced by carbon-14 atoms, which can be detected by radiation counters. In this way, the progress through the body of even a tiny amount of sugar molecules, too small an amount to be detected by other means, can be monitored. Fertilizers labeled with radioactive nitrogen, phosphorus, or potassium are used to follow the mechanism of plant growth and the passage of these elements through the environment. Chemists and biochemists use tracers to help determine the mechanisms of reactions. For example, if water containing oxygen-18 is used in photosynthesis, the oxygen produced is oxygen-18:

$$6\,CO_2(g) + 6\,H_2{}^{18}O(l) \longrightarrow C_6H_{12}O_6(s, \text{glucose}) + 6\,{}^{18}O_2(g)$$

This result shows that the oxygen produced in photosynthesis comes from the water molecules, not the carbon dioxide molecules.

Radioisotopes have important commercial applications. For example, americium-241 is used in smoke detectors. Its role is to ionize any smoke particles, which then allow a current to flow and set off the alarm. Exposure to radiation is also used to sterilize food and inhibit the sprouting of potatoes. Radioisotopes that give off a lot of energy as heat are used to provide power in remote locations, where refueling of generators is not possible. The instruments in unmanned spacecraft, such as *Voyager 2*, are powered by radiation from isotopes with long half-lives, such as plutonium.

Isotopes are also used to study the environment. Just as carbon-14 is used to date organic materials, geologists can determine the age of very old substances such as rocks by measuring the abundance in rocks of radioisotopes with longer half-lives. Uranium-238 ($t_{1/2}$ = 4.5 Ga, 1 Ga = 10^9 years) and potassium-40 ($t_{1/2}$ = 1.26 Ga) are used to date very old rocks. For example, potassium-40 decays by electron capture to form argon-40. The rock is placed under vacuum and crushed, and a mass spectrometer is used to measure the amount of argon gas that escapes. This technique was used to determine the age of rocks collected on the surface of the Moon; they were found to be 3.5–4.0 billion years old, about the same age as the oldest rocks on Earth.

Radioisotopes are used as long-lasting power sources, to study the environment, and to track movement. They are used in biology to trace metabolic pathways, in chemistry to trace reaction mechanisms, and in geology to determine the ages of rocks.

NUCLEAR ENERGY

Nuclear reactions can release huge amounts of energy, and nuclear reactors are widely used to provide power. The benefits of nuclear power include the large quantity of energy that can be obtained from a small mass of fuel and the absence of chemical pollution of the kind associated with fossil fuels. However, like other powerful resources, nuclear energy presents us with great technical challenges and hazards. The following sections outline some of the principles.

17.9 Mass–Energy Conversion

The energy released when the nucleons in a nucleus adopt a more stable arrangement can be calculated by comparing the masses of the nuclear reactants and the nuclear products. Einstein's theory of relativity tells us that the mass of an object is a measure of its energy content: the greater the mass of an object, the greater its energy. Specifically, the total energy, E, and the mass, m, are related by Einstein's famous equation

$$E = mc^2 \qquad (5)^*$$

where c is the speed of light ($3.00 \times 10^8\ \text{m·s}^{-1}$). It follows from this relation that loss of energy is always accompanied by loss of mass.

The mass loss that always accompanies the loss of energy is normally far too small to detect. Even in a strongly exothermic chemical reaction, such as one that releases 10^3 kJ of energy, the mass of the products and the reactants differ by only 10^{-8} g. In a nuclear reaction, the energy changes are very large, the mass loss is measurable, and we can calculate the energy released from the observed change in mass.

The **nuclear binding energy,** E_{bind}, is the energy *released* when protons and neutrons come together to form a nucleus. All binding energies are positive, which means that a nucleus has a lower energy than its constituent nucleons; the greater the binding energy, the lower the energy of the nuclide. Binding energy is usually reported as the energy per nucleon, and another way to think of binding energy is as the average energy that must be supplied to separate a nucleon from a nucleus. We can use Einstein's equation to calculate the nuclear binding energy from the difference in mass, Δm, between the nucleus and the separated nucleons. For example, iron-56 has 26 protons, each of mass m_p, and 30 neutrons, each of mass m_n. The difference in mass between the nucleus and the separate nucleons is

$$\Delta m = \sum m(\text{products}) - \sum m(\text{reactants}) = m(^{56}_{26}\text{Fe}) - (26m_p + 30\ m_n)$$

We can calculate the binding energy from the difference in mass:

$$E_{\text{bind}} = |\Delta m| \times c^2 \qquad (6)^*$$

The absolute value of the mass difference is used because all binding energies are positive. We report binding energies in electronvolts (eV) or, more specifically, millions of electronvolts (1 MeV = 10^6 eV):

$$1\ \text{eV} = 1.602\ 18 \times 10^{-19}\ \text{J}$$

Because the masses of nuclides are so small, they are normally reported as a multiple of the **atomic mass constant,** m_u. The atomic mass constant is defined as exactly $^1/_{12}$ the mass of one atom of carbon-12:

$$m_u = \frac{m(^{12}\text{C})}{12}$$

Current determinations of the mass of carbon-12 give

$$m_u = 1.6605 \times 10^{-27}\ \text{kg}$$

The mass of an atom in terms of the atomic mass constant is numerically the same as the molar mass in grams per mole. For instance, the molar mass of carbon-12 is exactly 12 g·mol^{-1}, and the mass of a carbon-12 atom is exactly $12m_u$.

A note on good practice: Distinguish the atomic mass constant m_u from the atomic mass unit u. If the molar mass of the nuclide is M, the mass of the nuclide is written either $(M/\text{g mol}^{-1})m_u$ (no gap, a multiple of the constant) or $(M/\text{g mol}^{-1})$ u (a gap, a multiple of the unit). For instance, for ^{19}F, for which $M = 19.00\ \text{g mol}^{-1}$, the mass of one atom is written as either $19.00m_u$ or 19.00 u. The two are related by m_u = 1 u. The unit 1 u used to be written 1 amu and you might still encounter that form.

When calculating $|\Delta m|$ for a nuclear reaction we use the mass of an atom of ^{1}H in place of the mass of each proton. This strategy allows us to use readily available isotope masses instead of the masses of bare atomic nuclei to calculate $|\Delta m|$, because the number of

electrons in the isotope will be the same as the total number of electrons in the ^1H atoms on the other side of the equation and the masses of the electrons cancel. The contribution to the total mass that is due to the electron–nucleus binding energy is only about $m_u/10^6$ per proton, and so it can be ignored in elementary calculations.

EXAMPLE 17.5 **Calculating the nuclear binding energy**

Calculate the nuclear binding energy in electronvolts for a helium-4 nucleus, given the following masses: ^4He, $4.0026m_u$; ^1H, $1.0078m_u$; n, $1.0087m_u$.

Anticipate Because nuclear reactions can release huge amounts of energy, we should expect a large value for the nuclear binding energy.

PLAN The nuclear binding energy is the energy released in the formation of the nucleus from its nucleons. Use H atoms instead of protons to account for the masses of the electrons in the He atom produced. Write the nuclear equation for the formation of the nuclide from hydrogen atoms and neutrons, and calculate the difference in masses between the products and the reactants; convert the result from a multiple of the atomic mass constant into kilograms. Then, use the Einstein relation to calculate the energy corresponding to this loss of mass and convert the units to electronvolts.

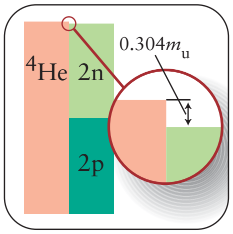
SOLVE

Write the nuclear equation.

$$2\,^1H + 2\,^1n \longrightarrow {}^4He$$

Calculate the change in mass.

$$\begin{aligned}\Delta m &= m(^4He) - (2m_p + 2m_n)\\ &= 4.0026m_u - \{2(1.0078) + 2(1.0087)\}m_u\\ &= -0.0304m_u\end{aligned}$$



Express the change in mass in kilograms.

$$\Delta m = -0.0304 \times 1.6605 \times 10^{-27}\text{ kg}$$

Calculate the binding energy from $E_{bind} = |\Delta m| \times c^2$,

$$\begin{aligned}E_{bind} &= |-0.0304 \times 1.6605 \times 10^{-27}\text{ kg}| \times (3.00 \times 10^8\text{ m·s}^{-1})^2\\ &= 4.54 \times 10^{-12}\text{ kg·m}^2\text{s}^{-2} = 4.54 \times 10^{-12}\text{J}\end{aligned}$$

Convert the binding energy to millions of electronvolts:

$$E_{bind} = 4.54 \times 10^{-12}\text{J} \times \frac{1\text{ eV}}{1.602 \times 10^{-19}\text{J}} \times \frac{1\text{ MeV}}{10^6\text{ eV}} = 28.3\text{ MeV}$$

Evaluate The value of the binding energy shows that 4.54 pJ (1 pJ = 10^{-12} J) or 28.3 MeV is released when one ^4He nucleus forms from its nucleons. (Note that in the penultimate step we used 1 kg·m^2·s^{-2} = 1 J.) Although this may seem only a small energy, on the atomic scale it is very large, as expected. The total binding energy of 1 mol He atoms is 1.09×10^{13} J, or 10.9 TJ.

Self-Test 17.7A Calculate the binding energy of a carbon-12 nucleus in electronvolts.

[***Answer:*** 92.3 MeV]

Self-Test 17.7B Calculate the binding energy of a uranium-235 nucleus in electronvolts. The mass of one uranium-235 atom is $235.0439m_u$.

Figure 17.20 shows the binding energy per nucleon, E_{bind}/A, for the elements. The graph shows that nucleons are bonded together most strongly in the elements near iron and nickel. This high binding energy is one of the reasons why iron and nickel are so

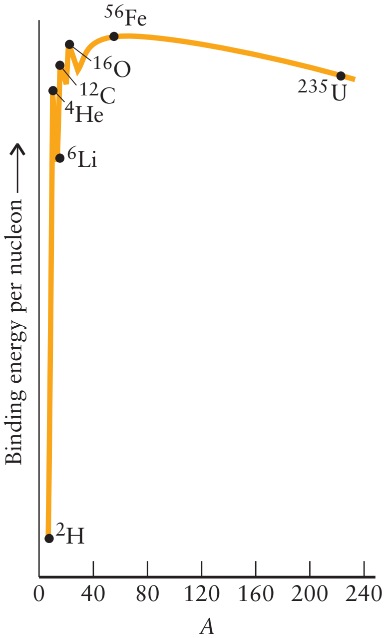


FIGURE 17.20 The variation of the nuclear binding energy per nucleon. The maximum binding energy per nucleon occurs near iron and nickel. Their nuclei have the lowest energies of all because their nucleons are the most tightly bound. (The vertical axis is E_{bind}/A.)

abundant in meteorites and on a rocky planet such as Earth. The binding energy per nucleon is less for all other nuclides. We can infer that nuclei of light atoms become more stable when they "fuse" together and that heavy nuclei become more stable when they undergo "fission" and split into lighter nuclei.

> ***Nuclear binding energies are determined by applying Einstein's formula to the mass difference between the nucleus and its components. Iron and nickel have the highest binding energy per nucleon.***

17.10 Nuclear Fission

In 1938, Lise Meitner, Otto Hahn, and Fritz Strassmann realized that, by bombarding heavy atoms such as uranium with neutrons, they could "split" the atoms into smaller fragments in fission reactions, releasing huge amounts of energy. We can estimate the energy that would be released by using Einstein's equation, as we did in Example 17.5.

EXAMPLE 17.6 Calculating the energy released during fission

When uranium-235 nuclei are bombarded with neutrons, they can split apart in a variety of ways, like glass balls that shatter into pieces of different sizes. In one process, uranium-235 forms barium-142 and krypton-92:

$$^{235}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{142}_{56}\text{Ba} + {}^{92}_{36}\text{Kr} + 2\,{}^{1}_{0}\text{n}$$

Notice that we do not cancel neutrons, although they appear on both sides of the equation. Like equations for elementary chemical reactions, nuclear equations show the specific process.

Calculate the energy (in joules) released when 1.0 g of uranium-235 undergoes this fission reaction. The masses of the particles are $^{235}_{92}\text{U}$, 235.04m_u; $^{142}_{56}\text{Ba}$, 141.92m_u; $^{92}_{36}\text{Kr}$, 91.92m_u; n, 1.0087m_u.

Anticipate Fission processes are used to produce energy; therefore, we should expect that a large amount of energy will be released.

PLAN If we know the mass loss, we can find the energy released by using Einstein's equation. Therefore, we must calculate the total mass of the particles on each side of the nuclear equation, take the difference, and substitute the mass difference into Eq. 6. Then we determine the number of nuclei in the sample from $N = m(\text{sample})/m(\text{atom})$ and, finally, multiply the energy released from the fission of one nucleus by that number to find the energy released by the sample.

SOLVE

Calculate mass of products.

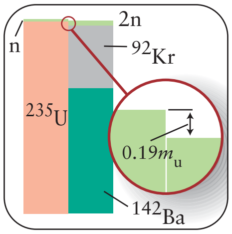
$$m(\text{products}) = m(\text{Ba}) + m(\text{Kr}) + 2m(\text{n})$$
$$= \{141.92 + 91.92 + 2(1.0087)\}m_u$$
$$= 235.86m_u$$

Calculate mass of reactants.

$$m(\text{reactants}) = m(\text{U}) + m(\text{n})$$
$$= 235.04m_u + 1.0087m_u = 236.05m_u$$

Calculate the change in mass.

$$\Delta m = 235.86m_u - 236.05m_u = -0.19m_u$$



Express this change in kilograms.

$$\Delta m = -0.19 \times 1.6605 \times 10^{-27}\ \text{kg}$$

Calculate the change in energy for the fission of one nucleus from $\Delta E = \Delta mc^2$.

$$\Delta E = (-0.19 \times 1.6605 \times 10^{-27}\ \text{kg}) \times (3.00 \times 10^8\ \text{m}\cdot\text{s}^{-1})^2$$
$$= (-0.19 \times 1.6605 \times 10^{-27}) \times (3.00 \times 10^8)^2\ \text{J}\ (= -2.8 \times 10^{-11}\ \text{J})$$

Find the number of atoms, N, in the sample from $N = m(\text{sample})/m(\text{atom})$.

$$N = \frac{1.0 \times 10^{-3}\ \text{kg}}{235.04 m_u} = \frac{1.0 \times 10^{-3}}{235.04 \times 1.6605 \times 10^{-27}}\ (= 2.6 \times 10^{21})$$

Calculate the total energy change of the sample from $\Delta E(\text{total}) = N\Delta mc^2$.

$$\Delta E = \frac{1.0 \times 10^{-3}}{235.04 \times 1.6605 \times 10^{-27}} \times \{-0.19 \times 1.6605 \times 10^{-27} \times (3.00 \times 10^8)^2\}\ \text{J}$$
$$= -7.3 \times 10^{10}\ \text{J}$$

Evaluate The energy released is large, as expected; 73 GJ is 1.3 million times as much energy as would be produced by burning 1.0 g of methane, the main component of natural gas.

Self-Test 17.8A Another mode in which uranium-235 can undergo fission is

$$^{235}_{52}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{135}_{52}\text{Te} + {}^{100}_{40}\text{Zr} + {}^{1}_{0}\text{n}$$

Calculate the energy released when 1.0 g of uranium-235 undergoes fission in this way. The masses needed are $^{235}_{92}$U, 235.04m_u; n, 1.0087m_u; $^{135}_{52}$Te, 134.92m_u; $^{100}_{40}$Zr, 99.92m_u.

[***Answer:*** 77 GJ]

Self-Test 17.8B A nuclear reaction that can cause great destruction is one of many that take place in the ^{235}U atomic bomb:

$$^{235}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{138}_{56}\text{Ba} + {}^{86}_{36}\text{Kr} + 12\,{}^{1}_{0}\text{n}$$

How much energy is released when 1.0 g of uranium-235 undergoes fission in this manner? The additional masses needed are $^{138}_{56}$Ba, 137.91m_u; $^{86}_{36}$Kr, 85.91m_u.

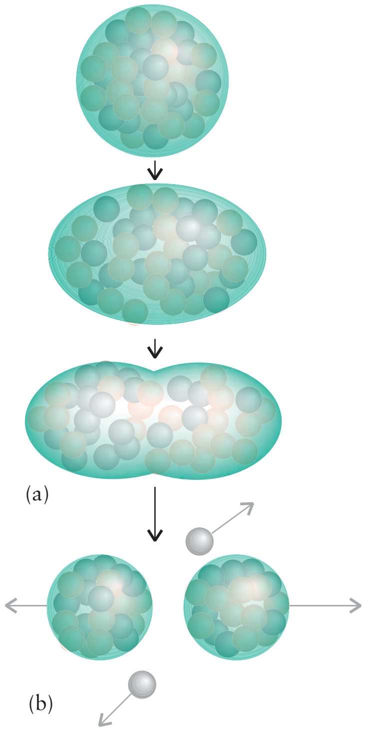


FIGURE 17.21 In spontaneous nuclear fission, the oscillations of the heavy nucleus (a) in effect tear the nucleus apart, thereby forming two or more smaller nuclei of similar mass (b). Here, two neutrons are released.

Spontaneous nuclear fission takes place when the natural oscillations of a heavy nucleus cause it to break into two nuclei of similar mass (Fig. 17.21). We can think of the nucleus as distorting into a dumbbell shape and then breaking into two smaller nuclei. An example is the spontaneous disintegration of americium-244 into iodine and molybdenum:

$$^{244}_{95}\text{Am} \longrightarrow {}^{134}_{53}\text{I} + {}^{107}_{42}\text{Mo} + 3\,{}^{1}_{0}\text{n}$$

Fission does not occur in precisely the same way in every instance. For example, more than 200 isotopes of 35 different elements have been identified among the fission products of uranium-235, with most products having mass numbers close to 90 or 130 (Fig. 17.22).

Induced nuclear fission is fission caused by bombarding a heavy nucleus with neutrons (Fig. 17.23). The nucleus breaks into two fragments when struck by a projectile. Nuclei that can undergo induced fission are called **fissionable.** For most nuclei, fission takes place only if the impinging neutrons travel so rapidly that they can smash into the nucleus and drive it apart with the shock of impact; uranium-238 undergoes fission in this way. **Fissile nuclei,** however, are nuclei that can be nudged into breaking apart even by slow neutrons. They include uranium-235, uranium-233, and plutonium-239—the fuels of nuclear power plants.

Once nuclear fission has been induced, it can continue, even if the supply of neutrons from outside is discontinued, provided that the fission produces more neutrons. Such self-sustaining fission takes place in uranium-235, which undergoes numerous fission processes, including

$$^{235}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{141}_{56}\text{Ba} + {}^{92}_{36}\text{Kr} + 3\,{}^{1}_{0}\text{n}$$

If the three product neutrons strike three other fissile nuclei, then after the next round of fission there will be nine neutrons, which can induce fission in nine more nuclei. In the language of Section 14.9, neutrons are **carriers** in a branched chain reaction (Fig. 17.24).

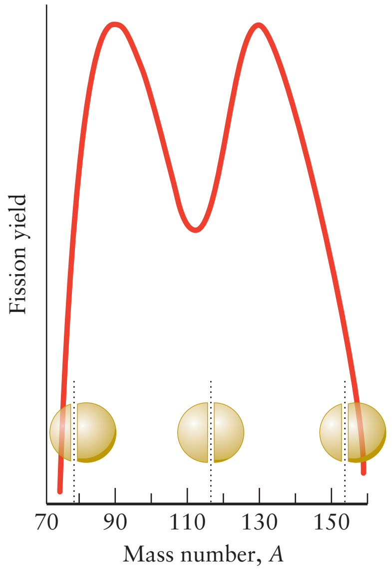

FIGURE 17.22 The fission yield of uranium-235. Note that the majority of fission products lie in the regions close to A = 90 and 130 and that relatively few nuclides corresponding to symmetrical fission (A close to 117) are formed.

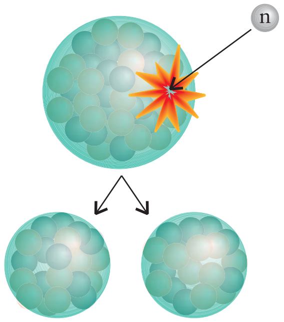

FIGURE 17.23 In induced nuclear fission, the impact of an incoming neutron causes the nucleus to break apart.

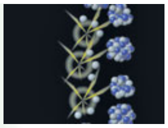
Neutrons produced in a chain reaction are moving very fast, and most escape into the surroundings without colliding with another fissionable nucleus. However, if a large enough number of uranium nuclei are present in the sample, enough neutrons can be captured to sustain the chain reaction. In that case, there is a **critical mass,** a mass of fissionable material above which so few neutrons escape from the sample that the fission chain reaction is sustained. If a sample is **supercritical,** with a mass in excess of the critical value, then the reaction is not only self-sustaining but difficult to control and may result in an explosion. The critical mass for a solid sphere of pure plutonium of normal density is about 15 kg, about the size of a grapefruit. The critical mass is smaller if the metal is compressed by detonating a conventional explosive that surrounds it. Then the nuclei are pressed closer together and become more effective at blocking the escape of neutrons. The critical mass can be as low as 5 kg for highly compressed plutonium. A sample that has less than the critical mass for its density is said to be **subcritical.**

In a nuclear weapon, the fissile material is initially subcritical. The challenge is to produce a supercritical mass so rapidly that the chain reaction takes place uniformly throughout the metal. Supercriticality can be achieved by shooting two subcritical blocks toward each other (as was done in the bomb that fell on Hiroshima) or by implosion of a single subcritical mass (the technique used in the bomb that destroyed Nagasaki). A strong neutron emitter, typically polonium, helps to initiate the chain reaction.

Explosive fission cannot occur in a nuclear reactor, because the fuel is not dense enough. Instead, reactors sustain a much slower, controlled chain reaction by making efficient use of a limited supply of neutrons and slowing the neutrons down. The fuel is shaped into long rods and inserted into a **moderator,** a material that slows down the neutrons as they pass between fuel rods; the slower neutrons have a greater probability of collision with a nucleus (Fig. 17.25). Slow neutrons have three significant roles: they do not induce the fission of fissionable (as distinct from fissile) material; they are most effectively absorbed by the fissile uranium-235; and they are more easily controlled. The first moderator used was graphite. Heavy water, D_2O, is also an effective neutron moderator, but light-water reactors (LWRs) use ordinary water as a moderator. They are the most common type of nuclear reactor in the United States (Fig. 17.26).



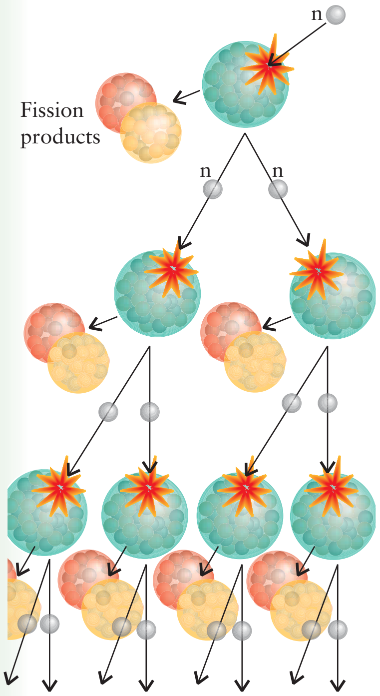


FIGURE 17.24 A self-sustaining chain reaction, in which neutrons are the chain carriers, takes place when induced fission produces more than one neutron per fission event. These newly produced neutrons can stimulate fission in increasingly greater numbers of other nuclei.

Animation 17.24

If the rate of the chain reaction exceeds a certain level, the reactor will become too hot and begin to melt. Control rods—rods made from neutron-absorbing elements, such as boron or cadmium, and inserted between the fuel rods—help to control the number of available neutrons and the rate of nuclear reaction.

One of the many problems of nuclear power is the availability of fuel: uranium-235 reserves are only about 0.7% those of the nonfissile uranium-238, and the separation of the isotopes is costly (Section 17.12). One solution is to synthesize fissile nuclides from other elements. In a **breeder reactor,** a reactor that is used to create nuclear fuel, the neutrons are not moderated. Their high speeds result in the formation of not only uranium-235 but also some fissile plutonium-239, which can be used as fuel (or for warheads). However, breeder reactors are more hazardous to operate than nuclear power plants. They run very hot, and the fast reactions require more careful control than reactors used for nuclear power generation.

Nuclear energy can be extracted by arranging for a nuclear chain reaction to take place in a critical mass of fissionable material, with neutrons as the chain carriers. A moderator is used to reduce the speeds of the neutrons in a reactor that uses fissile material.

17.11 Nuclear Fusion

Although fission reactors do not generate chemical pollution, they do produce highly hazardous radioactive waste. However, another kind of nuclear reaction being investigated for power generation is essentially free of long-lived radioactive waste products, and its abundant fuel is readily extracted from seawater. The reaction is the fusion of hydrogen nuclei to form helium nuclei.

From the plot in Fig. 17.20, we can see that there is a large increase in nuclear binding energy on going from light elements such as deuterium to heavier elements. Consequently, energy is released when deuterium nuclei fuse together to form nuclei of

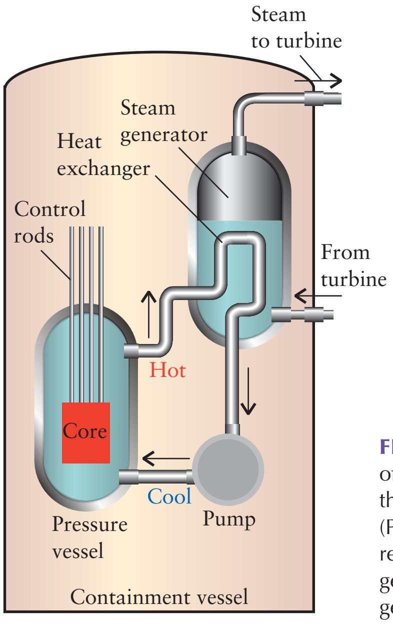

FIGURE 17.25 A schematic representation of one type of nuclear reactor in which water acts as a moderator for the nuclear reaction. In this pressurized water reactor (PWR), the coolant is water under pressure. The fission reactions produce heat, which boils water in the steam generator; the resulting steam turns the turbines that generate electricity.

FIGURE 17.26 The reactor core of a typical light-water reactor (LWR) nuclear power plant is immersed in water.

those elements. Unfortunately, the strong electrical repulsion between protons makes it difficult for them to approach each other closely enough to fuse together. The nuclei of the heavier isotopes of hydrogen fuse together more readily, because the additional neutrons contribute to the strong force and help to capture the approaching protons. To achieve the high kinetic energies needed for successful collisions, fusion reactors need to operate at temperatures above 10^8 K.

One fusion scheme uses deuterium (D, ^{2}H) and tritium (T, ^{3}H) in the following sequence of nuclear reactions:

$$D + D \longrightarrow {}^3He + n$$
$$D + D \longrightarrow T + p$$
$$D + T \longrightarrow {}^4He + n$$
$$D + {}^3He \longrightarrow {}^4He + p$$

Overall reaction: $6\ D \longrightarrow 2\ {}^4He + 2\ p + 2\ n$

The overall reaction releases 3×10^8 kJ for each gram of deuterium consumed. That energy corresponds to the energy generated when the Hoover Dam operates at full capacity for about an hour. Additional tritium is supplied to facilitate the process. Because tritium has a very low natural abundance and is radioactive, it is generated by bombarding lithium-6 with neutrons in the immediate surroundings of the reaction zone:

$${}^6Li + n \longrightarrow T + {}^4He$$

Nuclear fusion is very difficult to achieve because the charged nuclei must be hurled at each other with enormous kinetic energies. One way of accelerating nuclei to sufficiently high speeds is to heat them with a fission explosion: this method is used to produce a **thermonuclear explosion,** an explosion due to nuclear fusion. In "hydrogen bombs," a fission bomb (using uranium or plutonium) ignites a lithium-6 fusion bomb. Fusion bombs can be of varying destructive capacities, because there is no critical mass to maintain. Typical fusion bombs have a destructive capacity greater than 200 times that of the fission bombs that were dropped on Hiroshima and Nagasaki in World War II.

A more constructive approach to nuclear fusion—one that achieves a controlled release of nuclear energy—is to heat a **plasma,** or ionized gas, by passing an electric current through it. The very fast ions in the plasma are kept away from the walls of the container with magnetic fields. This method of achieving fusion is the subject of intense research and is beginning to show signs of success (Fig. 17.27).

Nuclear fusion makes use of the energy released when light nuclei fuse together to form heavier nuclei.

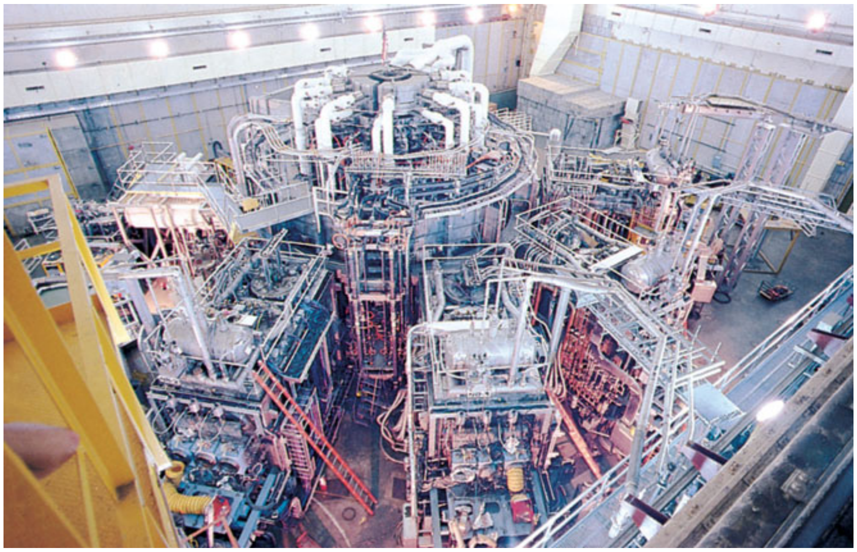

FIGURE 17.27 Research into controlled nuclear fusion is being carried out in several countries. Here we see the Tokomak fusion test reactor at the Princeton Plasma Physics Laboratory.

17.12 The Chemistry of Nuclear Power

FIGURE 17.28 Pitchblende is a common uranium ore. It is a variety of uranite, UO_2.

Chemistry is the key to the safe use of nuclear power. It is used in the preparation of the fuel itself, the recovery of important fission products, and the safe disposal or utilization of nuclear waste.

Uranium is the fuel of nuclear reactors. The most important of its minerals is *pitchblende*, UO_2 (Fig. 17.28), much of which is obtained from strip mines in New Mexico and Wyoming. Uranium is refined to reduce the ore to the metal and to enrich it; that is, to increase the abundance of a specific isotope—in this case, uranium-235. The natural abundance of uranium-235 is about 0.7%; for use in a nuclear reactor, this fraction must be increased to about 3%.

The enrichment procedure uses the small mass difference between the hexafluorides of uranium-235 and uranium-238 to separate them. The first procedure to be developed converts the uranium into uranium hexafluoride, UF_6, which can be vaporized readily. The different effusion rates of the two isotopic fluorides are then used to separate them. From Graham's law of effusion (rate of effusion $\propto 1/(\text{molar mass})^{1/2}$; Section 4.9), the rates of effusion of $^{235}UF_6$ (molar mass, 349.0 $g\cdot mol^{-1}$) and $^{238}UF_6$ (molar mass, 352.1 $g\cdot mol^{-1}$) should be in the ratio

$$\frac{\text{Rate of effusion of } ^{235}UF_6}{\text{Rate of effusion of } ^{238}UF_6} = \sqrt{\frac{352.1}{349.0}} = 1.004$$

Because the ratio is so close to 1, the vapor must be allowed to effuse repeatedly through porous barriers consisting of screens with large numbers of minute holes. In practice, it is allowed to do so thousands of times.

Because the effusion process is technically demanding and uses a lot of energy, scientists and engineers continue to look for alternative enrichment procedures. One of these approaches uses a centrifuge that rotates samples of uranium hexafluoride vapor at very high speed. This rotation causes the heavier $^{238}UF_6$ molecules to be thrown outward and collected as a solid on the outer parts of the rotor, leaving a high proportion of $^{235}UF_6$ closer to the axis of the rotor, from where it can be removed.

Spent nuclear fuel remains radioactive and consists of a mixture of uranium and fission products. Nuclear reactor waste can be processed and some of it reused, but the percentage processed depends on the price of uranium. When the price is high, as it is in the early twenty-first century, much of the nuclear waste is processed for reuse.

The processing of nuclear waste is complex. Any remaining uranium-235 must be recovered, any plutonium produced must be extracted, and the largely useless but radioactive fission products must be stored safely (Fig. 17.29). The highly radioactive fission (HRF) products from used nuclear fuel rods must be stored until their level of

FIGURE 17.29 Containers of high-level waste products, including cesium-137 and strontium-90, glow under a protective layer of water. If the canisters were unshielded, the radiation that they emit would be great enough to cause death within about 4 s.

FIGURE 17.30 This 35-year-old drum of radioactive waste has corroded and leaked radioactive materials into the soil. The drum was located in one of the nuclear waste disposal sites at the U.S. Department of Energy's Hanford, Washington, nuclear manufacturing and research facility. Several storage sites at this facility became seriously contaminated and had to be cleaned and reconfigured for more stable storage.

radioactivity is no longer dangerous (about 10 half-lives). Generally they are buried underground, but even burial of radioactive wastes is not without problems. Metal storage drums can corrode and allow liquid radioactive waste to seep into aquifers that supply drinking water (Fig. 17.30). Leakage can be minimized by incorporating the HRF products into a glass—a solid, complex network of silicon and oxygen atoms. Most of the fission products are oxides of the type that form one of the components of glass—they are network formers (see Section 6.10); that is, they promote the formation of a relatively disorderly Si–O network rather than inducing crystallization into an orderly array of atoms. Crystallization is dangerous because crystalline regions easily fracture, exposing the incorporated radioactive materials to moisture. Water could dissolve them and carry them away from the storage area. An alternative is to incorporate radioactive waste into hard ceramic materials (Section 6.11). An example is Synroc, a fracture-resistant titanate-based ceramic that can accept radioactive waste products into its lattice.

Uranium is extracted by a series of reactions that lead to uranium hexafluoride; the isotopes are then separated by a variety of procedures. Some radioactive waste is currently converted into glass or ceramic materials for storage underground.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Write, complete, and balance nuclear equations (Examples 17.1 and 17.2).

❑ 2 Use the band of stability to predict the types of decay that a given radioactive nucleus is likely to undergo (Self-Test 17.3).

❑ 3 Distinguish α, β, and γ radiation by their response to an electric field, penetrating power, and relative biological effectiveness (Sections 17.1 and 17.6).

❑ 4 Predict the amount of a radioactive sample that will remain after a given time period, given the decay constant or half-life of the sample (Example 17.3).

❑ 5 Use the half-life of an isotope to determine the age of an object (Example 17.4).

❑ 6 Calculate the nuclear binding energy of a given nuclide (Example 17.5).

❑ 7 Calculate the energy released during a nuclear reaction (Example 17.6).

❑ 8 Distinguish nuclear fission from nuclear fusion and predict which nuclides undergo each type of process (Sections 17.10 and 17.11).

❑ 9 Describe some ways of storing radioactive waste (Section 17.12).

EXERCISES

Note that the SI symbol for 1 year is 1 a and that it takes the usual prefixes, as in 1 ka = 10^3 a and 1 Ga = 10^9 a.

Exercises labeled **C** *require calculus*

Radioactive Decay

17.1 When the nucleons rearrange in the following daughter nuclei, the energy changes by the amount shown and a γ-ray is emitted. Determine the frequency and wavelength of the γ-ray in each case: (a) cobalt-60, 1.33 MeV; (b) arsenic-80, 1.64 MeV; (c) iron-59, 1.10 MeV. ($1\ \text{MeV} = 1.602 \times 10^{-13}$ J.)

17.2 Determine the frequency and wavelength of the γ-ray emitted in the decay of each of following nuclides: (a) iron-53, 3.04 MeV; (b) vanadium-52, 1.43 MeV; (c) scandium-44, 0.27 MeV. ($1\ \text{MeV} = 1.602 \times 10^{-13}$ J.)

17.3 *Isotones* are nuclides that have the same number of neutrons. Which isotopes of argon and calcium are isotones of potassium-40?

17.4 Which isotopes of krypton and selenium are isotones (see Exercise 17.3) of bromine-80?

17.5 Write the balanced nuclear equation for each of the following decays: (a) β^- decay of tritium; (b) β^+ decay of yttrium-83; (c) β^- decay of krypton-87; (d) α decay of protactinium-225.

17.6 Write the balanced nuclear equation for each of the following decays: (a) α decay of californium-250; (b) positron decay of rubidium-76; (c) electron capture by arsenic-73; (d) β^- decay of chromium-56.

17.7 Write the balanced nuclear equation for each of the following decays: (a) β^+ decay of boron-8; (b) β^- decay of nickel-63; (c) α decay of gold-185; (d) electron capture by beryllium-7.

17.8 Write the balanced nuclear equation for each of the following decays: (a) β^- decay of uranium-233; (b) proton emission of cobalt-56; (c) β^+ decay of holmium-158; (d) α decay of polonium-212.

17.9 Determine the particle emitted and write the balanced nuclear equation for each of the following nuclear transformations: (a) sodium-24 to magnesium-24; (b) ^{128}Sn to ^{128}Sb; (c) lanthanum-140 to barium-140; (d) ^{228}Th to ^{224}Ra.

17.10 Determine the particle emitted and write the balanced nuclear equation for each of the following nuclear transformations: (a) gadolinium-148 to samarium-144; (b) fluorine-17 to oxygen-17; (c) silver-112 to cadmium-112; (d) plutonium-238 to uranium-234.

17.11 Complete the following equations for nuclear reactions:
(a) ${}^{11}\text{B} + ? \longrightarrow 2\ \text{n} + {}^{13}\text{N}$
(b) $? + \text{D} \longrightarrow \text{n} + {}^{36}\text{Ar}$
(c) ${}^{96}\text{Mo} + \text{D} \longrightarrow ? + {}^{97}\text{Tc}$
(d) ${}^{45}\text{Sc} + \text{n} \longrightarrow \alpha + ?$

17.12 Complete the following equations for nuclear decay reactions:
(a) ${}^{12}\text{O} \longrightarrow 2\ \text{p} + ?$
(b) ${}^{17}\text{C} \longrightarrow ? + \text{n} + \beta^-$
(c) ${}^{148}\text{Ba} \longrightarrow {}^{147}\text{La} + ? + \text{n}$
(d) ${}^{18}\text{Ne} \longrightarrow \beta^+ + ?$

The Pattern of Nuclear Stability

17.13 The following nuclides lie outside the band of stability. Predict whether each is most likely to undergo β^- decay, β^+ decay, or α decay, and identify the daughter nucleus: (a) copper-68; (b) cadmium-103; (c) berkelium-243; (d) dubnium-260.

17.14 The following nuclides lie outside the band of stability. Predict whether each is most likely to undergo β^- decay, β^+ decay, or α decay, and identify the daughter nucleus: (a) copper-60; (b) xenon-140; (c) americium-246; (d) neptunium-240.

17.15 Identify the daughter nuclides in each step of the radioactive decay of uranium-235, if the string of particle emissions is α, β, α, β, α, α, α, β, α, β, α. Write a balanced nuclear equation for each step.

17.16 Neptunium-237 undergoes an α, β, α, α, β, α, α, α, α, β, α, β sequence of radioactive decays. Write a balanced nuclear equation for each step.

Nucleosynthesis

17.17 Complete the following nuclear equations:
(a) ${}^{14}_{7}\text{N} + ? \longrightarrow {}^{17}_{8}\text{O} + {}^{1}_{1}\text{p}$
(b) $? + {}^{1}_{0}\text{n} \longrightarrow {}^{249}_{97}\text{Bk} + {}^{0}_{-1}\text{e}$
(c) ${}^{243}_{95}\text{Am} + {}^{1}_{0}\text{n} \longrightarrow {}^{244}_{96}\text{Cm} + ? + \gamma$
(d) ${}^{13}_{6}\text{C} + {}^{1}_{0}\text{n} \longrightarrow ? + \gamma$

17.18 Complete the following nuclear equations:
(a) $? + {}^{1}_{1}\text{p} \longrightarrow {}^{21}_{11}\text{Na} + \gamma$
(b) ${}^{1}_{1}\text{H} + {}^{1}_{1}\text{p} \longrightarrow {}^{2}_{1}\text{H} + ?$
(c) ${}^{15}_{7}\text{N} + {}^{1}_{1}\text{p} \longrightarrow {}^{12}_{6}\text{C} + ?$
(d) ${}^{20}_{10}\text{Ne} + ? \longrightarrow {}^{24}_{12}\text{Mg} + \gamma$

17.19 Complete the following equations for nuclear transmutation:
(a) ${}^{20}_{10}\text{Ne} + {}^{4}_{2}\alpha \longrightarrow ? + {}^{16}_{8}\text{O}$
(b) ${}^{20}_{10}\text{Ne} + {}^{20}_{10}\text{Ne} \longrightarrow {}^{16}_{8}\text{O} + ?$
(c) ${}^{44}_{20}\text{Ca} + ? \longrightarrow \gamma + {}^{48}_{22}\text{Ti}$
(d) ${}^{27}_{13}\text{Al} + {}^{2}_{1}\text{H} \longrightarrow ? + {}^{28}_{13}\text{Al}$

17.20 Complete the following equations for nuclear transmutation:
(a) $? + \gamma \longrightarrow {}^{0}_{-1}\text{e} + {}^{20}_{10}\text{Ne}$
(b) ${}^{44}_{22}\text{Ti} + {}^{0}_{-1}\text{e} \longrightarrow {}^{0}_{+1}\text{e} + ?$
(c) ${}^{241}_{95}\text{Am} + ? \longrightarrow 4\,{}^{1}_{0}\text{n} + {}^{248}_{100}\text{Fm}$
(d) $? + {}^{1}_{0}\text{n} \rightarrow {}^{0}_{-1}\text{e} + {}^{244}_{96}\text{Cm}$

17.21 One explanation for the existence of elements heavier than iron is the rapid neutron-capture process (r-process). In the r-process proposed to occur in supernovae, many high-speed neutrons smash into an iron nucleus. Some of these neutrons are rapidly captured, resulting in a highly unstable nucleus that immediately decays. In each decay step a neutron is converted into a proton. Write the overall nuclear equation for the absorption of six neutrons by an iron-56 nucleus and their decay to six protons.

17.22 It has been claimed that the neon present in meteorites was generated by nuclear reactions. One such reaction occurs when a silicon-28 atom is bombarded by cosmic ray protons. When one of these energetic protons is absorbed, the result is an isotope of neon, three protons, a neutron, and an α particle. Identify the isotope of neon formed and write the nuclear equation for the process.

17.23 Write a nuclear equation for each of the following processes: (a) oxygen-17 produced by α-particle bombardment of nitrogen-14; (b) americium-240 produced by neutron bombardment of plutonium-239.

17.24 Write a nuclear equation for each of the following transformations: (a) ^{257}Rf produced by the bombardment of californium-245 with carbon-12 nuclei; (b) the first synthesis of ^{266}Mt by the bombardment of bismuth-209 with iron-58 nuclei. Given that the first decay of meitnerium is by α emission, what is the daughter nucleus?

17.25 What will be the systematic name and atomic symbol given to (a) element 126; (b) element 136; (c) element 200?

17.26 What will be the systematic name and atomic symbol given to (a) element 118; (b) element 127; (c) element 202?

Nuclear Radiation

17.27 The activity of a certain radioactive source is 5.3×10^5 Bq. Express this activity in curies.

17.28 The activity of a sample containing carbon-14 is 54.8 Bq. Express this activity in microcuries.

17.29 Determine the number of disintegrations per second for radioactive sources of each of the following activities: (a) 2.5 μCi; (b) 142 Ci; (c) 7.2 mCi.

17.30 A certain Geiger counter is known to respond to only 1 of every 1000 radiation events from a sample. Calculate the activity of each radioactive source in curies, given the following data: (a) 591 clicks in 100. s; (b) 2.7×10^4 clicks in 1.5 h; (c) 159 clicks in 1.0 min.

17.31 A 2.0-kg sample absorbs an energy of 1.5 J as a result of its exposure to β radiation. Calculate the dose in rads and the dose equivalent in rems and in sieverts.

17.32 A 1.5-g sample of muscle tissue absorbs 2.6 J of energy as a result of its exposure to α radiation. Calculate the dose in rads and the dose equivalent in rems and in sieverts.

17.33 Someone is exposed to a source of β radiation that results in a dose rate of $1.0\ \text{rad}\cdot\text{d}^{-1}$. Given that nausea begins after a dose equivalent of about 100 rem, after what period will that symptom of radiation sickness be apparent?

17.34 Someone is exposed to a source of α radiation that results in a dose rate of $2.0\ \text{mrad}\cdot\text{d}^{-1}$. If nausea begins after a dose equivalent of about 100 rem, after what period will nausea become apparent?

The Rate of Nuclear Decay

17.35 Determine the decay constant for (a) tritium, $t_{1/2} = 12.3$ a; (b) lithium-8, $t_{1/2} = 0.84$ s; (c) nitrogen-13, $t_{1/2} = 10.0$ min.

17.36 Determine the half-life of (a) potassium-40, $k = 5.3 \times 10^{-10}\ \text{a}^{-1}$; (b) cobalt-60, $k = 0.132\ \text{a}^{-1}$; (c) nobelium-255, $k = 3.85 \times 10^{-3}\ \text{s}^{-1}$.

17.37 The activity of a sample of a radioisotope was found to be 2150 disintegrations per minute. After 6.0 h the activity was found to be 1324 disintegrations per minute. What is the half-life of the radioisotope?

17.38 (a) A sample of pure cobalt-60 has an activity of 1 μCi. (a) How many atoms of cobalt-60 are present in the sample? (b) What is the mass in grams of the sample?

17.39 (a) What percentage of a carbon-14 sample remains after 3.00 ka? (b) Determine the percentage of a tritium sample that remains after 12.0 a.

17.40 (a) What percentage of a strontium-90 sample remains after 8.5 a? (b) Determine the percentage of an iodine-131 sample that remains after 6.0 d.

17.41 Potassium-40, which is presumed to have existed at the formation of the Earth, is used for dating minerals. If three-fifths of the original potassium-40 exists in a rock, how old is the rock?

17.42 A piece of wood, found in an archaeological dig, has a carbon-14 activity that is 62% of the current carbon-14 activity. How old is the piece of wood?

17.43 A 250.-mg sample of carbon from a piece of cloth excavated from an ancient tomb in Nubia undergoes 1.50×10^3 disintegrations in 10.0 h. If a current 1.00-g sample of carbon shows 921 disintegrations per hour, how old is the piece of cloth?

17.44 A current 1.00-g sample of carbon shows 921 disintegrations per hour. If 1.00 g of charcoal from an archaeological dig in a limestone cave in Slovenia shows 5.50×10^3 disintegrations in 24.0 h, what is the age of the charcoal sample?

17.45 Use the law of radioactive decay to determine the activity of (a) a 1.0-mg sample of radium-226 ($t_{1/2} = 1.60$ ka); (b) a 2.0-mg sample of strontium-90 ($t_{1/2} = 28.1$ a); (c) a 0.43-mg sample of promethium-147 ($t_{1/2} = 2.6$ a). The mass of each nuclide as a multiple of the atomic mass constant (m_u) is equal to its mass number, within two significant figures.

17.46 Use the law of radioactive decay to determine the activity of (a) a 1.0-g sample of $^{235}UO_2$ ($t_{1/2} = 7.1 \times 10^8$ a); (b) a 1.0-g sample of cobalt that is 1.0% ^{60}Co ($t_{1/2} = 5.26$ a); (c) a 5.0-mg sample of thallium-200 ($t_{1/2} = 26.1$ h). The mass of each nuclide as a multiple of the atomic mass constant (m_u) is equal to its mass number, within two significant figures.

17.47 Deoxyglucose labeled with fluorine-18 is commonly used in PET scans to locate tumors. Fluorine-18 has a half-life of 109 min. How long will it take for the level of fluorine-18 in the body to drop to 10% of its initial value?

17.48 Technetium-99m (the m signifies a "metastable," or moderately stable, species) is generated in nuclear reactors and shipped to hospitals for use in medical imaging. The radioisotope has a half-life of 6.01 h. If a 165-mg sample of technetium-99m is shipped from a nuclear reactor to a hospital 125 kilometers away in a truck that averages $50.0\ \text{km}\cdot\text{h}^{-1}$, what mass of technetium-99m will remain when it arrives at the hospital?

17.49 A 1.40-g sample containing radioactive cobalt was kept for 2.50 a, at which time it was found to contain 0.266 g of ^{67}Co. The half-life of ^{67}Co is 5.27 a. What percentage (by mass) of the original sample was ^{67}Co?

17.50 A radioactive sample contains 3.25×10^{18} atoms of a nuclide that decays at a rate of 3.4×10^{13} disintegrations per 15 min. (a) What percentage of the nuclide will have decayed after 150 d? (b) How many atoms of the nuclide will remain in the sample? (c) What is the half-life of the nuclide?

C **17.51** A radioactive isotope X with a half-life of 27.4 d decays into another radioactive isotope Y with a half-life of 18.7 d, which decays into the stable isotope *Z*. Set up and solve the rate laws for the amounts of the three nuclides as a function of time, and plot your results as a graph.

C **17.52** Suppose that the nuclide Y in Exercise 17.51 is needed for medical research and that 2.00 g of nuclide X was supplied at $t = 0$. At what time will Y be most abundant in the sample?

Uses of Radioisotopes

17.53 A chemist is studying the mechanism of the following hydrolysis reaction of the organic ester methyl acetate: $CH_3COOCH_3 + H_2O \longrightarrow CH_3COOH + CH_3OH$. The question arises whether the O atom in the product methanol comes from the methyl acetate or from the water. Propose an experiment using isotopes that would allow the chemist to determine the origin of the oxygen atom.

17.54 The blood volume in a cancer patient was measured by injecting 5.0 mL of Na_2SO_4(aq) labeled with ^{35}S ($t_{1/2}$ = 87.4 d). The activity of the sample was 300 μCi. After 30. min, 10.0 mL of blood was withdrawn from the man and the activity of that sample was found to be 0.025 μCi. Report the blood volume of the patient.

17.55 What would you expect to happen to the vibrational frequency of the C—H bond of methane if the hydrogen atoms, which are normally present as ^1H, are replaced by ^2H? See Major Technique 1, Infrared Spectroscopy.

17.56 Normal water, H_2O, is necessary for life, but heavy water, D_2O, is toxic. Suggest a reason for this difference. The pK_a of deuterium oxide is 14.955 at 25°C.

17.57 The biological half-life of a radioisotope is the time required for the body to excrete half of the radioisotope. The *effective half-life* is the time required for the amount of a radioisotope in the body to be reduced to half its original amount, as a result of both the decay of the radioisotope and its excretion. Sulfur-35 ($t_{1/2}$ = 87.4 d) is used in cancer research. The biological half-life of sulfur-35 in the human body is 90. d. What is the effective half-life of sulfur-35?

17.58 Barium-140 ($t_{1/2}$ = 12.8 d) released in the fire at the Chernobyl nuclear plant has been found in some agricultural products in the region. The biological half-life of barium-140 in the human body is 65 d. What is the effective half-life (see Exercise 17.57) of barium-140?

Nuclear Energy

17.59 Calculate the energy in joules that is equivalent to (a) 1.0 g of matter; (b) one electron; (c) 1.0 pg of matter; (d) one proton.

17.60 Calculate the energy in joules that is equivalent to (a) 1.00 kg of matter; (b) 1.00 lb of matter (1 lb = 454 g); (c) one neutron; (d) one hydrogen atom.

17.61 The Sun emits radiant energy at the rate of 3.9×10^{26} J·s^{-1}. What is the rate of mass loss (in kilograms per second) of the Sun?

17.62 (a) For the fusion reaction $6\ D \longrightarrow 2\ ^4He + 2\ ^1H + 2\ n$, 3×10^8 kJ of energy is released by a certain sample of deuterium. What is the mass loss (in grams) for the reaction? (b) What was the mass of deuterium converted? The molar mass of deuterium is 2.014 g·mol^{-1}.

17.63 Calculate the binding energy per nucleon (J·nucleon^{-1}) for (a) ^{62}Ni, 61.928 346m_u; (b) ^{239}Pu, 239.0522m_u; (c) ^2H, 2.0141m_u; (d) ^3H, 3.016 05m_u. (e) Which nuclide is the most stable?

17.64 Calculate the binding energy per nucleon (J·nucleon^{-1}) for (a) ^{98}Mo, 97.9055m_u; (b) ^{151}Eu, 150.9196m_u; (c) ^{56}Fe, 55.9349m_u; (d) ^{232}Th, 232.0382m_u. (e) Which nuclide is the most stable?

17.65 Calculate the energy released per gram of starting material in the fusion reaction represented by each of the following equations.
(a) $D + D \longrightarrow\ ^3He + n$ (D, 2.0141m_u; ^3He, 3.0160m_u)
(b) $^3He + D \longrightarrow\ ^4He + ^1H$ (^1H, 1.0078m_u; ^4He, 4.0026m_u)
(c) $^7Li + ^1H \longrightarrow 2\ ^4He$ (^7Li, 7.0160m_u)
(d) $D + T \longrightarrow\ ^4He + n$ (T, 3.0160m_u)

17.66 Calculate the energy released per gram of starting material in the nuclear reaction represented by each of the following equations.
(a) $^7Li + ^1H \longrightarrow n + ^7Be$
(^1H, 1.0078m_u; ^7Li, 7.0160m_u; ^7Be, 7.0169m_u)
(b) $^{59}Co + D \longrightarrow\ ^1H + ^{60}Co$
(^{59}Co, 58.9332m_u; ^{60}Co, 59.9529m_u; D, 2.0141m_u)
(c) $^{40}K + \beta \longrightarrow\ ^{40}Ar$ (^{40}K, 39.9640m_u; ^{40}Ar, 39.9624m_u; β, 0.0005m_u)
(d) $^{10}B + n \longrightarrow\ ^4He + ^7Li$ (^{10}B, 10.0129m_u; ^4He, 4.0026m_u)

17.67 Sodium-24 (23.990 96m_u) decays to magnesium-24 (23.985 04m_u). (a) Write a nuclear equation for the decay. (b) Determine the change in energy that accompanies the decay. (c) Calculate the change in the binding energy per nucleon.

17.68 (a) How much energy is emitted in each α decay of plutonium-234? (^{234}Pu, 234.0433m_u; ^{230}U, 230.0339m_u). (b) The half-life of plutonium-234 is 8.8 h. How much heat is released by the α decay of a 1.00-μg sample of plutonium-234 in a 24-h period?

17.69 Each of the following equations represents a fission reaction. Complete and balance the equations:
(a) $^{244}_{95}Am \longrightarrow\ ^{134}_{53}I + ^{107}_{42}Mo + 3\ ?$
(b) $^{235}_{92}U + ^1_0n \longrightarrow\ ? + ^{138}_{52}Te + 2\ ^1_0n$
(c) $^{235}_{92}U + ^1_0n \longrightarrow\ ^{101}_{42}Mo + ^{132}_{50}Sn + ?$

17.70 Complete each of the following nuclear equations for fission reactions:
(a) $^{239}_{94}Pu + ^1_0n \longrightarrow\ ^{98}_{42}Mo + ^{138}_{52}Te + ?$
(b) $^{239}_{94}Pu + ^1_0n \longrightarrow\ ^{100}_{43}Tc + ? + 4\ ^1_0n$
(c) $^{239}_{94}Pu + ^1_0n \longrightarrow\ ? + ^{139}_{49}In + 3\ ^1_0n$

Integrated Exercises

17.71 State whether the following statements are true or false. If false, explain why. (a) The dose equivalent is lower than the actual dose of radiation because it takes into account the differential effects of different types of radiation. (b) Exposure to 1×10^8 Bq of radiation would be much more hazardous than exposure to 10 Ci of radiation. (c) Spontaneous radioactive decay follows first-order kinetics. (d) Fissile nuclei can undergo fission when struck with slow neutrons, whereas fast neutrons are required to split fissionable nuclei.

17.72 State whether the following statements are true or false. If false, explain why. (a) A subcritical mass of fissionable material is unstable and likely to explode. (b) In order for fusion to occur, the colliding particles must have high kinetic energy. (c) Highly reactive fission products are considered to be no longer dangerous after two half-lives. (d) The larger the binding energy per nucleon, the more stable is the nucleus.

17.73 (a) How many radon-222 nuclei ($t_{1/2}$ = 3.82 d) decay per minute to produce an activity of 4 pCi? (b) A bathroom in the basement of a home measures 2.0 m × 3.0 m × 2.5 m. If the activity of radon-222 in the room is 4.0 $pCi{\cdot}L^{-1}$, how many nuclei decay during a shower lasting 5.0 min?

17.74 Tritium undergoes β decay, and the emitted β particle has an energy of 0.0186 MeV (1 MeV = 1.602×10^{-13} J). If a 1.0-g sample of tissue absorbs 10% of the decay products of 1.0 mg of tritium, what dose equivalent does the tissue absorb?

17.75 It is found that 2.0×10^{-5} mol ^{222}Rn ($t_{1/2}$ = 3.82 d) has seeped into a closed basement with a volume of 2.0×10^3 m^3. (a) What is the initial activity of the radon in picocuries per liter ($pCi{\cdot}L^{-1}$)? (b) How many atoms of ^{222}Rn will remain after 1 day (24 h)? (c) How long will it take for the radon to decay to below the EPA recommended level of 4 $pCi{\cdot}L^{-1}$?

17.76 Explain why containers of radioactive waste are more susceptible to corrosion than containers of nonradioactive waste with the same chemical reactivity.

17.77 Uranium-238 decays through a series of α and β emissions to lead-206, with an overall half-life for the entire process of 4.5 Ga. How old is a uranium-bearing ore that is found to have a $^{238}U/^{206}Pb$ ratio of (a) 1.00 and (b) 1.25?

17.78 A planet on which life is based on silicon instead of carbon has been discovered. However, a meteor strike destroyed most of the life on the planet. To determine how long ago the meteor strike occurred, the activity of silicon-32, which has a half-life of 1.6×10^2 a, was measured in samples from the fossil remains of life forms killed in the meteor strike and in existing life forms. Activity in the fossil samples was found to be 0.015% of the activity in the living samples. How long ago did the meteor strike occur?

17.79 Sodium-24 is used for monitoring blood circulation. (a) If 2.0 mg of sodium-24 has an activity of 17.3 Ci, what is its decay constant and its half-life? (b) What mass of the sodium-24 sample remains after 2.0 d? The mass of a sodium-24 atom is $24m_u$.

17.80 A radioactive sample contains ^{32}P (half-life, 14.28 d), ^{33}S (half-life, 87.2 d), and ^{59}Fe (half-life, 44.6 d). After 90 d, a sample that originally weighed 8.00 g contains 0.0254 g of ^{32}P, 1.466 g of ^{33}S, and 0.744 g of ^{59}Fe. What was the percentage composition (by mass) of the original sample?

17.81 Radiopharmaceuticals have one of two general functions: (1) they may be used to *detect* or *image* biological problems such as tumors and (2) they may be used to *treat* an illness. Which type of radiation (α, β, or γ) would be the most suitable for (a) detection and (b) therapy? Justify your selections. (c) From standard literature sources, find at least two radionuclides that have been used for imaging body tissues. (d) What are the half-lives of these radionuclides? See Box 17.1.

17.82 Radioactive metal ions that have short half-lives are being intensely studied as pharmaceuticals. The strategy is to attach a well-designed ligand to the metal ion so that the complex very selectively aggregates in one particular type of body tissue. What properties of the ligand are important to the design of effective radiopharmaceutical therapeutic agents? See Box 17.1.

17.83 Technetium-99m is produced by a sequence of reactions in which molybdenum-98 is bombarded with neutrons to form molybdenum-99, which undergoes β decay to technetium-99m. (a) Write the balanced nuclear equations for this sequence. (b) Compare the neutron-to-proton ratio of the final daughter product with that of technetium-99m. Which is closer to the band of stability?

17.84 Actinium-225 decays by successive emission of three α particles. (a) Write the nuclear equations for the three decay processes. (b) Compare the neutron-to-proton ratio of the final daughter product with that of actinium-225. Which is closer to the band of stability?

17.85 Some airports have installed radiation detectors so that radioactive materials which could be used to make a bomb can be detected. The 12-year old boy next door asks you to explain how such a large object as a nuclear bomb could be carried on an airplane. Explain in words a 12-year old would understand what materials would have to be transported, what minimum mass of radioactive material would be required (the critical mass), and what the volume of that minimum mass would be.

17.86 A nuclear waste storage facility is being proposed for your county and you have been asked to prepare a recommendation for how highly radioactive fission products should be processed and stored. In your recommendation discuss the benefits and drawbacks of at least three modes of nuclear waste storage.

17.87 What volume of helium at 1.0 atm and 298 K will be collected if 2.5 g of ^{222}Rn is stored in a container able to expand to maintain constant pressure for 15 d? (^{222}Rn decays to ^{218}Po with a half-life of 3.824 d.)

17.88 Why is the boiling point of heavy water greater than that of ordinary water? (a) Propose a model that allows you to estimate the difference or, from the known difference, to estimate any unknown parameters in the model. (b) Use your model to estimate the boiling point of "extraheavy water," T_2O.

17.89 A positron has the same mass as that of an electron, but the opposite charge. When a positron emitted in a PET scan encounters an electron, annihilation occurs in the body: electromagnetic energy is produced and no matter remains. How much energy (in joules) is produced in the encounter? See Box 17.1.

17.90 Do nuclei that are positron emitters lie above or below the band of stability? Which of the following isotopes might be suitable for PET scans? Explain your reasoning and write the equation for the decay: (a) ^{18}O; (b) ^{13}N; (c) ^{11}C; (d) ^{20}F; (e) ^{15}O. See Box 17.1.

17.91 The radioactivity from a sample of $Na_2{}^{14}CO_3$ was measured by noting the time required for the count of disintegrations to reach 8000. Five times were recorded: 21.25, 23.46, 20.97, 22.54, and 23.01 min. Background radiation was measured by noting the time required for 500 counts to be registered. Three times were recorded: 5.26, 5.12, and 4.95 min. What is the average level of radioactivity in the $Na_2{}^{14}CO_3$ sample, corrected for background radiation, in (a) disintegrations per minute; (b) microcuries?

17.92 (a) Using a standard graphing program such as that found on the Web site for this text, plot the fraction of ^{14}C remaining in a 4.00×10^4-year-old archaeological sample as a function of time. For convenience, use intervals of 1000 a.

(b) Plot the natural logarithm of the fraction of ^{14}C remaining as a function of time. (c) After what period of time will less than 1.00% of the original ^{14}C in the sample remain?

Chemistry Connections

17.93 A person with pernicious anemia lacks "intrinsic factor," a compound required for the absorption of vitamin B_{12} and its storage in the liver. The diagnosis is confirmed with the Schilling test. In this test the patient is given a small dose of vitamin B_{12} labeled with radioactive ^{57}Co or ^{58}Co, followed by a saturating dose of nonlabeled B_{12}, which releases the stored B_{12}. If the patient has intrinsic factor, a 24-hour urine sample will contain 13−15% of the labeled B_{12}. If intrinsic factor is absent, less than 6% will be excreted. The patient is then given instrinsic factor and the test is repeated for comparison. In one administration of the Schilling test, the patient was given a capsule containing 0.5 μCi of $^{58}CoB_{12}$, followed by 1.0 mg of nonlabeled B_{12}. 1200 mL of urine was collected over the next 24 hours. A 3.0-mL sample of the urine gave 83 cpm (counts per minute) and a 3.0-mL standard sample containing 0.4 nCi per mL gave 910 cpm. The test was repeated one week later with the administration of 30. mg of intrinsic factor. The 3.0-mL sample of urine from the second test gave 120 cpm. The half-life of ^{58}Co is 72 days.

(a) Calculate the percentage of ^{58}Co excreted with and without the intrinsic factor. Assume that the first test did not contaminate the second test.

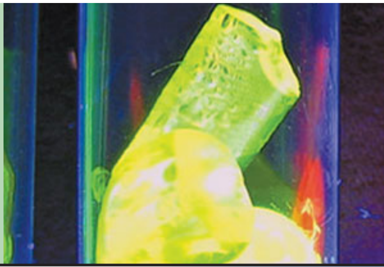
(b) What would be the activity of the $^{58}CoB_{12}$ in the original capsule if it were stored for 7 days?

(c) If the biological half-life of B_{12} is 180 days, what is the effective half-life of $^{58}CoB_{12}$ in the body? See Exercise 17.57.

(d) Use the effective half life of $^{58}CoB_{12}$ to determine what fraction of the counts in the second test would be due to the dose given in the first test.

(e) The radioisotope ^{58}Co decays to another radioisotope, ^{59}Fe. The total mass of iron in the patient was 2.5 g. If all the ^{59}Fe produced in the first test were incorporated into hemoglobin, what percentage of the total iron would be ^{59}Fe the day after the first test? Ignore the decay of ^{59}Fe.

ORGANIC CHEMISTRY I: THE HYDROCARBONS



What Are the Key Ideas? Large numbers of different hydrocarbons arise from the ability of carbon atoms to form long chains and rings with one another; the types of carbon–carbon bonds present give the hydrocarbons characteristic properties.

Why Do We Need to Know This Material? All life on Earth is based on carbon; so is the fuel we burn, our food, and the clothes we wear. Therefore, to understand a major part of the everyday world, we need to be familiar with the chemistry of this extraordinary element. Compounds of carbon and hydrogen are the foundation of the petrochemical industry; petroleum products are used to generate electricity and to heat our homes. They are also used to make the flexible, strong polymeric and composite materials that make modern communication and transportation possible.

What Do We Need to Know Already? This chapter draws on the introduction to organic formulas and nomenclature in Sections C and D, the structure of molecules (Chapters 2 and 3), intermolecular forces (Sections 5.3–5.5), reaction enthalpy (Section 7.13), reaction mechanisms (Sections 14.7–14.9), and isomers (Section 16.7).

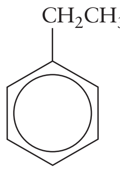
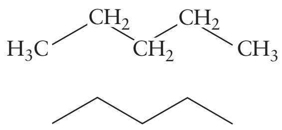
18.7 Nomenclature of Arenes
18.8 Electrophilic Substitution
IMPACT ON TECHNOLOGY: FUELS
18.9 Gasoline
18.10 Coal

Two elements, carbon and hydrogen, are the basis of nearly all our fuels, including not only petroleum products but their alternatives. Carbon, the focus of this chapter and the next, is also the basis of many materials essential to modern technology. Understanding the compounds that carbon forms and their reactions is therefore important not only to our technological and medical advances but also to our very survival. Carbon forms such a huge variety of compounds that an entire field of chemistry, organic chemistry, is devoted to its study. Carbon atoms are so adaptable because they can string together to form chains and rings of endless variety. This versatility allows the element to form thousands of complicated biomolecules that contribute to the structure and function of every organism on Earth. Synthetic carbon-based materials also have a wide range of properties, from the softness of fabrics and artificial skin to the tough composite materials used in experimental aircraft.

This chapter deals with **hydrocarbons,** compounds built from only carbon and hydrogen. There are two broad classes of hydrocarbons: an **aromatic hydrocarbon** has a benzene ring as a part of its molecular structure; an **aliphatic hydrocarbon** does not. The compound shown as (**1**) is aromatic; compound (**2**) is aliphatic. We can describe more complex molecules as having an "aromatic region" consisting of benzenelike rings and an "aliphatic region" containing chains of carbon atoms. In Chapter 19, we shall see that aromatic and aliphatic hydrocarbons can be regarded as the basic framework for all organic compounds.



1 Ethylbenzene, $C_6H_5CH_2CH_3$



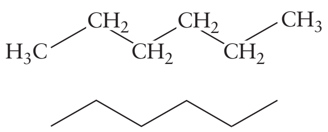
2 Pentane, C_5H_{12}

ALIPHATIC HYDROCARBONS

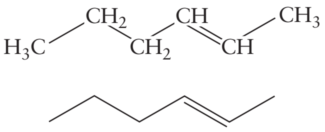
The different types of aliphatic hydrocarbons are distinguished by the type of bonding between the carbon atoms, such as whether all the bonds are single or whether some are multiple. The types of bonds determine the types of reactions that the hydrocarbon can undergo.

18.1 Types of Aliphatic Hydrocarbons

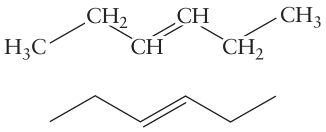
A **saturated hydrocarbon** is an aliphatic hydrocarbon with no multiple carbon–carbon bonds; an **unsaturated hydrocarbon** has one or more double or triple carbon–carbon bonds. More hydrogen atoms can be added to compounds in which there are multiple bonds, but compounds with only single bonds are "saturated" with hydrogen. Compound (**3**) is saturated; compounds (**4**) and (**5**) are unsaturated.



3 Hexane, C_6H_{14}



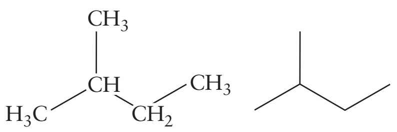
4 2-Hexene, C_6H_{12}



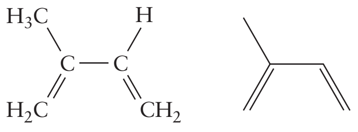
5 3-Hexene, C_6H_{12}

Because many organic molecules are very complicated, we need a simple way to represent their structures. It is often sufficient to give a **condensed structural formula,** which shows how the atoms are grouped together (see Section C). For instance, we write $CH_3CH_2CH_2CH_3$ for butane and $CH_3CH(CH_3)CH_3$ for methylpropane. The parentheses around the CH_3 group show that it is attached to the carbon atom on its left (or, if the formula begins with the parenthetical group, the carbon atom on its right). When several groups of atoms are repeated, we collect them together; so we can write butane as $CH_3(CH_2)_2CH_3$ and methylpropane as $(CH_3)_3CH$.

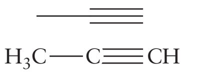
A line structure (introduced in Section C) represents a chain of carbon atoms as a zigzag line. The end of each short line in the zigzag represents a carbon atom. Because carbon nearly always has a valence of 4 in organic compounds, we do not need to show the C—H bonds. We just fill in the correct number of hydrogen atoms mentally, as we see for methylbutane (**6**), isoprene (**7**), and propyne (**8**). As explained in Section 2.7, a benzene ring is represented by a circle inside a hexagon, and we need to remember that one hydrogen atom is attached to each carbon atom.



6 Methylbutane, $(CH_3)_2CHCH_2CH_3$



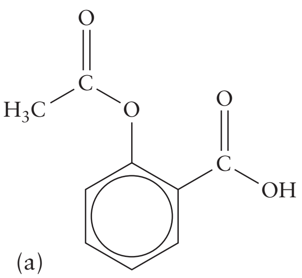
7 Isoprene, $CH_2{=}C(CH_3)CH{=}CH_2$



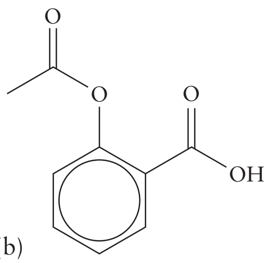
8 Propyne, $CH_3C{\equiv}CH$

Self-Test 18.1A Draw (a) the line structure of aspirin (**9a**) and (b) the structural formula for $CH_3(CH_2)_2C(CH_3)_2CH_2C(CH_3)_3$.

[***Answer:*** (a) (**9b**); (b) (**10**)]

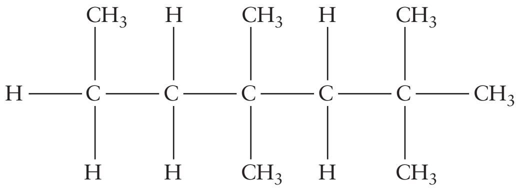


(a)



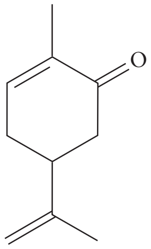
(b)

9 Acetylsalicylic acid (aspirin)

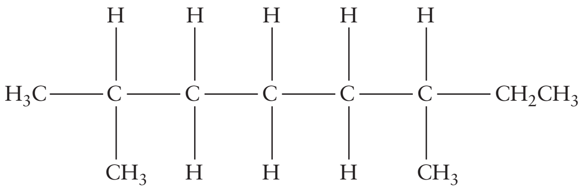


10

Self-Test 18.1B Write (a) the structural formula of carvone (**11a**) and (b) the condensed structural formula for (**11b**).

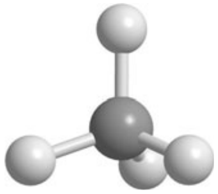


11a Carvone

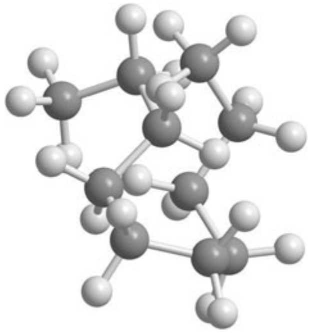


11b

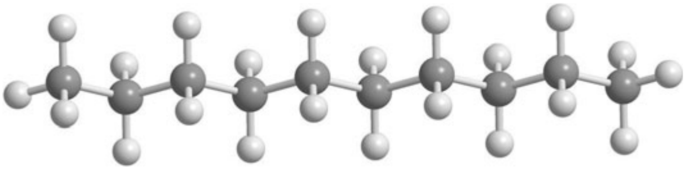
Saturated hydrocarbons are called **alkanes.** As we saw in Section 3.5, the bonds to each carbon atom in an alkane are single bonds that lie in a tetrahedral arrangement, with sp^3 hybridization. The simplest alkane is methane, CH_4 (**12**). The formulas of other alkanes are derived from CH_4 by inserting CH_2 groups between pairs of atoms. Although we write alkanes in two dimensions as linear structures with 90° angles, as in (**11b**), they really consist of tetrahedral arrangements of bonds at each carbon atom. Moreover, because all the C—C bonds are single, the different parts of an alkane molecule can rotate relative to each other. In liquids and gases, the chains of atoms in an alkane molecule are in constant motion, at some instants rolled up into a ball (**13**) and at others stretched out into a zigzag (**14**).



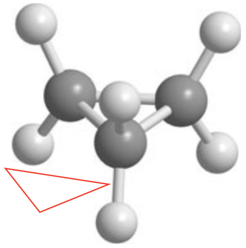
12 Methane, CH_4



13 Decane, $C_{10}H_{22}$



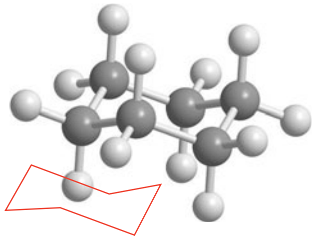
14 Decane, $C_{10}H_{22}$



15 Cyclopropane, C_3H_6

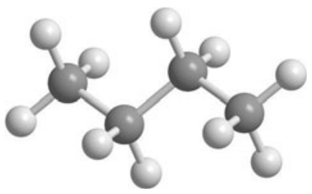
To name an alkane in which the carbon atoms form a single chain, we combine a prefix denoting the number of carbon atoms with the suffix *-ane* (Table 18.1). For example, CH_3—CH_3 (more simply, CH_3CH_3) is ethane and CH_3—CH_2—CH_3 (that is, $CH_3CH_2CH_3$) is propane. Cyclopropane, C_3H_6 (**15**), and cyclohexane, C_6H_{12} (**16**), are **cycloalkanes,** alkanes that contain rings of carbon atoms.

With C_4H_{10}, we find another reason for the variety of compounds that carbon can form: the same atoms can bond together in different arrangements. Four carbon atoms can link together in a chain to form butane (**17**) or in a Y-shape to form methylpropane (**18**). As we saw in Section 16.7, different compounds with the same molecular formula are called **isomers.** Thus, butane and methylpropane are isomers with the same molecular formula, C_4H_{10}.

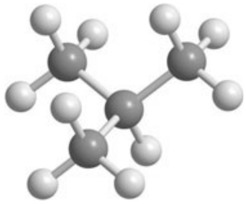


16 Cyclohexane, C_6H_{12}

The name "isomer" comes from the Greek words for "equal parts," suggesting that isomers are built from the same kit of parts.



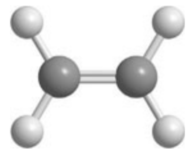
17 Butane, C_4H_{10}



18 Methylpropane, C_4H_{10}

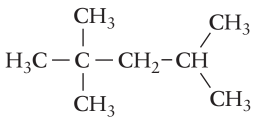
TABLE 18.1 Alkane Nomenclature

Number of carbon atoms	Formula	Name of alkane	Name of alkyl group	Formula
1	CH_4	methane	methyl	CH_3—
2	CH_3CH_3	ethane	ethyl	CH_3CH_2—
3	$CH_3CH_2CH_3$	propane	propyl	$CH_3CH_2CH_2$—
4	$CH_3(CH_2)_2CH_3$	butane	butyl	$CH_3(CH_2)_2CH_2$—
5	$CH_3(CH_2)_3CH_3$	pentane	pentyl	$CH_3(CH_2)_3CH_2$—
6	$CH_3(CH_2)_4CH_3$	hexane	hexyl	$CH_3(CH_2)_4CH_2$—
7	$CH_3(CH_2)_5CH_3$	heptane	heptyl	$CH_3(CH_2)_5CH_2$—
8	$CH_3(CH_2)_6CH_3$	octane	octyl	$CH_3(CH_2)_6CH_2$—
9	$CH_3(CH_2)_7CH_3$	nonane	nonyl	$CH_3(CH_2)_7CH_2$—
10	$CH_3(CH_2)_8CH_3$	decane	decyl	$CH_3(CH_2)_8CH_2$—
11	$CH_3(CH_2)_9CH_3$	undecane	undecyl	$CH_3(CH_2)_9CH_2$—
12	$CH_3(CH_2)_{10}CH_3$	dodecane	dodecyl	$CH_3(CH_2)_{10}CH_2$—



19 Ethene, C_2H_4

20 Ethyne, C_2H_2



21

The simplest unsaturated hydrocarbon is ethene, C_2H_4 or $H_2C{=}CH_2$, commonly called ethylene (**19**). It is the parent of the **alkenes,** a series of compounds with formulas derived from $H_2C{=}CH_2$ by inserting CH_2 groups. For example, the next member of the family is propene, H—CH_2—CH=CH_2 (more simply, $CH_3CH{=}CH_2$). The name of an alkene is the same as the name of the corresponding alkane, except that it ends in *-ene*. The location of the double bond is specified by numbering the carbon atoms in the chain and writing the lower of the two numbers of the carbon atoms joined by the double bond. Thus, $CH_3CH_2CH{=}CH_2$ is 1-butene and $CH_3CH{=}CHCH_3$ is 2-butene (see Toolbox 18.1). The term alkene also includes hydrocarbons with more than one double bond, as in $CH_2{=}CH{-}CH{=}CH_2$, 1,3-butadiene.

The **alkynes** are hydrocarbons that have at least one carbon–carbon triple bond. The simplest is ethyne, HC≡CH, which is commonly called acetylene (**20**). Alkynes are named like the alkenes but with the suffix *-yne*.

TOOLBOX 18.1 HOW TO NAME ALIPHATIC HYDROCARBONS

CONCEPTUAL BASIS

Because the types of carbon–carbon bonds present in the molecule tend to dominate its properties, an aliphatic hydrocarbon is first classified as an alkane, alkene, or alkyne. Then the longest chain of carbon atoms is used to form the "root" of the name. Other hydrocarbon groups attached to the longest chain are named as side chains.

PROCEDURE

The following rules for naming hydrocarbons have been adopted by the International Union for Pure and Applied Chemistry (IUPAC).

Alkanes

The names of straight-chain alkanes are given in Table 18.1: they all end in *-ane*. Name a hydrocarbon side chain as a substituent by changing the ending *-ane* to *-yl* (as in the last two columns in Table 18.1).

Example: CH_3CH_2— is the ethyl group

The names of branched-chain hydrocarbons and hydrocarbon derivatives are based on the name of the *longest* continuous carbon chain in the molecule (which might not be shown in a horizontal line).

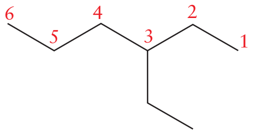
Example:  is a methylbutane

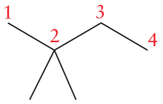
A cyclic (ring) hydrocarbon is designated by the prefix *cyclo-*.

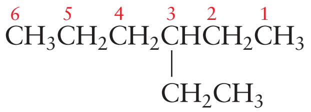
Example:  is cyclopropane

To indicate the position of a branch or substituent, the carbon atoms in the longest chain are numbered consecutively from one end to the other, starting at the end that will give the *lower* number(s) to the substituent(s).

Examples:





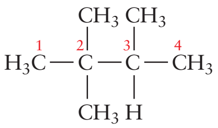


3-Ethylhexane

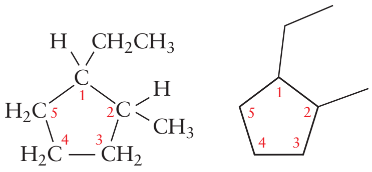
2,2-Dimethylbutane

The prefixes *di-*, *tri-*, *tetra-*, *penta-*, *hexa-*, and so on, indicate how many of each substituent are in the molecule. Numbers set off by hyphens specify to which carbon atoms the groups are attached.

Examples:



2,2,3-Trimethylbutane



1-Ethyl-2-methylcyclopentane

The substituents are listed in alphabetical order (disregarding the Greek prefixes) and attached to the root name. The names of substituents other than hydrocarbon groups are discussed more fully in Chapter 19 (see Toolbox 19.1).

Example 18.1 demonstrates how to name alkanes.

Alkenes and alkynes

Double bonds in hydrocarbons are indicated by changing the suffix *-ane* to *-ene*, and triple bonds are indicated by changing the suffix to *-yne*. The position of the multiple bond is given by the number of the first (lower-numbered) carbon atom involved in the multiple bond. If more than one multiple bond of the same type is present, the number of these bonds is indicated by a Greek prefix. Then follow the rules for naming alkanes.

Examples:

$$CH_3{-}CH_2{-}CH_2{-}C{\equiv}CH$$

1-Pentyne

$$CH_3{-}CH_2{-}CH{=}CH{-}CH_3$$

2-Pentene

$$CH_2{=}CH{-}CH_2{-}CH{=}CH_2$$

1,4-Pentadiene

When numbering atoms in the chain, the lowest numbers are given preferentially to (a) groups of atoms named by suffixes (see Toolbox 19.1), (b) double bonds, (c) triple bonds, and (d) groups named by prefixes.

Example 18.2 illustrates how to name alkenes.

EXAMPLE 18.1 Naming alkanes and cycloalkanes

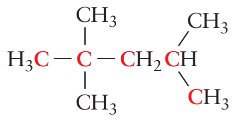
(a) Name the compound shown as (**21**) and (b) write the structural formula of 2-ethyl-1,1-dimethylcyclohexane.

PLAN Use the procedure in Toolbox 18.1.

SOLVE

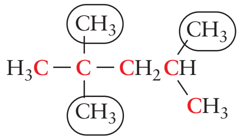
(a) Count carbon atoms in the longest chain.

*The longest carbon chain (in red) of (**21**) has 5 carbon atoms. the molecule is a substituted pentane.*



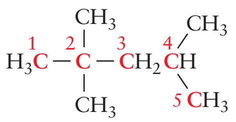
Identify and count substituents.

There are 3 methyl groups (CH_3—) on the longest chain. The molecule is a trimethylpentane.



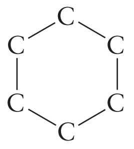
Number the backbone carbon atoms to give the lowest numbers to the substituents.

2,2,4-trimethylpentane



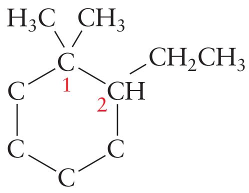
(b) Draw the longest chain of carbon atoms first.

"Cyclohexane" tells us that the molecule has a ring of 6 carbon atoms.

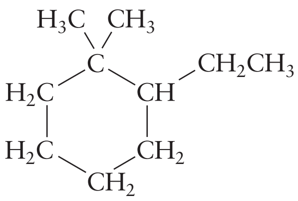


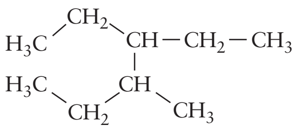
Number the carbon atoms and add the substituents according to the numbers given in the name.

Add 2 methyl groups to one carbon atom, which becomes carbon atom 1. Then add an ethyl group to carbon atom 2.



Add hydrogen atoms as needed to give each carbon atom a valence of four.

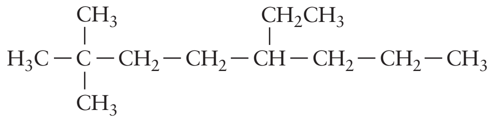




22

Self-Test 18.2A (a) Name the compound shown as (**22**) and (b) write the structural formula of 5-ethyl-2,2-dimethyloctane.

[***Answer:*** (a) 3-Ethyl-4-methylhexane; (b) (**23**)]



23

Self-Test 18.2B Name the compound $(CH_3)_2CHCH_2CH(CH_2CH_3)_2$ and write the structural formula of 3,3,5-triethylheptane.

EXAMPLE 18.2 Naming alkenes

(a) Name the alkene $CH_3CH_2CH{=}CH_2$ and (b) write the condensed structural formula for 5-methyl-1,3-hexadiene.

PLAN Use the procedure in Toolbox 18.1.

SOLVE (a) From Toolbox 18.1, $CH_3CH_2CH{=}CH_2$ is 1-butene (not 3-butene). (b) 5-Methyl-1,3-hexadiene has two double bonds, at the first and third carbon atoms, with a methyl group on the fifth carbon atom: $CH_2{=}CHCH{=}CHCH(CH_3)CH_3$.

Self-Test 18.3A (a) Name the alkene $(CH_3)_2CHCH{=}CH_2$ and (b) write the condensed structural formula for 2-methylpropene.

[***Answer:*** (a) 3-Methyl-1-butene; (b) $CH_2{=}C(CH_3)_2$]

Self-Test 18.3B (a) Name the alkene $(CH_3CH_2)_2CHCH{=}CHCH_3$ and (b) write the structural formula for cyclopropene.

Saturated hydrocarbons have only single bonds; unsaturated hydrocarbons have one or more multiple bonds. Alkanes are saturated hydrocarbons. Alkenes and alkynes are unsaturated hydrocarbons: the former have carbon–carbon double bonds and the latter have triple bonds.

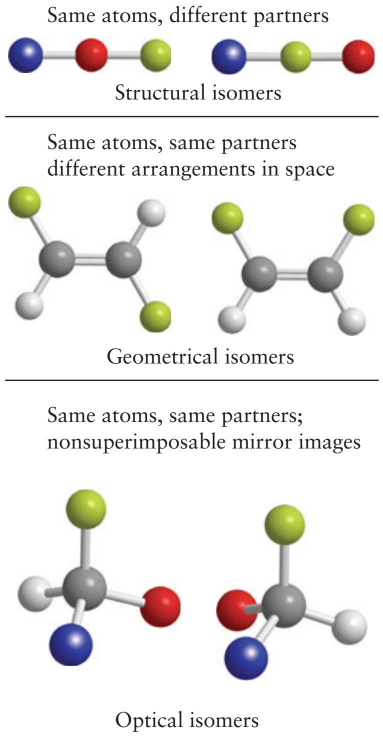


FIGURE 18.1 A summary of the types of isomerism in organic compounds.

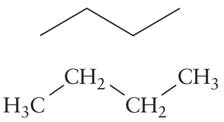
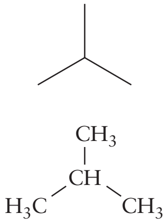
18.2 Isomers

Figure 18.1 summarizes the types of isomerism that are found in organic compounds. Molecules that are **structural isomers** are built from the same atoms, but the atoms are connected differently; that is, the molecules have a different **connectivity.** For example, we can insert a $-CH_2-$ group into the C_3H_8 molecule in two different ways to give two different compounds with the formula C_4H_{10}:

Although the $-CH_2-$ group could be inserted in other places, the free rotation about single C–C bonds in hydrocarbons allows the resulting molecules to be twisted into one or the other of these two isomers. Both compounds are gases, but butane (**24**) condenses at -1°C, whereas methylpropane (**25**) condenses at -12°C. Two molecules that differ only by rotation about one or more bonds may look different on paper, but they are not isomers of each other; they are different **conformations** of the same molecule. Example 18.3 illustrates how to tell if two molecules are different isomers or different conformations of the same isomer.



24 Butane, C_4H_{10}



25 Methylpropane, C_4H_{10}

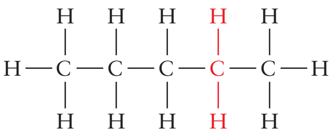
EXAMPLE 18.3 Writing the formulas of structural isomers

Draw two-dimensional structural formulas for all the isomeric alkanes of formula C_5H_{12}.

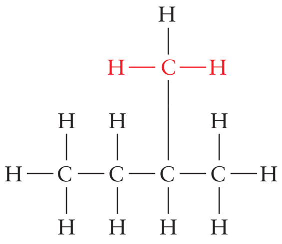
PLAN Isomers cannot be changed into one another simply by rotating either the entire formula or parts of the formula on the page. One approach is to insert $-CH_2-$ groups into different parts of the formulas of the two C_4H_8 molecules given earlier (as **24** and **25**), then discard formulas that repeat those already obtained. It is often easier to identify different conformations of the same isomer by building molecular models that allow rotation about single bonds.

SOLVE

From butane, we can form

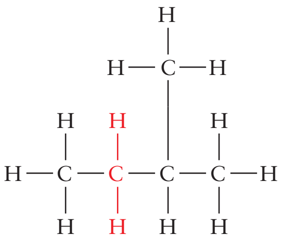


(a)

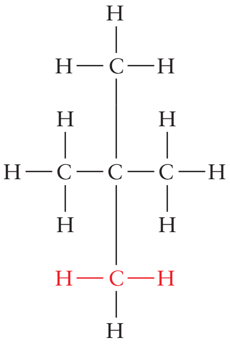


(b)

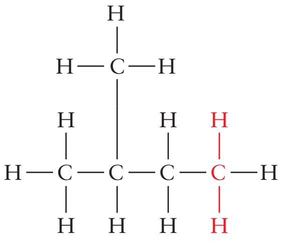
From methylpropane, we can form



(c)



(d)



(e)

Molecules (b) and (c) are identical. The atoms of molecule (e) are joined together in the same arrangement as that in (b) and (c), but the structure looks different because it has been rotated 180° and twisted; so (b), (c), and (e) are the same. There are therefore only three distinct isomers with formula C_5H_{12}: (a), (b), and (d).

Self-Test 18.4A Write the condensed structural formulas for the five isomeric alkanes of molecular formula C_6H_{14}.

[***Answer:*** $CH_3(CH_2)_4CH_3$; $CH_3(CH_2)_2CH(CH_3)CH_3$; $CH_3CH_2CH(CH_3)CH_2CH_3$; $CH_3CH_2C(CH_3)_2CH_3$; $CH_3CH(CH_3)CH(CH_3)CH_3$]

Self-Test 18.4B Halogen atoms can substitute for hydrogen atoms in hydrocarbons. Write the condensed structural formulas for the four isomers with the molecular formula C_4H_9Br.

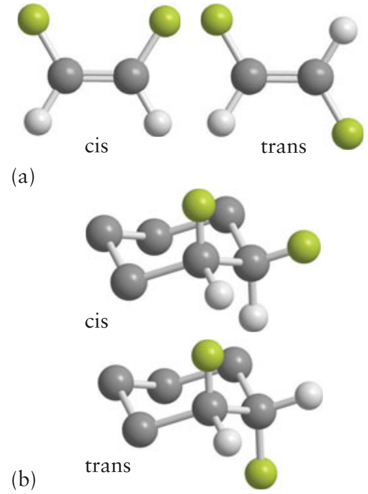


FIGURE 18.2 Two pairs of geometrical isomers. In geometrical isomerism two groups take different positions across a double bond, as in part (a); or different positions above and below a ring, as in part (b). Note that the neighbors of each atom in a pair of isomers are the same, but the arrangement of the atoms in space is different. (The compound in part (a) is 2-butene when the green sphere is CH_3 and the white sphere is H.)

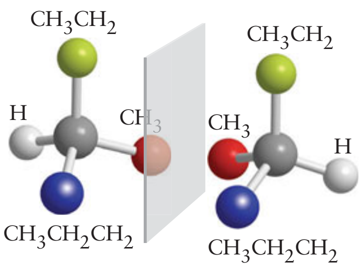

FIGURE 18.3 The molecule of 3-methylhexane on the right is the mirror image of the one on the left. Each group is represented by a sphere of a different color. The molecule on the left cannot be superimposed on the one on the right, and so these two molecules are distinct optical isomers.

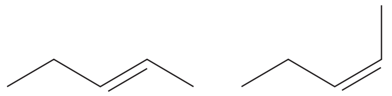
In **stereoisomers,** the molecules have the same connectivity but the atoms are arranged differently in space. One class of stereoisomers are **geometrical isomers,** in which atoms have different arrangements on either side of a double bond or above and below the ring of a cycloalkane or cycloalkene (Fig. 18.2). Geometrical isomers of organic molecules are distinguished by the prefixes *cis*- and *trans*-. For example, in the upper part of the illustration, we can see that there are two different 2-butenes: in the cis isomer both methyl groups are on the same side of the double bond and in the trans isomer the methyl groups are across the double bond. Geometrical isomers have the same molecular formula and structural formula but different properties.

Self-Test 18.5A Identify (**26a**) and (**26b**) as cis or trans.

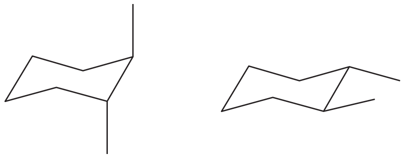
[***Answer:*** (**26a**) is *trans*-2-pentene; (**26b**) is *cis*-2-pentene]

Self-Test 18.5B Identify (**27a**) and (**27b**) as cis or trans.



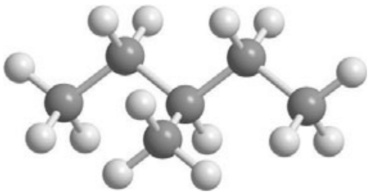
(a) (b)

26



(a) (b)

27



28 3-Methylpentane, C_6H_{14}

Another type of stereoisomerism is optical isomerism. **Optical isomers** are each other's nonsuperimposable mirror images. To understand this definition, consider 3-methylhexane, $CH_3CH_2CH(CH_3)CH_2CH_2CH_3$, and its mirror image (Fig. 18.3). No matter how we twist and turn the molecules, we cannot superimpose the mirror-image molecule on the original molecule. It is like trying to superimpose your right hand on your left hand. A **chiral molecule,** such as 3-methylhexane, is a molecule that is not identical to its mirror image. A chiral molecule and its mirror image form a pair of **enantiomers,** or mirror-image isomers. Although they have the same composition, the two enantiomers are, in fact, two distinct compounds. In organic compounds, optical isomers occur whenever four different groups are attached to the same carbon atom, which is then called a "chiral carbon atom." The alkane 3-methylpentane (**28**), does not have a chiral carbon atom. It is an example of an **achiral molecule,** a molecule that can be superimposed on its mirror image.

Enantiomers have identical chemical properties, except when they react with other chiral compounds. Because many biochemical substances are chiral, one consequence of this difference in reactivity is that enantiomers may have different odors and pharmacological activities. To be effective, the molecule has to fit into a cavity, or slot, of a certain shape, either in an odor receptor in the nose or in an enzyme. Only one member of the enantiomeric pair may be able to fit.

Enantiomers differ in one physical property: chiral molecules display optical activity, the ability to rotate the plane of polarization of light (Section 16.7 and Box 16.2). If a chiral molecule rotates the plane of polarization clockwise, then its mirror-image partner rotates it through the same angle in the opposite direction.

Often organic compounds synthesized in the laboratory are racemic mixtures, or mixtures of enantiomers in equal proportions (Section 16.7). In contrast, reactions in living cells commonly lead to only one enantiomer. It is a remarkable feature of nature that almost all naturally occurring amino acids in animals have the same handedness.

EXAMPLE 18.4 Deciding whether a compound is chiral

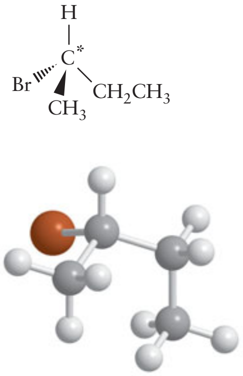
A bromoalkane is formed from an alkane when a bromine atom replaces a hydrogen atom. Decide whether the bromoalkanes (a) $CH_3CH_2CHBrCH_3$ and (b) $CH_3CHBrCH_3$ are chiral.

PLAN Identify carbon atoms as chiral if they have four different groups attached.

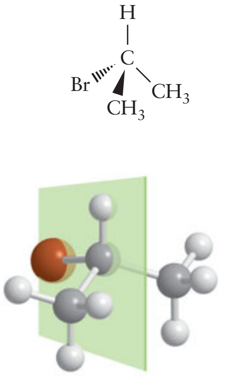
SOLUTION

Draw the compounds. Mark carbon atoms as chiral (*) if they have four different groups attached.

(a) $CH_3CH_2CHBrCH_3$



(b) $CH_3CHBrCH_3$



(a) The C atom marked * is attached to four different groups and hence is chiral; therefore the molecule is not superimposable on its mirror image. The molecule is chiral.
(b) No atom is chiral. The molecule is superimposable on its mirror image. The molecule is achiral.

A note on good practice: Dashed and solid wedge-shaped bonds are commonly used when displaying organic structures to convey a sense of the three-dimensional shapes. The dashed wedge-shaped bonds go into the page and the solid wedge-shaped bonds come toward us. The thin solid lines are in the plane of the paper.

Self-Test 18.6A A chlorofluorocarbon molecule contains Cl and F atoms as well as C and H. Which of the following chlorofluorocarbons is chiral: (a) CH_3CF_2Cl; (b) CH_3CHFCl; (c) CH_2FCl?

[***Answer:*** (b)]

Self-Test 18.6B In an alcohol, an —OH group is attached to a C atom. Which of the following alcohols is chiral: (a) CH_3CH_2OH; (b) $CH_3CH(OH)CH_3$; (c) $CH_3CH(OH)CH_2CH_3$?

Structural isomers have identical molecular formulas, but their atoms are linked to different neighbors. Geometrical isomers have the same molecular and structural formulas but different arrangements in space. Molecules with four different groups attached to a single carbon atom are chiral; they are optical isomers.

18.3 Properties of Alkanes

The electronegativities of carbon and hydrogen (2.6 and 2.2, respectively) are so similar and rotation about bonds so free that hydrocarbon molecules are best regarded as nonpolar. The dominant interaction between alkane molecules is therefore the London force (Section 5.4). Because the strength of this interaction increases with the number of electrons in the molecule, we can expect the alkanes in petroleum, their major source, to become less volatile with increasing molar mass and therefore to be separable by fractional distillation, as described in Section 9.19 (Fig. 18.4). The lightest members, methane through butane, are gases at room temperature. Pentane is a volatile liquid, and hexane through undecane ($C_{11}H_{24}$) are moderately volatile liquids that are present in gasoline, which is discussed further in Section 18.9. All alkanes are insoluble in water. Because their densities are lower than that of water, they float on the surface of water. Even a small oil spill at sea can form an organic layer on the surface of the ocean and spread over a huge area.

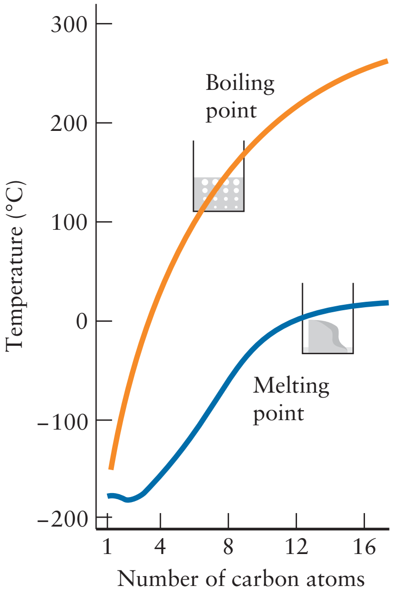


FIGURE 18.4 The melting and boiling points of the unbranched alkanes from CH_4 to $C_{16}H_{34}$.

Thinking point: How could you estimate the area that 1 L of gasoline might spread over on water?

Alkanes with long, unbranched chains tend to have higher melting points, boiling points, and enthalpies of vaporization than those of their branched isomers. The difference arises because, compared with unbranched molecules, the atoms of neighboring branched molecules cannot get as close together (Fig. 18.5). As a result, molecules with branched chains have weaker intermolecular forces than their unbranched isomers.

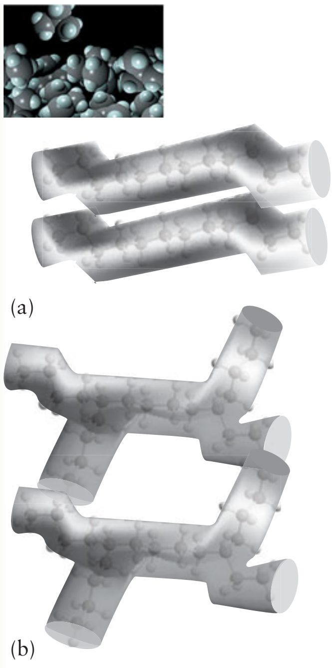

FIGURE 18.5 (a) The atoms in neighboring straight-chain alkanes, represented by the tubelike structures, can lie close together. (b) Fewer of the atoms of neighboring branched alkane molecules can get so close together overall, and so the London forces are weaker and branched alkanes are more volatile.

Animation 18.5

Self-Test 18.7A Which compound has the higher boiling point: (a) $CH_3CH_2CH_2CH_2CH_3$ or (b) $(CH_3)_2CHCH_2CH_3$? Why?

[***Answer:*** (a), because it is not branched and so has stronger London forces.]

Self-Test 18.7B Which compound has the higher boiling point: (a) $CH_3CH_2CH_2CH_2CH_3$ or (b) $CH_3CH_2CH_2CH_3$? Why?

The alkanes were once called the *paraffins*, from Latin words meaning "little affinity." As this name suggests, they are not very reactive. They are unaffected by concentrated sulfuric acid, by boiling nitric acid, by strong oxidizing agents such as potassium permanganate, and by boiling aqueous sodium hydroxide. One reason for their resistance to chemical onslaught is thermodynamic: the C–C and C—H bonds are strong (their mean bond enthalpies are 348 $kJ\cdot mol^{-1}$ and 412 $kJ\cdot mol^{-1}$, respectively), and so there is little energy advantage in replacing them with most other bonds. The most notable exceptions are C=O (743 $kJ\cdot mol^{-1}$), C—O (360 $kJ\cdot mol^{-1}$), and C—F (484 $kJ\cdot mol^{-1}$) bonds.

In addition to the catalyzed reactions used in the refining of petroleum (see Sections 18.5 and 18.9), alkanes undergo two common reactions: oxidation and substitution (Section 18.4). The alkanes are commonly used as fuels, because their combustion to carbon dioxide and water is highly exothermic (Section 7.17):

$$CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g) \qquad \Delta H^\circ = -890\ kJ$$

In this reaction, the strong carbon–hydrogen bonds are replaced by the even stronger O—H bonds (463 $kJ\cdot mol^{-1}$), and the oxygen–oxygen bond (496 $kJ\cdot mol^{-1}$) is replaced by two very strong C=O bonds. The excess energy is given off as heat.

The strength of the London forces between alkane molecules increases as the molar mass of the molecules increases; hydrocarbons with unbranched chains pack together more closely than their branched isomers and so it takes more energy to separate their molecules. Alkanes are not very reactive, but they do undergo oxidation (combustion) and substitution reactions.

18.4 Alkane Substitution Reactions

Alkanes are used as the raw materials for the synthesis of many more reactive compounds. Starting with alkanes obtained from the refining of petroleum, organic chemists introduce reactive groups of atoms into the molecules in the process called **functionalization.** The functionalization of alkanes can be achieved by a **substitution reaction,** a reaction in which an atom or group of atoms replaces an atom (in alkanes, a hydrogen atom) in the original molecule (Fig. 18.6). An example of a substitution reaction is that between methane and chlorine. A mixture of these two gases survives indefinitely in the dark but, when exposed to ultraviolet radiation or heated to more than 300°C, the gases react explosively:

$$CH_4(g) + Cl_2(g) \xrightarrow{\text{light or heat}} CH_3Cl(g) + HCl(g)$$

Chloromethane (CH_3Cl) is only one of the products; dichloromethane (CH_2Cl_2), trichloromethane ($CHCl_3$), and tetrachloromethane (CCl_4) also form, especially at high concentrations of chlorine.

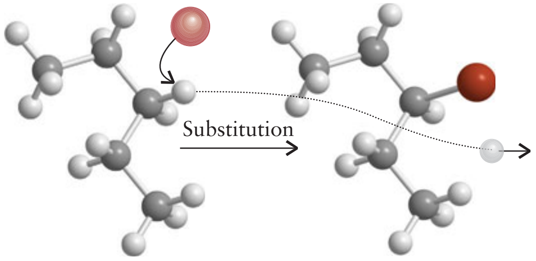

FIGURE 18.6 In an alkane substitution reaction, an incoming atom or group of atoms (represented by the red sphere) replaces a hydrogen atom in the alkane molecule.

The results of kinetic studies suggest that alkane substitution reactions typically proceed by a radical chain mechanism (Section 14.9). The *initiation* step in the chlorination of methane is the dissociation of chlorine:

$$Cl_2 \xrightarrow{\text{light or heat}} Cl\cdot + Cl\cdot$$

Chlorine atoms (each of which has one unpaired electron) are highly reactive; they attack methane molecules and extract a hydrogen atom, leaving a methyl radical behind:

$$Cl\cdot + CH_4 \longrightarrow HCl + \cdot CH_3$$

Recall from Section 2.9 that most radicals are very reactive. Because one of the products is another radical, this reaction is a *propagation* step (a step in which one reactive radical intermediate produces another). In a second propagation step, the methyl radical may react with a chlorine molecule:

$$Cl_2 + \cdot CH_3 \longrightarrow CH_3Cl + Cl\cdot$$

A *termination* step is reached when two radicals combine to form a nonradical product, as in

$$Cl\cdot + \cdot Cl \longrightarrow Cl_2$$

The product of substitution reactions of alkanes with the halogens is typically a complex mixture of *haloalkanes* (halogenated alkanes). One way to limit the production of the more highly substituted alkanes is to use a large excess of the alkane; then most reactions take place with the original hydrocarbon rather than with any haloalkanes produced in the reaction.

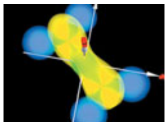
Alkane substitution takes place by a radical chain mechanism.

18.5 Properties of Alkenes

The carbon–carbon double bond in alkenes is more reactive than carbon–carbon single bonds and gives alkenes their characteristic properties. As we saw in Section 3.4, a double bond consists of a σ-bond and a π-bond. Each carbon atom in a double bond is sp^2 hybridized and uses the three hybrid orbitals to form three σ-bonds. The unhybridized p-orbitals on each carbon atom overlap each other and form a π-bond. As we saw in Section 3.7, although a double carbon–carbon bond is stronger than a single carbon–carbon bond, the carbon–carbon π-bond is relatively weak because the overlap responsible for the formation of the π-bond is less extensive than that responsible for the formation of the σ-bond and the enhanced electron density does not lie directly between the two nuclei. A consequence of this weakness is the reaction most characteristic of alkenes, the replacement of the π-bond by two new σ-bonds, which is discussed in Section 18.6.

Section 3.7 describes the basis for the resistance to rotation of the C=C bond.

The C=C group and all four atoms attached to it lie in the same plane and are locked into that arrangement by the resistance to twisting of the π-bond (Fig. 18.7). Because alkene molecules cannot roll up into a ball as compactly as alkanes or rotate into favorable positions, they cannot pack together as closely as alkanes; so alkenes have lower melting points than alkanes of similar molar mass.



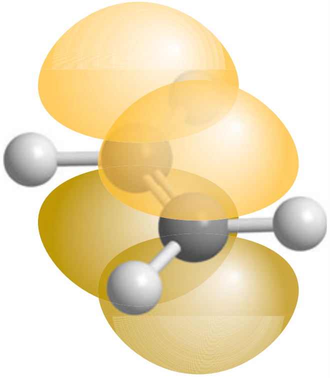


FIGURE 18.7 The π-bond (represented by the yellow electron clouds) in an alkene molecule makes the molecule resistant to twisting around a double bond. Consequently, all six atoms (the two C atoms that form the bond and the four atoms attached to them) lie in the same plane.

Animation 18.7

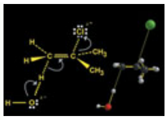
Most alkenes used in industry are produced during the refining of petroleum. One of the first refining steps is a reaction that converts some of the abundant alkanes into the more reactive alkenes:

$$CH_3CH_3(g) \xrightarrow{Cr_2O_3} CH_2{=}CH_2(g) + H_2(g)$$

This step is an example of an **elimination reaction,** a reaction in which two groups or atoms on neighboring carbon atoms are removed from a molecule, leaving a multiple bond (Fig. 18.8).

Another route commonly used in the laboratory to produce alkenes is the **dehydrohalogenation** of haloalkanes, the removal of a hydrogen atom and a halogen atom from neighboring carbon atoms:

$$CH_3CH_2CHBrCH_3 + CH_3CH_2O^- \xrightarrow{\text{ethanol at 70°C}} CH_3CH{=}CHCH_3 + CH_3CH_2OH + Br^-$$



Animation 18.8

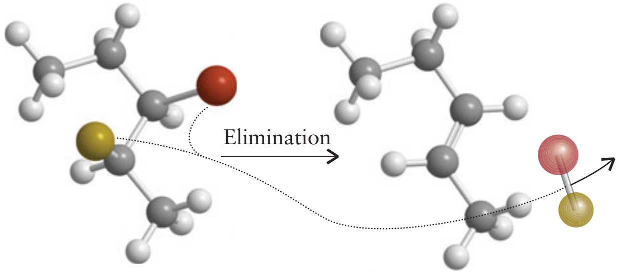


FIGURE 18.8 In an elimination reaction, two atoms or groups (the red and gold spheres) attached to neighboring carbon atoms are eliminated from the molecule, leaving a double bond between the two carbon atoms.

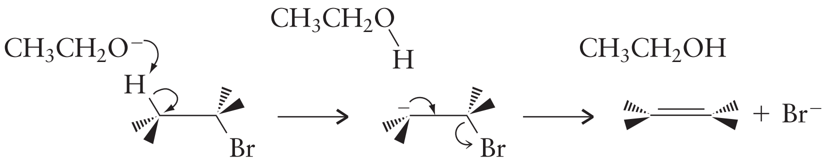
The states of reactants and products are often not given for organic reactions, because the reaction may take place at the surface of a catalyst or it may take place in a nonaqueous solvent, as here. The reaction is another example of an elimination reaction and is carried out in hot ethanol, with sodium ethoxide, $NaCH_3CH_2O$ (the ionic compound $Na^+CH_3CH_2O^-$), as the reagent. Some $CH_3CH_2CH{=}CH_2$ is also formed in this reaction.

The results of kinetic studies suggest that dehydrohalogenation occurs by the attack of the ethoxide ion ($CH_3CH_2O^-$) on a hydrogen atom attached to the carbon atom next to the carbon atom carrying the bromine atom. The ethoxide ion, acting as a very strong base, pulls an H^+ ion out of the molecule to form ethanol, $CH_3CH_2O{-}H$, leaving the carbon atom with a lone pair of electrons and a negative charge. The carbon atom uses those electrons to form a second bond to its neighbor as the bromine atom is effectively squeezed out of the molecule as a Br^- ion:



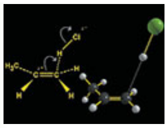
Curved arrows like the ones here are often used to illustrate organic reaction mechanisms. They show the direction in which electron pairs move as they form new bonds.

The double bonds in alkenes can be generated by elimination reactions.

18.6 Electrophilic Addition

The most characteristic chemical reaction of an alkene is an **addition reaction,** in which atoms supplied by the reactant form σ-bonds to the two atoms originally joined by the double bond (Fig. 18.9). In the process, the π-bond is lost. An example is **halogenation,** the addition of two halogen atoms at a double bond, as in the formation of 1,2-dichloroethane:

$$CH_2{=}CH_2 + Cl_2 \longrightarrow CH_2Cl{-}CH_2Cl$$



Animation 18.9

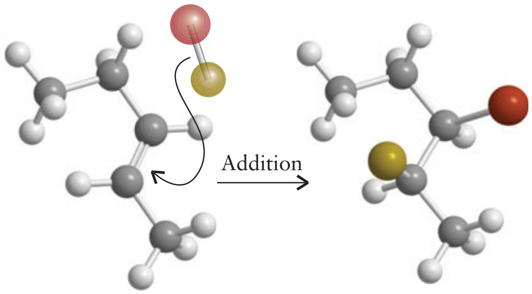


FIGURE 18.9 In an addition reaction, the atoms provided by an incoming molecule form bonds to the carbon atoms originally joined by a multiple bond.

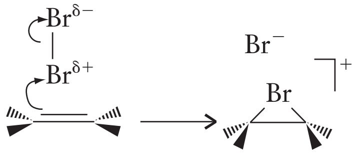
The addition of hydrogen chloride to give chloroethane is an example of a **hydrohalogenation** reaction:

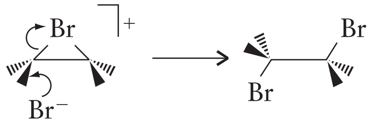
$$CH_2{=}CH_2 + HCl \longrightarrow CH_3{-}CH_2Cl$$

The model that organic chemists have built of the mechanism of alkene addition reactions is quite different from that of alkane substitution reactions. The crucial difference between the two types of molecules arises from the high density of electrons in the region of the double bond (Fig. 18.10). Because electrons are negatively charged, this region represents an accumulation of negative charge that can attract a positively charged reactant. A reactant that is attracted to a region of high electron density is called an **electrophile.** The mechanism of alkene addition is by electrophilic attack on the carbon atoms that make up the double bond. An electrophile may be a positively charged species or it may be a species that has a partial positive charge or can acquire one in the course of the reaction.

An example is the bromination of ethene. When ethene (or any other alkene) is bubbled through a solution of bromine, the solution is decolorized as the bromine reacts to form dibromoethane (this reaction is illustrated in Fig. 2.9). Bromine molecules are polarizable; and, as a Br_2 molecule approaches the high electron density of an alkene double bond, a partial positive charge is induced on the Br atom closer to the double bond (Fig. 18.11). This separation of charges means that a Br_2 molecule can act as an electrophile. As it moves in for the attack, the partially positively charged Br atom becomes more and more like Br^+, and its partner becomes more like Br^-. The bond between the two Br atoms snaps, and the Br^+ ion forms a bridge between the two carbon atoms of the alkene, giving a cyclic "bromonium ion":



Almost immediately, a Br^- ion swoops in for the attack, attracted by the positive charge of the bromonium ion. It forms a bond to one carbon atom, and the bond from that carbon atom to the bromine atom already present breaks as the bromine atom moves onto the second carbon atom, giving 1,2-dibromoethane:



With the use of a solid-state catalyst, hydrogen can be added to carbon–carbon double bonds in a **hydrogenation** reaction:

$$H_2(g) + \cdots C{=}C \cdots \xrightarrow{\text{catalyst}} \cdots CH{-}CH \cdots$$

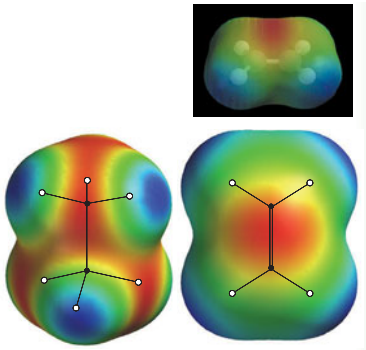
This reaction is used in the food industry to convert vegetable oils into shortening (Fig. 18.12). Oil and solid fat molecules both have long hydrocarbon chains, but oils have more double bonds. Because double bonds resist twisting, oil molecules do not pack together well, and so the oil is liquid at ordinary temperatures. When some of the double bonds are replaced by single bonds, the chains become much more flexible, and so the molecules pack together better and form a solid.

Self-Test 18.8A Write the condensed structural formula of the product of the addition of hydrogen to 2-butene: $CH_3CH{=}CHCH_3 + H_2 \longrightarrow$ product.

[***Answer:*** $CH_3CH_2CH_2CH_3$]

Self-Test 18.8B Write the condensed structural formula of the compound formed by the addition of hydrogen chloride to 2-butene.

The mechanism of addition to alkenes is electrophilic attack.



(a) (b)

FIGURE 18.10 (a) The electrostatic potential diagram for an ethane molecule: the blue regions show where the positive charge of the nuclei outweighs the negative charge of the electrons, and the red regions show where the opposite is true. (b) The electron distribution in an ethene molecule shows the negative region of charge associated with the accumulation of electrons in the region of the double bond.

Animation 18.10

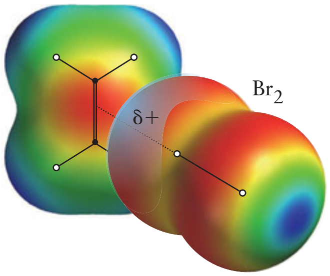


FIGURE 18.11 As a bromine molecule approaches a double bond in an alkene, the atom closer to the ethene molecule acquires a partial positive charge (the light blue region). The computation that produced this image was carried out for the point at which the bromine molecule is so close to the double bond that a carbon–bromine bond is starting to form.

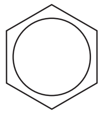
FIGURE 18.12 When the runny oil (top) is hydrogenated, it is converted into a solid fat (bottom). Hydrogen adds to the carbon–carbon double bonds, converting them into single bonds. The resulting more flexible molecules can pack together more closely and form a solid.



29 Benzene, C_6H_6

AROMATIC COMPOUNDS

Aromatic hydrocarbons, which originally got their name from the distinctive odors many of them have, are called **arenes.** They all contain an aromatic ring, usually the six-membered ring of benzene, which was introduced in Sections 2.7, 3.7, and 3.12. An abundant source of arenes is coal, which is a very complex mixture of compounds, many of which consist of extensive networks containing aromatic rings (Section 18.10).

18.7 Nomenclature of Arenes

The parent compound of aromatic hydrocarbons is benzene, C_6H_6 (**29**). When the benzene ring is named as a substituent, it is called the *phenyl* group, as in 2-phenylbutane, $CH_3CH(C_6H_5)CH_2CH_3$. In general, aromatic hydrocarbon groups are called *aryl* groups. Aromatic compounds also include the fused-ring analogs of benzene, such as naphthalene, $C_{10}H_8$ (**30**), and anthracene, $C_{14}H_{10}$ (**31**), obtained by the distillation of coal.

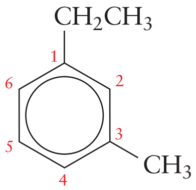
In an older but still widely used system of nomenclature, when there is a substituent in location 1 of a benzene ring, locations 2, 3, and 4 are denoted *ortho-* (abbreviated *o*-), *meta-* (*m*-), and *para-* (*p*-), respectively. Thus, (**32**) is *ortho*-dinitrobenzene. In systematic nomenclature, the locations of substituents on the aromatic ring are identified by numbering the carbon atoms from 1 to 6 around the ring, selecting the direction that corresponds to the lower substituent numbers. In this system, (**32**) is 1,2-dinitrobenzene ($—NO_2$ is the nitro group). However, (**33**) is 2,4,6-trinitrophenol because the compound C_6H_5OH is phenol, and so the carbon atom attached to the —OH group is numbered 1.

EXAMPLE 18.5 **Sample Exercise: Naming an aromatic compound**

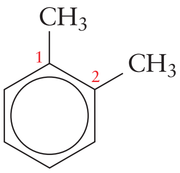
Name (a) compound (**34**) and the three dimethylbenzenes (xylenes), in which the second methyl group is on carbon atom (b) 2; (c) 3; (d) 4.

PLAN Name the compounds by counting around the ring in the direction that gives the smallest numbers to the substituents.

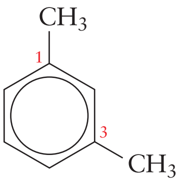
SOLVE (a) 1-Ethyl-3-methylbenzene; (b)1,2-dimethylbenzene (*o*-xylene); (c) 1,3-dimethylbenzene (*m*-xylene); (d) 1,4-dimethylbenzene (*p*-xylene)



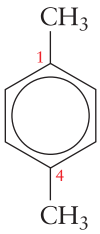
(a)



(b)



(c)



(d)

Self-Test 18.9A Name compound (**35**).

[***Answer:*** 1-Ethyl-3-propylbenzene]

Self-Test 18.9B Name compound (**36**).

Aromatic compounds are named by giving the substituents on the benzene ring the lowest numbers. When the benzene ring is itself named as a substituent, it is called a phenyl group.

18.8 Electrophilic Substitution

Arenes are unsaturated but, unlike the alkenes, they are not very reactive. Whereas alkenes commonly take part in addition reactions, arenes undergo predominantly *substitution* reactions, with the π-bonds of the ring left intact. For example, bromine immediately adds to a double bond of an alkene but reacts with benzene only in the presence of a catalyst—typically, iron(III) bromide—and it does not affect the bonding in the ring. Instead, one of the bromine atoms replaces a hydrogen atom to give bromobenzene, C_6H_5Br:

$$C_6H_6 + Br_2 \xrightarrow{FeBr_3} C_6H_5Br + HBr$$

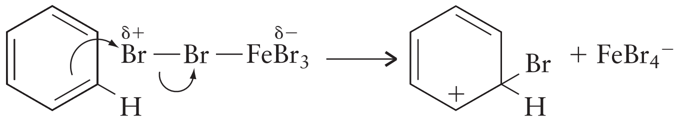
The mechanism of substitution on an electron-rich benzene ring is **electrophilic substitution,** electrophilic attack on an atom and the replacement of one atom by another or by a group of atoms. The fact that substitution occurs rather than addition to the double bonds can be traced to the stability of the delocalized π-electrons in the ring. Delocalization gives the electrons such low energy—that is, they are bound so tightly—that they are unavailable for forming new σ-bonds (see Sections 2.7 and 3.12).

The bromination of benzene illustrates the difference between electrophilic addition to alkenes and electrophilic substitution of arenes. First, to achieve the bromination of benzene it is necessary to use a catalyst, such as iron(III) bromide. The catalyst acts as a Lewis acid, binding to the bromine molecule (a Lewis base) and ensuring that the outer bromine atom has a pronounced partial positive charge:

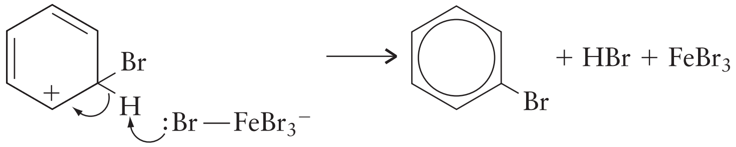
$$:Br{-}Br: + FeBr_3 \longrightarrow {}^{\delta+}:Br{-}Br{-}FeBr_3{}^{\delta-}$$

(For simplicity, we show only one lone pair on each bromine atom.) The outer bromine atom of the complex is now primed to act as a strong electrophile (Fig. 18.13).

Electrophilic substitution begins like electrophilic addition, with an attack on a region of high electron density to form a positively charged intermediate:



However, because the delocalized π-electrons constitute such a stable arrangement, the hydrogen atom shown can be pulled from the ring as H^+ by a bromine atom in the $FeBr_4{}^-$ complex. Delocalization is regained and the products are C_6H_5Br and HBr:

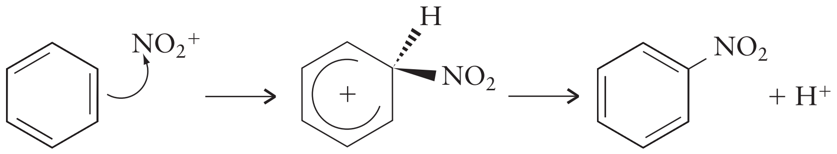


The iron(III) bromide catalyst is released in this step and is free to activate another bromine molecule.

One of the most extensively studied examples of electrophilic substitution is the nitration of benzene. A mixture of nitric acid and concentrated sulfuric acid converts benzene slowly into nitrobenzene. The actual nitrating agent is the electrophile $NO_2{}^+$ (the nitronium ion, ONO^+), a linear triatomic ion:

$$HNO_3 + H_2SO_4 \longrightarrow NO_2{}^+ + HSO_4{}^- + H_2O$$

The accepted mechanism of the reaction is



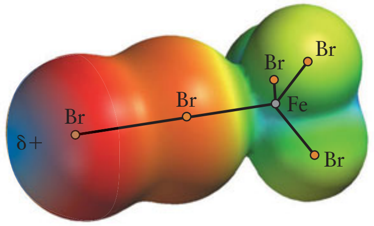


FIGURE 18.13 The catalyst $FeBr_3$ acts by forming a complex with a bromine molecule. As a result, the bromine atom not directly attached to the iron atom acquires a partial positive charge (the blue region). This partial charge enhances the ability of the bromine molecule to act as an electrophile.

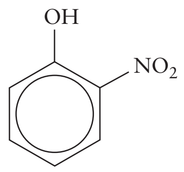
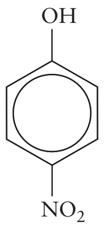


37 *o*-Nitrophenol



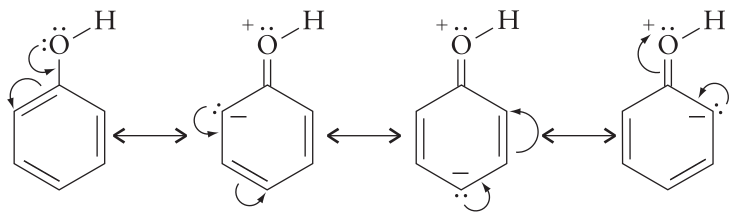
38 *p*-Nitrophenol

In the second step, the hydrogen ion is pulled out of the ring by the HSO_4^- ion acting as a Brønsted base. As in the bromination reaction, the restoration of the delocalization of the π-electrons facilitates the removal of the hydrogen ion.

Certain groups attached to an aromatic ring can donate electrons into its delocalized molecular orbitals. Examples of these electron-donating substituents include $—NH_2$ and —OH. Electrophilic substitution of benzene is much faster when an electron-donating substituent is present. For example, the nitration of phenol, C_6H_5OH, proceeds so quickly that it requires no catalyst. Moreover, when the products are analyzed, the only products are found to be 2-nitrophenol (*ortho*-nitrophenol, **37**) and 4-nitrophenol (*para*-nitrophenol, **38**).

Why is the meta position such an unattractive location for substitution, and why does phenol react much faster than benzene? An electrophile is attracted to regions of high electron density. Therefore, to account for the fast reaction of phenol, the electron density must be greater in the ring when the electron-donating —OH substituent is present. To account for the dominance of the ortho and para products, electron density must be relatively high at the ortho and para positions. A molecular orbital calculation, such as those described in Major Technique 5, shows that there is indeed a higher concentration of electrons in the ring in phenol, especially at the ortho and para positions, than in benzene, largely because the O atom has lone pairs of electrons that can participate in π-bonding with the carbon atoms (Fig. 18.14).

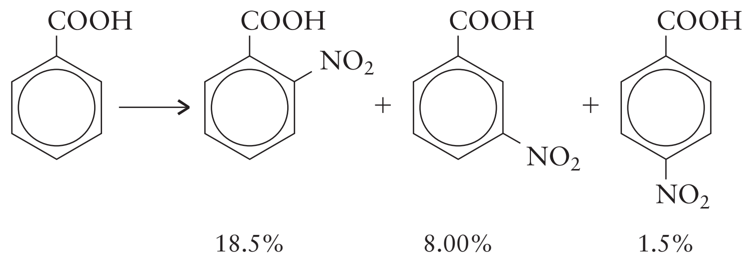
Long before their theories were supported by computations, organic chemists found a way to use resonance structures to explain the product distribution in electrophilic substitution. Thus, the Lewis structure for phenol is regarded as a resonance hybrid of the following structures:



The curved arrows show how one resonance structure relates to another. Notice that the formal negative charge is located on the ortho and para positions, exactly where reaction takes place most quickly. Other ortho- and para-directing groups include $—NH_2$, —Cl, and —Br. All have an atom with a lone pair of electrons next to the ring, and all accelerate reaction.

Thinking point: Can you suggest a molecular orbital explanation of this directing effect?

We have seen how an —OH group can accelerate a reaction. Are there substituents that can slow down the electrophilic substitution of benzene? One way to reduce the electron density in the benzene ring and to make it less attractive to electrophiles is to substitute a highly electronegative substituent, which can withdraw electrons partially, for a hydrogen atom on the benzene ring. Alternatively, we can use a substituent that removes electrons by resonance. A number of substituents, such as the carboxyl group (—COOH), have both effects. For instance, the nitration of benzoic acid, C_6H_5COOH, is found to be much slower than the nitration of benzene; moreover, most of the product is the meta nitro compound:



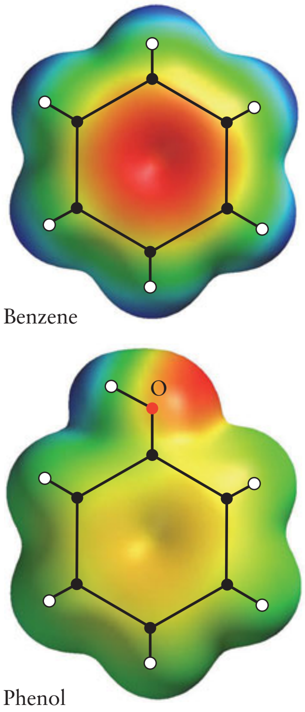


FIGURE 18.14 The presence of an –OH group in phenol alters the distribution of electrons in the benzene ring. The blue regions denote relatively positively charged parts of the molecule and the green, yellow, and red regions denote progressively more negatively charged regions. Note how the electron-rich green regions spread over the carbon and hydrogen atoms much more in phenol than in benzene; so these atoms are more susceptible to electrophilic attack. A more detailed analysis shows that the ortho and para carbon atoms have the greatest accumulation of negative charge.

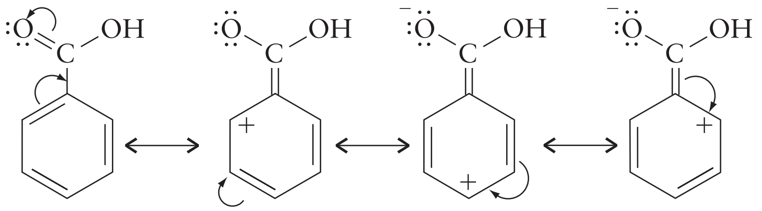
The electronegative O atoms of the carboxylic acid group withdraw electrons from the whole ring, thereby reducing its overall electron density. Moreover, resonance preferentially removes electrons from the ortho and para positions. To focus on the essentials, only the lone pairs of electrons involved in resonance are shown:



As a result of both effects, the reaction rate is lowered, especially at the ortho and para positions, and the meta position is left as the most likely place for attack. Other meta-directing electron-withdrawing substituents include —NO_2, –CF_3, and —C≡N. Notice that none of these substituents has a lone pair of electrons on the atom next to the ring.

Aromatic rings are much less reactive than their double-bond character would suggest; they commonly undergo substitution rather than addition. Electrophilic substitution of benzene with electron-donating substituents is accelerated and takes place at the ortho and para positions preferentially. Electrophilic substitution of benzene with electron-withdrawing substituents takes place at a reduced rate and primarily at the meta positions.

IMPACT ON TECHNOLOGY: FUELS

As we have seen, the primary sources of hydrocarbons are the fossil fuels petroleum and coal. Aliphatic hydrocarbons are obtained primarily from petroleum, which is a mixture of aliphatic and aromatic hydrocarbons, together with some organic compounds containing sulfur and nitrogen (Fig. 18.15). Coal is another major source of aromatic hydrocarbons.

18.9 Gasoline

The hydrocarbons in petroleum are separated by fractional distillation (Table 18.2). *Kerosene*, a fuel used in jet and diesel engines, contains a number of alkanes having formulas in the range C_{10} to C_{16}. Lubricating oils are mixtures in the range C_{17} to C_{22}. The heavier members of the series include the *paraffin waxes* and *asphalt*. However, the primary use of petroleum is for gasoline production, and the gasoline fraction (from C_5 to C_{11} hydrocarbons) is too small to meet the demand. In addition, the straight-chain alkanes make poor gasoline. Therefore, petroleum is refined to increase both the quantity and the quality of gasoline.

Fractional distillation is discussed in more detail in Section 9.19.

The quantity of gasoline that can be obtained from petroleum is increased by *cracking*, or breaking down long hydrocarbon chains, and by *alkylation*, or combining small molecules to make larger ones. In cracking, the less volatile fractions are exposed to high temperatures in the presence of a catalyst, often a modified zeolite (see Section 14.15). For example, fuel oil can be converted into a mixture of octene and octane isomers:

$$C_{16}H_{34} \xrightarrow{\Delta,\ \text{catalyst}} C_8H_{16} + C_8H_{18}$$

Alkylation also requires a catalyst to achieve the desired chain length. Octane, for instance, can be synthesized from a mixture of butane and butene:

$$C_4H_{10} + C_4H_8 \xrightarrow{\text{catalyst}} C_8H_{18}$$

TABLE 18.2 Hydrocarbon Constituents of Petroleum

Hydrocarbons	Boiling range (°C)	Fraction
C_1 to C_4	−160 to 0	natural gas and propane
C_5 to C_{11}	30 to 200	gasoline
C_{10} to C_{16}	180 to 400	kerosene, fuel oil
C_{17} to C_{22}	350 and above	lubricants
C_{23} to C_{34}	low-melting-point solids	paraffin wax
C_{35} upward	soft solids	asphalt

FIGURE 18.15 Because fossil fuel reserves are limited, they must be extracted from wherever they are found. This platform is used to extract petroleum from beneath the ocean. The natural gas accompanying it cannot easily be transported, and so it is burned off.

The quality of gasoline, which determines how smoothly it burns, is measured by the *octane rating*. For example, the straight-chain molecule octane, $CH_3(CH_2)_6CH_3$, burns so poorly that it has an octane rating of −19, but its isomer 2,2,4-trimethylpentane, which is commonly called isooctane, has an octane rating of 100. The octane rating is improved by increasing the branching of the molecules and by introducing unsaturation and rings. In *isomerization*, straight-chain hydrocarbons are converted into their branched-chain isomers. For example:

$$CH_3(CH_2)_6CH_3 \xrightarrow{AlCl_3} CH_3C(CH_3)_2CH_2CH(CH_3)CH_3$$

Aromatization is the conversion of an alkane into an arene:

$$CH_3(CH_2)_5CH_3 \xrightarrow{Al_2O_3,\ Cr_2O_3} CH_3C_6H_5 + 4\ H_2$$

The product of this reaction, toluene (methylbenzene), has an octane rating of 120.

The quality of gasoline is also improved by the addition of ethanol, which has an octane rating of 120. The use of ethanol helps to reduce the demand for petroleum. Unlike petroleum, of which there are limited reserves on Earth, ethanol is a renewable fuel that can be regenerated every year (see Box 7.2).

Petroleum consists mainly of hydrocarbons, which are separated by molar mass in fractional distillation during the refining process.

18.10 Coal

As reserves of petroleum decline worldwide, interest in making better use of coal is growing. The thought of an automobile that runs on coal is strange, but the use of gasoline substitutes derived from coal is a real possibility. Unfortunately, the increased usage of coal raises environmental concerns. Coal contains a much lower ratio of hydrogen to carbon than petroleum and is harder to purify, to work, and to transport. Although both coal and petroleum contribute to the greenhouse effect, the use of coal is potentially more damaging. When it burns, coal also releases a large amount of pollution in the form of particulate matter (primarily ash) and sulfur and nitrogen oxides. Much of the research on coal is aimed at converting it into more useful fuels.

Coal contains many aromatic rings (Fig. 18.16). Coal is the end product of the decay of swamp vegetation in *anaerobic* conditions (with a very low concentration of

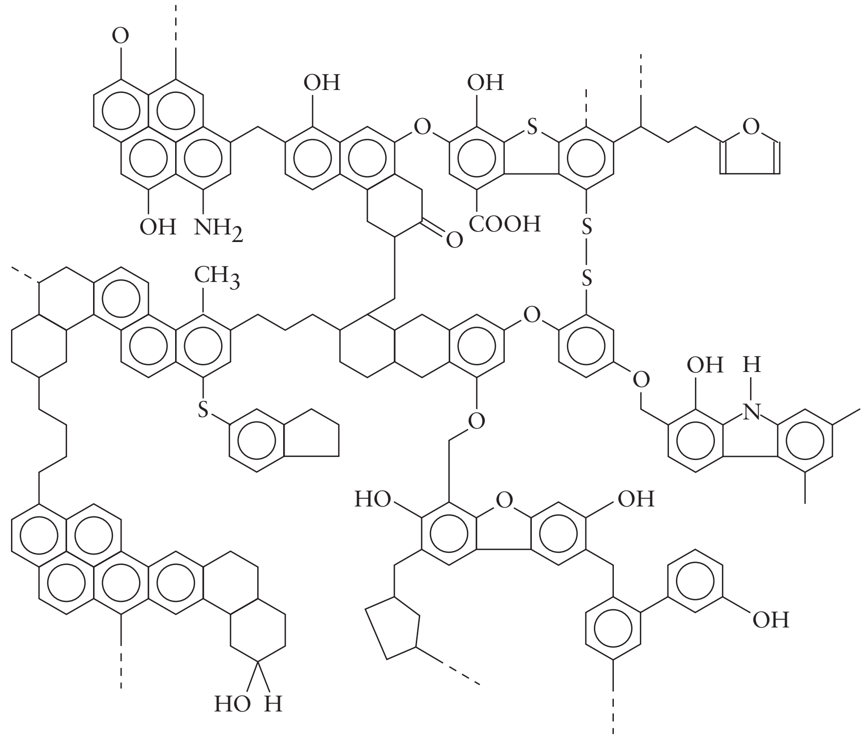


FIGURE 18.16 A highly schematic representation of a part of the structure of coal. When coal is heated in the absence of oxygen, the structure breaks up and a complex mixture of products—many of them aromatic—is obtained.

oxygen). Oxygen and hydrogen are gradually lost through the *coalification* process. As coalification proceeds, hydrogen is released and the aromatic structures increase.

When coal is destructively distilled—heated in the absence of oxygen so that it decomposes and vaporizes—its sheetlike molecules break up, and the fragments include aromatic hydrocarbons and their derivatives. *Coal gas*, which is given off first, contains carbon monoxide, hydrogen, methane, and small amounts of other gases. The complex liquid mixture that remains is called *coal tar.* A large number of pharmaceuticals, dyes, and fertilizers come from coal tar. Benzene is the raw material for many plastics, detergents, and pesticides. Naphthalene is used to make synthetic indigo (the dye in blue jeans), ammonia is used as fertilizer, and pitch, which contains the heaviest tars, is used for waterproofing and rustproofing.

Coal gas is the starting point for a number of alternative fuels. The mixture of carbon monoxide and hydrogen can be used as is, but that mixture is highly toxic. Therefore, coal gas is used to make gaseous fuels such as gaseous methane and hydrogen and liquid fuels such as methanol. These fuels are highly desired because they burn cleanly, producing little air pollution.

Coal is primarily aromatic in nature.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Distinguish alkanes, alkenes, alkynes, and arenes by differences in bonding, structure, and reactivity.

❑ 2 Name simple hydrocarbons (Toolbox 18.1 and Examples 18.1, 18.2, and 18.5).

❑ 3 Identify two molecules, given their structural formulas, as structural, geometrical, or optical isomers (Section 18.2).

❑ 4 Write the formulas of isomeric molecules (Example 18.3).

❑ 5 Judge whether a compound is chiral (Example 18.4).

❑ 6 Describe general trends in the physical properties of alkanes (Section 18.3).

❑ 7 Predict the products of given elimination, addition, and substitution reactions (Sections 18.4, 18.6, and 18.8).

❑ 8 Explain why ortho- and para-directing groups accelerate electrophilic substitution on the benzene ring and identify such groups (Section 18.8).

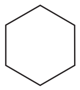
❑ 9 Describe the primary processes used in the refining of petroleum (Section 18.9).

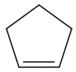
EXERCISES

Types of Hydrocarbons

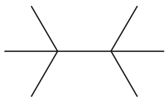
18.1 Draw Lewis structures of the following molecules and identify each as an alkane, alkene, or alkyne: (a) CH_3CCCH_3; (b) $CH_3CH_2CH_2CH_3$; (c) $CH_2CHCH_2CH_3$; (d) $CH_3CHCHCH_2CCCH_3$; (e) $CH_2CHCH_2CHCH_2$.

18.2 Give the molecular formula and identify each of the following molecules as being an alkane, alkene, or alkyne:



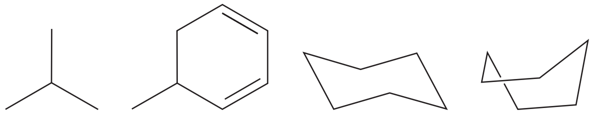


CH_2CCH_2



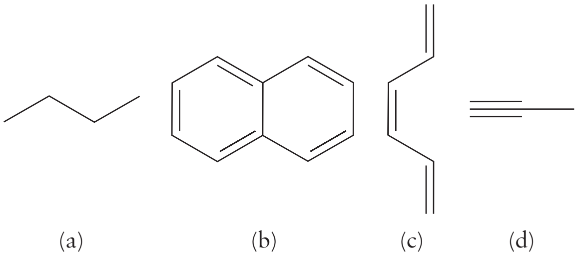
(a) (b) (c) (d)

18.3 Give the molecular formulas corresponding to the following stick figures and identify each as an alkane, an alkene, an alkyne, or an aromatic hydrocarbon



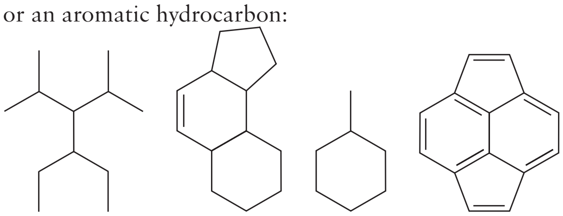
(a) (b) (c) (d)

18.4 Give the molecular formulas corresponding to the following stick figures and identify each as an alkane, an alkene, an alkyne, or an aromatic hydrocarbon:



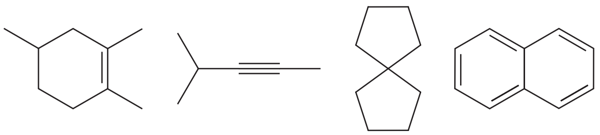
(a) (b) (c) (d)

18.5 Give the molecular formulas corresponding to the following stick figures and identify each as an alkane, an alkene, an alkyne, or an aromatic hydrocarbon:



(a) (b) (c) (d)

18.6 Give the molecular formulas corresponding to the following stick figures and identify each as an alkane, an alkene, an alkyne, or an aromatic hydrocarbon:



(a) (b) (c) (d)

Nomenclature of Hydrocarbons

18.7 Name each of the following compounds as an unbranched alkane: (a) C_3H_8; (b) C_4H_{10}; (c) C_7H_{16}; (d) $C_{10}H_{22}$.

18.8 Name each of the following compounds as an unbranched alkane: (a) C_9H_{20}; (b) C_6H_{14}; (c) $C_{11}H_{24}$; (d) $C_{12}H_{26}$.

18.9 Name the following substituents: (a) CH_3—; (b) $CH_3(CH_2)_3CH_2$—; (c) $CH_3CH_2CH_2$—; (d) $CH_3CH_2CH_2CH_2CH_2CH_2$—.

18.10 Name the following substituents: (a) $CH_3(CH_2)_8CH_2$—; (b) CH_3CH_2—; (c) $CH_3CH_2CH_2CH_2$—; (d) $CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_2$—.

18.11 Give the systematic name of (a) $CH_3CH_2CH_3$; (b) CH_3CH_3; (c) $CH_3(CH_2)_3CH_3$; (d) $(CH_3)_2CHCH(CH_3)_2$.

18.12 Give the systematic name of (a) $CH_3CH_2CH(CH_3)CH_2CH_3$; (b) $CH_3CH(CH_2CH_3)CH(CH_3)CH_3$; (c) $(CH_3)_3C(CH_2)_3CH(CH_3)_2$; (d) $CH_3C(CH_3)_2C(CH_3)_2CH_3$.

18.13 Name compound (a) $CH_3CH{=}CHCH(CH_3)_2$; (b) $CH_3CH_2CH(CH_3)C(C_6H_5)(CH_3)_2$.

18.14 Name compound (a) $CH_2{=}CHCH_2CH(C_6H_5)(CH_2)_4CH_3$; (b) $(CH_3)_2CHCH(CH_3)CHClC{\equiv}CCH_3$.

18.15 Write the shortened (condensed) structural formula of (a) 3-methyl-1-pentene; (b) 4-ethyl-3,3-dimethylheptane; (c) 5,5-dimethyl-1-hexyne; (d) 3-ethyl-2,4-dimethylpentane.

18.16 Write the shortened (condensed) structural formula of (a) 4-ethyl-2,2-dimethylhexane; (b) 3-ethyl-4-methyl-1-pentene; (c) *cis*-4-ethyl-3-heptene; (d) *trans*-4-methyl-2-hexene.

18.17 Write the structural formula of (a) 4,4-dimethylnonane; (b) 4-propyl-5,5-diethyl-1-decyne; (c) 2,2,4-trimethylpentane; (d) *trans*-3-hexene.

18.18 Write the structural formula of (a) 3,4,9-trimethyldecane; (b) 2,3,5-trimethyl-4-propylheptane; (c) 1,3-dimethylcyclohexane; (d) 5-ethyl-3-heptene.

18.19 Draw stick structures to represent each of the following molecules: (a) nonane, $CH_3(CH_2)_7CH_3$; (b) cyclopropane, C_3H_6; (c) cyclohexene, C_6H_{10}.

18.20 Draw stick structures to represent each of the following species: (a) 2,2,3,3-tetramethylhexane, $CH_3C(CH_3)_2C(CH_3)_2CH_2CH_2CH_3$; (b) the trityl cation, $(C_6H_5)_3C^+$; (c) butadiene, $CH_2CHCHCH_2$.

Isomers

18.21 Write the structural formulas for and name (a) at least 10 *alkene* isomers having the formula C_6H_{12}; (b) at least 10 *cycloalkane* isomers having the formula C_6H_{12}.

18.22 Write the structural formulas for and name all the isomers (including geometrical isomers) of the alkenes (a) C_4H_8; (b) C_5H_{10}.

18.23 Identify each of the following pairs as structural isomers, geometrical isomers, or not isomers: (a) butane and cyclobutane; (b) cyclopentane and pentene;

(c)  and 
(d)  and 
18.24 Identify each of the following pairs as structural isomers, geometrical isomers, or not isomers:
(a) 1-chlorohexane and chlorocyclohexane;

(b) and

(c) 
and 
18.25 A branched hydrocarbon C_4H_{10} reacts with chlorine in the presence of light to give two branched structural isomers with the formula C_4H_9Cl. Write the structural formulas of (a) the hydrocarbon; (b) the isomeric products.

18.26 A branched hydrocarbon C_6H_{14} reacts with chlorine in the presence of light to give only two structural isomers with the formula $C_6H_{13}Cl$. Write the structural formulas of (a) the hydrocarbon; (b) the two isomeric products.

18.27 Indicate which of the following molecules are optical isomers and identify the chiral carbon atoms in those that are: (a) $CH_3CHBrCH_2CH_3$; (b) $CH_3CH_2CHCl_2$; (c) 1-bromo-2-chloropropane; (d) 1,2-dichloropentane.

18.28 Indicate which of the following molecules are optical isomers and identify the chiral carbon atoms in those that are: (a) $CH_3CHBrCH_2Br$; (b) $CH_3CH_2CHClCH_2CH_3$; (c) 2-bromo-2-methylpropane; (d) 2,3-dimethylpentane.

Alkanes

18.29 Why do branched-chain alkanes have lower melting points and boiling points than unbranched alkanes with the same number of carbon atoms?

18.30 Arrange the following compounds in order of increasing boiling point: $CH_3CH_2CH_2CH_2CH_3$, $CH_3CH_2CH(CH_3)_2$, $C(CH_3)_4$. Explain your reasoning.

18.31 Using data available in Appendix 2A, write balanced equations and calculate the heat released when (a) 1.00 mol and (b) 1.00 g of each of the following compounds is burned in excess oxygen: propane, butane, and pentane. Is there a trend in the amount of heat released per mole of molecules or per gram of compound? If so, what is it?

18.32 Write the balanced chemical equation for the complete fluorination of methane to tetrafluoromethane. Using bond enthalpies, estimate the enthalpy of this reaction. The

corresponding reaction using chlorine is much less exothermic. To what can this difference be attributed?

18.33 How many different products containing two carbon atoms are possible in the reaction of chlorine with ethane? Do any of the products exist as optical isomers?

18.34 How many different products that retain the three-membered ring are possible in the reaction of chlorine with cyclopropane? Do any of the products exist as stereoisomers?

Alkenes

18.35 Identify the type and number of bonds on carbon atom 2 in (a) pentane; (b) 2-pentene; (c) 2-pentyne.

18.36 Predict the geometry and hybridization of the orbitals used in bonding on carbon atom 2 in (a) pentane; (b) 2-pentene; (c) 2-pentyne.

18.37 Draw the structures of *cis*-1,2-dichloropropene and *trans*-1,2-dichloropropene. Which of these molecules is polar?

18.38 Draw the structure of 1,3-pentadiene. Use valence-bond and molecular orbital pictures to describe the bonding for the σ-framework and π-orbitals, respectively.

18.39 Two structural isomers can result when hydrogen bromide reacts with 2-pentene. (a) Write their structural formulas. (b) What name is given to this type of reaction?

18.40 (a) Write a balanced equation for the production of 2,3-dibromobutane from 2-butyne. (b) What name is given to this type of reaction?

18.41 (a) Write a balanced equation for the reaction of bromocyclohexane with sodium ethoxide in ethanol. (b) Draw structural formulas of the cyclic reactant and product. (c) What name is given to this type of reaction?

18.42 Draw stick structures of the possible products for the reaction of sodium ethoxide with (a) 1-bromobutane; (b) 2-bromobutane.

18.43 Compare the reaction enthalpies for the halogenation of ethene by chlorine, bromine, and iodine. What trend, if any, exists in these numbers? Use bond enthalpies to estimate the enthalpies of reaction.

18.44 Compare the reaction enthalpies for the hydrohalogenation of ethene by HX, where X=Cl, Br, I. What trend, if any, exists in these numbers? Use bond enthalpies to estimate the enthalpies of reaction.

Aromatic Compounds

18.45 Name the following compounds:

(a) 
(b) 
18.46 Name the following compounds:

(a) 
(b) 
18.47 Write the structural formula of (a) methylbenzene, more commonly known as toluene; (b) *p*-chlorotoluene; (c) 1,3-dimethylbenzene; (d) 4-chloromethylbenzene.

18.48 Write the structural formula of (a) *p*-xylene; (b) 1,2-dibromobenzene; (c) 3-phenylpropene; (d) 2-ethyl-1,4-dimethylbenzene.

18.49 (a) Draw all the isomeric dichloromethylbenzenes. (b) Name each one and indicate which are polar and which are nonpolar.

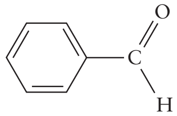
18.50 (a) Draw all the isomeric diaminodichlorobenzenes. (b) Name each one and indicate which are polar and which are nonpolar.

18.51 Draw resonance structures of cyanobenzene (C_6H_5CN) that show how it functions as a meta-directing substituent.

18.52 One can prepare bromonitrobenzenes either by nitrating bromobenzene or by brominating nitrobenzene. Will these two reactions give the same product (or product distribution)? If not, how will the products differ?

18.53 How many different compounds can be produced when naphthalene, $C_{10}H_8$ (**30**), undergoes electrophilic aromatic substitution by a single electrophile (denoted E)? Draw stick figures to represent them.

18.54 The structure of benzaldehyde is



Do you expect the aldehyde functional group (CHO) to act as a meta-directing or as an ortho, para-directing group? Explain.

Fuels

18.55 Why are hydrocarbons having between one and four carbon atoms not suitable for gasoline?

18.56 What are the major problems associated with using coal as a fuel?

18.57 Propene and butane can be combined by the process called alkylation to form a straight-chain hydrocarbon used in gasoline. Write a chemical equation for the reaction.

18.58 The compound $C_{18}H_{38}$ is a component of fuel oil that can be converted by a cracking process into two compounds suitable for use in gasoline. The compounds have the formulas C_nH_{2n+2} and C_nH_{2n}, with the value of n being the same in each. Each compound has a straight chain of carbon atoms, with no branches. Write possible structural formulas for the two compounds and name them.

Integrated Exercises

18.59 Classify each of the following reactions as addition or substitution and write its chemical equation: (a) chlorine reacts with methane when exposed to light; (b) bromine reacts with ethene in the absence of light.

18.60 Classify each of the following reactions as addition or substitution and write its chemical equation: (a) hydrogen reacts with 2-pentene in the presence of a nickel catalyst; (b) hydrogen chloride reacts with propene.

18.61 The dehydrohalogenation of haloalkanes to produce alkenes is always carried out in a nonaqueous solvent, usually ethanol. Give two reasons why water cannot be used as the solvent for the reaction.

18.62 View the animation of the alkene addition mechanism associated with Fig. 18.9 on the Web site for this book. (a) In the addition of HCl to propene an intermediate is formed. Is that intermediate positively or negatively charged? How is the charge eliminated? (b) Write a two-step mechanism for the reaction.

18.63 Propane torches are used for minor home repairs, but welders must use torches that burn acetylene (ethyne). (a) Write chemical equations for the combustion of propane and ethyne. (b) Calculate the enthalpy of combustion for each fuel per gram and per mole. (c) Use your data in part (b) to explain why welders do not use propane torches.

18.64 Consider the reaction between propene and hydrogen. (a) Calculate the equilibrium constant at 298 K. (b) Does *K* increase or decrease as the temperature is raised?

18.65 Give the systematic name of each of the following compounds. If geometrical isomers are possible, write the names of each one: (a) $CH_2{=}C(CH_3)_2$; (b) $CH_3CH{=}C(CH_3)CH_2CH_3$; (c) $HC{\equiv}CCH_2CH_2CH_2CH_3$; (d) $CH_3CH_2C{\equiv}CCH_2CH_3$; (e) $CH_3CH_2CH_2C{\equiv}CCH_3$.

18.66 Give the systematic name of each of the following compounds. If geometrical isomers are possible, write the names of each one: (a) $CH_3CH_2CH{=}CHCH_3$; (b) $CH_3C(CH_3){=}CHCH_3$; (c) $(CH_3)_2C{=}CHCH_2CH_3$; (d) $HC{\equiv}CCH_2CH(CH_2CH_2CH_3)CH_3$; (e) $CH_3CH_2C{\equiv}CCH(CH_3)CH_2CH_3$.

18.67 The structure of decalin can be found on the Web site for this book. (a) From an examination of this structure, determine the chemical formula of decalin. (b) From what aromatic hydrocarbon may decalin be produced by complete hydrogenation? (c) Are isomers possible for decalin? If so, draw the appropriate Lewis structures.

18.68 Nonsystematic names for organic compounds may still be found in the chemical literature and chemical supply catalogs, and so it is important to be somewhat familiar with these as well as with the IUPAC rules. Give the systematic name for (a) isobutane and (b) isopentane. (c) Formulate a rule for the usage of the prefix *iso-* and predict the structure of isohexane. Structures for these compounds can be found on the Web site for this book.

18.69 (a) What carbon–carbon bond angles are expected for cyclopropane? (b) What are the consequences of insisting on sp^3 hybridization for the carbon atoms in cyclopropane? (c) Calculate the enthalpy of combustion of cyclopropane using Tables 7.7 and 7.8. (d) The experimental enthalpy of combustion of cyclopropane is $-2.09\ MJ{\cdot}mol^{-1}$. Explain any difference. (*Hint*: consider how a restriction in bond angles might affect the energies of the bonds.)

18.70 Cubane is an unusual alkane in which eight carbon atoms at the corners of a cube are bonded to adjacent carbon atoms along the edges of the cube. (a) Write the chemical formula of cubane and draw its structure. (b) What carbon–carbon bond angles are expected for cubane? (c) What is the expected hybridization of the carbon atoms? (d) Some compounds based on cubane have been found to be good explosives. Write the chemical equation for the combustion of cubane and calculate its enthalpy of combustion from the bond enthalpies in Tables 7.7 and 7.8. (e) The experimental enthalpy of combustion of cubane is $-4.2\ MJ{\cdot}mol^{-1}$. Account for any difference from the calculated value and explain what makes cubane a good explosive. (*Hint*: consider how a restriction in bond angles might affect the energies of the bonds.)

18.71 In a combustion analysis, 3.21 g of a hydrocarbon formed 4.48 g of water and 9.72 g of carbon dioxide. Deduce its empirical formula and state whether it is likely to be an alkane, an alkene, or an alkyne. Explain your reasoning.

18.72 In a combustion analysis, 5.535 g of a hydrocarbon formed 6.750 g of water and 17.550 g of carbon dioxide. Deduce the empirical formula of the hydrocarbon and state whether it is likely to be an alkane, an alkene, or an alkyne. Explain your reasoning.

18.73 The following names of organic molecules are incorrect. Draw line structures and determine the correct systematic name for (a) 4-methyl-3-propylheptane; (b) 4,6-dimethyloctane; (c) 2,2-dimethyl-4-propylhexane; (d) 2,2-dimethyl-3-ethylhexane.

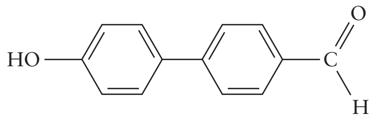
18.74 Alkanes undergo substitution of hydrogen atoms when treated with halogens. Bromination of which of the following compounds could give rise to chiral monosubstituted products: (a) ethane; (b) propane; (c) butane; (d) pentane? Include in your answer the names of the chiral compounds that would be formed.

18.75 A hydrocarbon with the formula C_3H_6 does not react with bromine in the absence of light but does react in the presence of light, producing C_3H_5Br. What is the name of this hydrocarbon?

18.76 A hydrocarbon is 90% carbon by mass and 10% hydrogen by mass and has a molar mass of $40\ g{\cdot}mol^{-1}$. It decolorizes bromine water, and 1.46 g of the hydrocarbon reacts with 1.60 L of hydrogen (measured at STP) in the presence of a nickel catalyst. Write the molecular formula of the hydrocarbon and the structural formulas of two possible isomers.

18.77 The compound 1-bromo-4-nitrobenzene (*p*-bromonitrobenzene) can be brominated. What do you expect to be the major product and why? Draw appropriate Lewis structures to support your answer.

18.78 Consider the nitration of the compound



If the reaction can be controlled so that one NO_2 group replaces one H atom of the molecule, where do you expect the nitro group to end up in the product?

18.79 (a) Draw the structure of the hydrocarbon 3,4,6-trimethyl-1-heptene. (b) Identify the chiral carbon atoms in the structure with stars. (c) Are cis and trans isomers possible for this molecule?

18.80 Trinitrotoluene, TNT, is a well-known explosive. (a) Using the structure available on the Web site, determine the systematic name for TNT. (b) TNT is made by nitrating toluene (methylbenzene) with a mixture of concentrated nitric and sulfuric acids. Explain why this particular trisubstituted isomer is the one that is formed during the nitration.

18.81 A chemist obtains the mass spectrum of 1,2-dichloro-4-ethylbenzene. Give at least four possible fragments and the masses

at which you would expect them to occur. Chlorine has two naturally occurring isotopes: ^{35}Cl, 34.969m_u, 75.53%, and ^{37}Cl, 36.966m_u, 24.47%. The mass of ^{1}H is 1.0078m_u. See Major Technique 6, Mass Spectrometry, which follows this set of exercises.

18.82 How will the mass spectrum of D_2O differ from that described in the text for H_2O? See Major Technique 6, Mass Spectrometry, which follows this set of exercises.

18.83 The occurrence of isotopes of some elements allows the presence of these elements to be readily identified in a mass spectrum of a compound. For example, Br has two naturally occurring isotopes with masses 79m_u and 81m_u, in abundances 50.5% and 49.5%, respectively. How will this information make the determination of the number of bromine atoms in an organic molecule relatively easy? For example, in the bromination of an alkane, it is possible that a number of products with more than one bromine atom might be produced. See Major Technique 6, Mass Spectrometry, which follows this set of exercises.

18.84 A chemist treats toluene (methylbenzene) with chlorine in the presence of a metal catalyst. A sample of the reaction mixture is injected into a GC-MS unit (gas chromatograph–mass spectrometer). One of the compounds that is separated by using gas chromatography gives a mass spectrum with peaks at 128m_u, 126m_u, 113m_u, 111m_u, and 91m_u, among others. The peak at 128m_u is approximately one-third the size of the peak at 126m_u, and the peak at 113m_u is approximately one-third the size of the peak at 111m_u. What is the likely composition of this compound, and what fragments may be assigned to these peaks? See Major Technique 6, Mass Spectrometry, which follows this set of exercises.

18.85 Conjugated polyenes are hydrocarbons with alternating single and double bonds. They are commonly used as dyes because they absorb in the visible range. Two such molecules have the formulas C_6H_8 and C_8H_{10}. Of the two, which has its maximum absorption at the longer wavelength? Justify your answer. See Major Technique 2, following Chapter 3.

18.86 How many liters of hydrogen at 1.00 atm and 298 K are needed to hydrogenate (a) 1.00 mol C_6H_{10}, cyclohexene; (b) 1.00 mol C_6H_6, benzene, completely? (c) Estimate the reaction enthalpy of each hydrogenation from the average bond enthalpies in Tables 7.7 and 7.8. (d) The Lewis structures imply that the enthalpy of hydrogenation of benzene is three times that of cyclohexene. Do your calculations support this implication? Explain any differences.

Chemistry Connections

18.87 A gaseous compound used to make both bubble gum and automobile tires was analyzed to determine its properties and toxicity.

(a) When 0.108 g of the compound was analyzed by combustion analysis, 0.352 g of CO_2 and 0.109 g of H_2O were produced. What is the empirical formula of the compound?
(b) The molar mass of the compound was found to be 54.09 $g\cdot mol^{-1}$. What is the molecular formula of the compound?
(c) Draw the structural formulas of at least six possible structural isomers of the compound.
(d) When the compound is exposed to hydrogen gas over a catalyst, the molar mass of the hydrogenated product is 58.12 $g\cdot mol^{-1}$. Which of the isomers in part (c) does this information help to eliminate?
(e) A 2.45-L flask was filled with the compound at 25°C and 1.0 atm. Hydrogen bromide gas was pumped into the flask until the total pressure in the flask reached 5.0 atm. Reaction then proceeded to completion because the single product was removed as fast as it was formed. After completion of the reaction the pressure of the excess HBr in the flask was 2.0 atm. What is the molecular formula of the product?
(f) The product in (e) has three structural isomers, two of which are optical isomers. Draw the structural formulas of the original compound and each of the product isomers. Place an asterisk on each chiral carbon atom.
(g) Assign a hybridization scheme to each C atom in the original compound.
(h) Write the name of the original compound.

In spectroscopy, a diffraction grating or prism is used to separate photons of light by their wavelengths. In *mass spectrometry*, a magnetic field is used to separate ions by their masses. This technique is one of our most powerful analytical methods because it provides both quantitative and qualitative information about the substance being analyzed, it requires only tiny samples, and it can be conducted in the field, by using lightweight, portable units. Mass spectrometry is used to determine isotopic abundance (Section B), to study the composition of bone and other body tissues, to analyze the blood of newborns for congenital diseases, to detect vanishingly small concentrations of drugs in urine, and to determine the structure of the human genome.

The Technique

We met a classic type of mass spectrometer in Section B. Another common type of mass spectrometer is the *large magnet mass spectrometer* (Fig. 1). In each case, the spectrometer uses the degree to which charged particles are deflected by a magnetic field to determine the relative masses of the particles. In a mass spectrometer, the sample is first vaporized and then ionized. The resulting ions are accelerated by an electric field into a narrow beam that, as it passes between a set of magnets, is deflected toward a detector. The heavier the particle, the less it is deflected, and the degree of deflection allows the relative masses of the particles to be determined. The results are displayed as a series of peaks, with the height of each peak being proportional to the relative number of particles with a given mass.

The entire spectrometer must first be evacuated (have all the air pumped out) to ensure that no gas molecules can collide with the ions produced from the sample and deflect them in unpredictable ways. Then the sample is introduced in the form of a vapor into the sample inlet chamber and through a pinhole into the ionization chamber. In this chamber, rapidly moving electrons collide violently with the molecules of the vapor. When one of the accelerated electrons collides with a molecule, the colliding electron knocks another electron out of the molecule, leaving a molecular cation. The molecular ion may split apart into two or more charged fragments. The positive ions—the original ("parent") molecular ions and their fragments—are accelerated out of the chamber by a strong electric field applied across a series of metal grids. The speeds reached by the ions depend on their masses: light ions reach higher speeds than heavier ones.

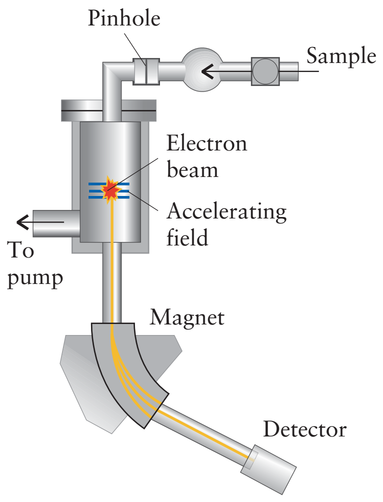


FIGURE 1 A schematic drawing of a large magnet mass spectrometer.

The rapidly moving ions pass between the poles of an electromagnet. The magnetic field bends the paths of the ions to an extent that depends on their speeds and on the strength of the field. In the large magnet mass spectrometer, the magnetic field is kept constant but the strength of the electric field is varied, and so the molecular ions are accelerated to different speeds. At a given electric field strength, ions of only one particular mass reach the detector. Any ions with different masses collide with the walls of the chamber. The strength of the electric field is varied and the result is a mass spectrum—a plot of the detector signal against the strength of the electric field. The positions of the peaks in the mass spectrum give the mass-to-charge ratios of the ions. If all the ions have charges of $+1$, then the peaks give the mass ratios and their relative heights give the proportions of ions of various masses.

Analyzing a Mass Spectrum

If the sample consists of atoms of one element, the mass spectrum gives the isotopic distribution of the sample, as in Fig. B.6. The relative molar masses of the isotopes can be determined by comparison with atoms of carbon-12. If the sample is a compound, the formula and structure of the compound can be determined by studying the fragments. For example, the $+1$ ions that CH_4 could produce are CH_4^+, CH_3^+, CH_2^+, CH^+, C^+, and H^+. Some of the particles that strike the detector are those that result when the molecule simply loses an electron (for example, to produce CH_4^+ from methane):

$$\text{Molecule} + e^- \longrightarrow \text{molecule}^+ + 2\,e^-$$

The mass of this molecular ion, the *parent ion*, is called the *parent mass*. The parent ion has essentially the same molar mass as the compound itself. However, if the electron beam is moving at a very high speed, only fragments of the molecule may survive. Some fragments are almost always produced, and other information must be used to help with the interpretation. For example, a sample of a known compound can be analyzed and its spectrum compared to that of an unknown sample to look for similar fragments. The sample can also be passed through a gas chromatograph first (see Major Technique 4). The chromatogram allows comparison with a large number of possible compounds, and the mass spectrum verifies the identification.

The identification of a molecular structure from a mass spectrum requires good chemical detective work. Let's see how that is done by trying to identify a simple compound, the one that produced the mass spectrum summarized in the table. The parent mass is 18, 19, or 20. If the parent mass is 20, the compound

Mass Spectrum of an Unknown Compound

m/e*	Peak intensity as a percentage of largest peak
1	< 0.1
16	1.0
17	21.0
18	100.0
19	0.08
20	0.22

*The quantity m/e is the conventional notation for the mass-to-charge ratio of molecular ions, with the mass a multiple of the atomic mass constant m_u and the charge a multiple of the fundamental charge e.

could be HF. However, fluorine has only one stable isotope, fluorine-19; so we could not explain the large peaks at 17 and 18. Because of the very small abundances of the peaks at 19 and 20, we can also guess that they represent the less abundant isotopes of one or more of the elements in the compound. We can conclude that the parent mass is 18 and the compound is probably water. The peaks at 19 and 20 would be due to the mass of parent molecules containing naturally occurring isotopes such as oxygen-18 and deuterium. The peak at 17 represents the OH^+ fragment, the peak at 16 would be O^+ ions, and the peak at 1 the few H^+ ions that form in the ionization process.

More complex detective work is required to analyze large biomolecules and drugs. However, fragmentation generally follows predictable patterns, and one compound can be identified by comparing its mass spectrum with those of other known compounds with similar structures. In Fig. 2, we see the spectrum of a sample of blood from a newborn infant. The blood is being analyzed to determine whether the child has phenylketonuria. The presence of the compound phenylalanine is a positive indication of the condition. Some phenylalanine labeled with a radioactive isotope has been injected along with the sample to identify the parent mass. The radioactive compound, which contains an isotope making it $5m_u$ heavier than the phenylalanine, appears in the spectrum $5m_u$ above it, thereby allowing a positive identification of the presence of the chemical.

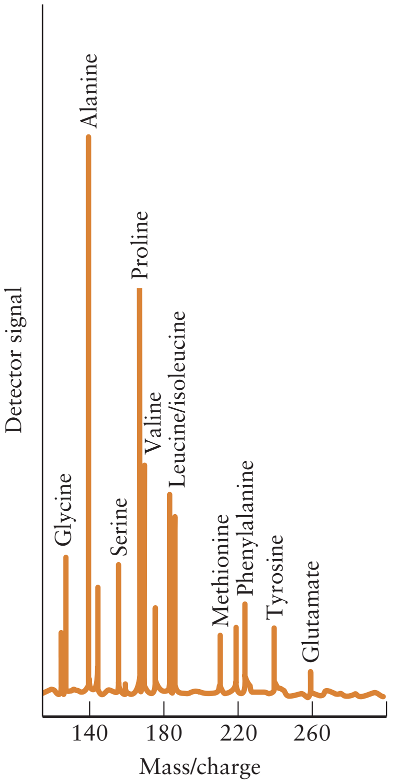

FIGURE 2 The two phenylalanine peaks include the radioactive tracer (the right-hand peak) and the phenylalanine in the blood (the peak $5m_u$ to the left). The presence of the latter peak shows that the baby from whom the blood was drawn has phenylketonuria.

19.14 Carbohydrates
19.15 Nucleic Acids

What Are the Key Ideas? The properties and reactions of many organic compounds are due to the presence of characteristic groups of atoms known as functional groups.

Why Do We Need to Know This Material? Organic chemistry is the foundation of the pharmaceutical industry and, consequently, of medicine. Organic chemistry is also the basis of biochemistry and molecular biology; through those disciplines, it provides an understanding of life. The great diversity of organic molecules found in living systems results from the presence of groups of atoms with characteristic functions. Once we understand the properties of these groups, we can predict the properties of other organic molecules, even those of the giant biomolecules of proteins, carbohydrates, and genetic material, and the synthetic polymeric materials that have revolutionized our lives.

What Do We Need to Know Already? This chapter builds on Chapter 18 and requires the same preparation, as well as the concepts of acid–base and redox reactions (Sections J and K). It also makes use of the concepts of molecular polarity (Section 3.3) and solubility (Section 9.9).

To solve some of the most difficult problems related to materials, scientists must look to organic chemistry. For example, soldiers and law enforcement officers sometimes did not wear body armor because its bulk interfered with their movement, leading to tragic loss of life. Today body armor made from organic compounds is lightweight and flexible and so is saving lives. The whole of the life-saving pharmaceutical industry is an application of organic chemistry. Molecular biology, the understanding of the processes of life, is another. This broad array of applications shows the immense variety of organic compounds, a variety that can be intimidating at first sight. Fortunately, organic compounds can be understood in terms of a relatively small number of **functional groups,** which are small groups of atoms with characteristic properties. Whereas the hydrocarbons are built only from carbon and hydrogen, functional groups may include atoms of other elements. Because functional groups have characteristic chemical properties, we do not have to learn all the properties of each different compound—once we identify the functional groups that are present, we have gone a long way toward understanding and predicting the likely chemical properties of the compound.

This chapter has three parts. In the first part, we look at the structures and properties of some of the common functional groups and describe some of the characteristic mechanisms by which the groups react. Then we examine how functional groups are used to create modern polymers. As in so many spheres, nature has preceded chemists' explorations. In the final part of the chapter, we see some examples of how functional groups in nature sustain us, feed us, and reproduce us.

COMMON FUNCTIONAL GROUPS

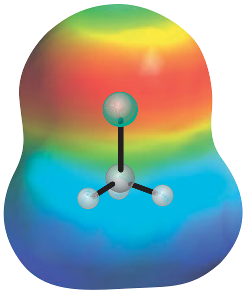
Functional groups are either attached to the carbon backbone of a molecule or form part of that chain. Examples are the chlorine atom in chloroethane, CH_3CH_2Cl, and the —OH group in ethanol, CH_3CH_2OH. Carbon–carbon multiple bonds, such as the double bond in 2-butene, $CH_3CH{=}CHCH_3$, are also often considered functional groups. Table 19.1 lists the most common functional groups. Double and triple carbon–carbon

TABLE 19.1 Common Functional Groups

Group	Class of compound	Group	Class of compound
—X	halide (X=F, Cl, Br, or I)	—COOH	carboxylic acid
—OH	alcohol, phenol	—COOR	ester
—O—	ether	—N<	amine
—CHO	aldehyde	—CO—N<	amide
—CO—	ketone		

bonds were considered in Chapter 18. In the following eight sections, we examine some other important functional groups, look at their characteristic chemical properties, and examine some of the reaction mechanisms that account for these properties.

19.1 Haloalkanes



1 Chloromethane, CH_3Cl

The **haloalkanes** (also called alkyl halides) are alkanes in which at least one hydrogen atom has been replaced by a halogen atom. Although they have important uses, many haloalkanes are highly toxic and a threat to the environment. The haloalkane 1,2-dichlorofluoroethane, $CHClFCH_2Cl$, is an example of a chlorofluorocarbon (CFC), one of the compounds held responsible for the depletion of the ozone layer (see Box 14.3). Many pesticides are aromatic compounds with several halogen atoms.

Carbon–halogen bonds are polar (**1**). The carbon atom to which the halogen atom is attached is partially positive, making it susceptible to **nucleophilic substitution,** in which a nucleophile replaces the halogen atom. A **nucleophile** is a reactant that seeks out centers of positive charge in a molecule. Two examples are the hydroxide ion, OH^-, and the water molecule, H_2O. In each case a lone pair on the oxygen atom is attracted to regions of partial positive charge; the hydroxide ion is the stronger nucleophile because of its negative charge. Water acts as a nucleophile in a hydrolysis reaction, a reaction with water in which a carbon–element bond is replaced by a carbon–oxygen bond. For example, bromomethane undergoes hydrolysis by hydroxide ions in aqueous ethanol to methanol and bromide ions:

$$CH_3Br + OH^- \longrightarrow CH_3OH + Br^-$$

Haloalkanes are alkanes in which at least one hydrogen atom has been replaced by a halogen atom; they undergo nucleophilic substitution.

19.2 Alcohols

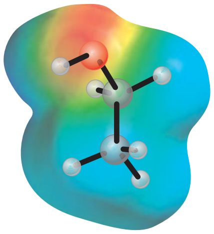


FIGURE 19.1 The charge distribution in an ethanol molecule. The red color denotes the region of net negative charge around the oxygen atom and the blue color denotes regions of net positive charge. Because the molecule is polar and can form hydrogen bonds, it is highly soluble in water.

The **hydroxyl group** is an —OH group covalently bonded to a carbon atom. An **alcohol** is an organic compound that contains a hydroxyl group not connected directly to a benzene ring or to a >C=O group. One of the best-known organic compounds is ethanol, CH_3CH_2OH, which is also called *ethyl alcohol* and *grain alcohol*. The —OH group in an alcohol molecule is polar and alcohols can give up their hydroxyl protons in certain solvents (Fig. 19.1), but their conjugate bases are so strong that they are not acids in water.

There are several ways of naming alcohols, and you need to be familiar with all three:

2-Propanol is often known by its common name, isopropyl alcohol.

- Add the suffix *-ol* to the stem of the parent hydrocarbon, as in methanol and ethanol. When the location of the —OH group needs to be specified (to avoid ambiguity), the number of the carbon atom to which it is attached is given, as in 1-propanol for $CH_3CH_2CH_2OH$ and 2-propanol for $CH_3CH(OH)CH_3$.
- Name the parent hydrocarbon as a group and attach the name alcohol, as in methyl alcohol, CH_3OH, and ethyl alcohol, CH_3CH_2OH.
- Name the —OH group as a substituent, in which case the name *hydroxy* is used, as in 2-hydroxybutane for $CH_3CH(OH)CH_2CH_3$.

We shall normally use the first of these three procedures.

Alcohols are divided into three classes according to the number of organic groups attached to the carbon atom connected to the —OH group:

Type of alcohol	Structure	Example	
primary	RCH_2—OH	ethanol, CH_3CH_2OH	secondary	R_2CH—OH	2-butanol, $CH_3CH(OH)CH_2CH_3$	tertiary	R_3C—OH	2-methyl-2-propanol, $(CH_3)_3COH$	
The common names of 2-methyl-2-propanol are tertiary-butanol and tertiary-butyl alcohol (commonly shortened to *tert*-butanol and *tert*-butyl alcohol or even *t*-butanol and *t*-butyl alcohol).

Each R represents an organic group, such as a methyl or ethyl group; they need not all be the same.

Methanol is usually prepared industrially from synthesis gas, which is obtained from coal (Section 15.3):

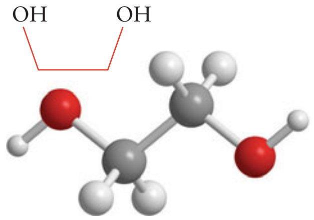
$$CO(g) + 2\,H_2(g) \xrightarrow{\text{catalyst, 250°C, 50–100 atm}} CH_3OH(g)$$

The catalyst is a mixture of copper, zinc oxide, and chromium(III) oxide. Ethanol is produced in large quantities throughout the world by the fermentation of carbohydrates. It is also prepared by the hydration of ethene in an addition reaction:

$$CH_2{=}CH_2(g) + H_2O(g) \xrightarrow{\text{catalyst, 300°C}} CH_3CH_2OH(g)$$

The catalyst is phosphoric acid. The laboratory synthesis of alcohols is by nucleophilic substitution of haloalkanes.

Ethylene glycol, or 1,2-ethanediol, $HOCH_2CH_2OH$ (**2**), is an example of a **diol,** which is a compound with two hydroxyl groups. Ethylene glycol is used as a component of antifreeze mixtures and in the manufacture of some synthetic fibers.



2 Ethanediol, $HOCH_2CH_2OH$

Alcohols with low molar masses are liquids, and alcohols have much lower vapor pressures than do hydrocarbons with approximately the same molar mass. For example, ethanol is a liquid at room temperature, but butane, which has a higher molar mass than ethanol, is a gas. The relatively low volatility of alcohols is a sign of the strength of hydrogen bonds. The ability of alcohols to form hydrogen bonds also accounts for the solubility in water of alcohols with low molar mass.

The formulas of alcohols are derived from that of water by replacing one of the hydrogen atoms with an organic group. Like water, they form intermolecular hydrogen bonds.

19.3 Ethers

An **ether** is an organic compound of the form R—O—R, where R is an alkyl group (the two R groups need not be the same). We can think of an ether as an HOH molecule in which both H atoms have been replaced by alkyl groups:

H—O—H	CH_3CH_2—O—H	CH_3CH_2—O—CH_2CH_3
Water	Ethanol (an alcohol)	Diethyl ether (an ether)

Ethers are more volatile than alcohols of the same molar mass because their molecules do not form hydrogen bonds to one another (Fig. 19.2). They are also less soluble in

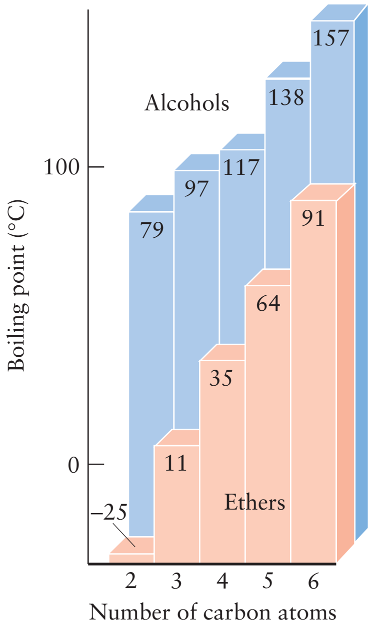


FIGURE 19.2 The boiling points of ethers are lower than those of isomeric alcohols because there is hydrogen bonding in alcohols but not in ethers. All the molecules represented here are unbranched.

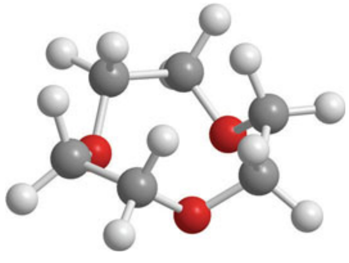
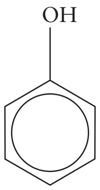


3 A crown ether

water because they can form fewer hydrogen bonds to water molecules. Because ethers are not very reactive and have low molecular polarity, they are useful solvents for other organic compounds. However, ethers are flammable; diethyl ether is easily ignited and must be used with great care.

Cyclic ethers (ethers in the form of a ring) with alternating —CH_2CH_2—O— units are called **crown ethers,** owing to the crownlike shape of the molecules (**3**). Crown ethers bind very strongly to some metal cations; for example, a crown ether effectively encases K^+ in a shell with the O atoms pointing inward toward the K^+ ion and the hydrocarbon chain wrapped around the outside. Thus, crown ether molecules act as a sort of "Trojan horse" for the K^+ ions, which in this form are soluble in nonpolar solvents. Potassium permanganate, for example, dissolves readily in benzene when a crown ether with six O atoms is added to it. The resulting solution can be used to carry out oxidation reactions in organic solvents.

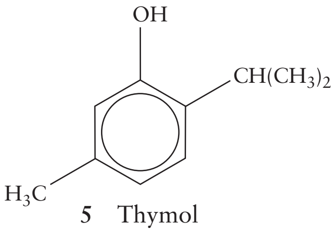
Ethers are not very reactive. They are more volatile than alcohols with similar molar masses because their molecules cannot form hydrogen bonds with one another. Crown ethers adopt shapes that can enclose ions and carry them into nonpolar solvents.



4 Phenol, C_6H_5OH

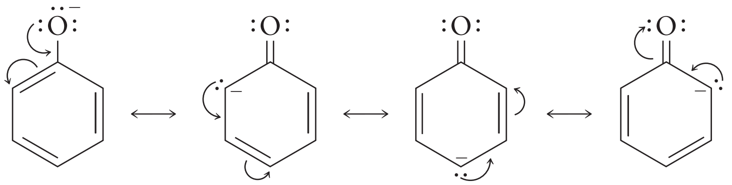
19.4 Phenols

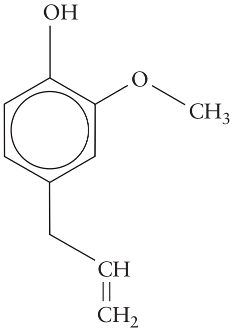
In a **phenol,** a hydroxyl group is attached directly to an aromatic ring. The parent compound, phenol itself, C_6H_5OH (**4**), is a white, crystalline, molecular solid. It was once obtained from the distillation of coal tar, but now it is mainly synthesized from benzene. Many substituted phenols occur naturally, some being responsible for the fragrances of plants. They are often components of *essential oils,* the oils that can be distilled from flowers and leaves. Thymol (**5**), for instance, is the active ingredient of oil of thyme, and eugenol (**6**) provides most of the scent and flavor of oil of cloves.



5 Thymol

Phenols differ from alcohols in that they are weak acids. Similar to the resonance in phenol itself (Section 18.8), the resonance in the anion





6 Eugenol

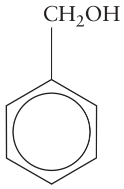
delocalizes the negative charge of the conjugate base of phenol and hence stabilizes the anion. As a result, $C_6H_5O^-$ is a weaker conjugate base than the corresponding conjugate base of an alcohol, such as $CH_3CH_2O^-$, the *ethoxide ion*, which is formed from ethanol. Consequently, phenol, C_6H_5OH, is a stronger acid than ethanol, CH_3CH_2OH, and phenols that are otherwise insoluble in water are soluble in basic solutions. However, even a single —CH_2— group can insulate the O atom from the benzene ring; and phenylmethanol, $C_6H_5CH_2OH$ (benzyl alcohol, **7**), is an alcohol, not a phenol.

Phenols are weak acids as a result of delocalization and stabilization of the conjugate base.

19.5 Aldehydes and Ketones

The **carbonyl group,** >C=O, occurs in two closely related families of compounds:

Aldehydes are compounds of the form 
Ketones are compounds of the form 

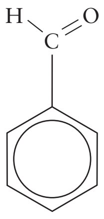


7 Benzyl alcohol, phenylmethanol, $C_6H_5CH_2OH$

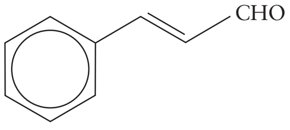
In an aldehyde, the carbonyl group is found at the end of the carbon chain, whereas in a ketone, it is at an intermediate position. The R groups may be either aliphatic or aromatic and the two R groups of a ketone need not be the same. In condensed structural formulas, the carbonyl group of a ketone is written —CO—, as in CH_3COCH_3, propanone (acetone), a common laboratory solvent. The carbonyl group in an aldehyde is normally written —CHO, as in HCHO (formaldehyde), the simplest aldehyde. *Formalin*, the liquid used to preserve biological specimens, is an aqueous solution of formaldehyde. Wood smoke contains formaldehyde, and formaldehyde's destructive effect on bacteria is one reason why smoking food helps to preserve it.

The systematic names of aldehydes are obtained by replacing the ending *-e* by *-al*, as in methanal for HCHO and ethanal for CH_3CHO. Note that the carbon atom of the carbonyl group is included in the count of carbon atoms when determining the alkane from which the aldehyde is derived. Ketones are given the suffix *-one*, as in propanone, CH_3COCH_3. To avoid ambiguity, a number is used to denote the carbon atom that has become the carbonyl group; thus, $CH_3CH_2CH_2COCH_3$ is 2-pentanone and $CH_3CH_2COCH_2CH_3$ is 3-pentanone.

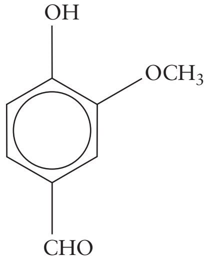
Aldehydes occur naturally in essential oils and contribute to the flavors of fruits and the odors of plants. Benzaldehyde, C_6H_5CHO (**8**), contributes to the characteristic aroma of cherries and almonds. Cinnamaldehyde (**9**) is found in cinnamon, and vanilla extract contains vanillin (**10**), which is present in oil of vanilla. Ketones can also be fragrant. For example, carvone (Section 18.1) is the essential oil of spearmint.



8 Benzaldehyde, C_6H_5CHO



9 Cinnamaldehyde



10 Vanillin

Formaldehyde is prepared industrially (for the manufacture of phenol-formaldehyde resins) by the catalytic oxidation of methanol:

$$2\,CH_3OH(g) + O_2(g) \xrightarrow{600°C,\ Ag} 2\,HCHO(g) + 2\,H_2O(g)$$

Further oxidation of the product to a carboxylic acid (Section 19.6) can be avoided by using a mild oxidizing agent. There is less risk of further oxidation for ketones than for aldehydes, because a C—C bond would have to be broken for a carboxylic acid to form.

Dichromate oxidation of secondary alcohols produces ketones in good yield, with little additional oxidation. For example, $CH_3CH_2CH(OH)CH_3$ can be oxidized to $CH_3CH_2COCH_3$. The difference between the ease of oxidation of aldehydes and that of ketones is used to distinguish them. Aldehydes can reduce silver ions to form a silver mirror—a coating of silver on test-tube walls—with *Tollens reagent*, a solution of Ag^+ ions in aqueous ammonia (Fig. 19.3):

Aldehydes: $CH_3CH_2CHO + Ag^+$ (in Tollens reagent) gives CH_3CH_2COOH and Ag(s)

Ketones: $CH_3COCH_3 + Ag^+$ (in Tollens reagent) gives no reaction

Aldehydes and ketones can be prepared by the oxidation of alcohols. Aldehydes can be more easily oxidized than ketones can.

19.6 Carboxylic Acids

The **carboxyl group,** $-C(=O)OH$, normally abbreviated —COOH, is the functional group found in **carboxylic acids,** which are weak acids of the form R—COOH. The strengths of carboxylic acids are related to their structures, as described in Section 11.10. The simplest carboxylic acid is formic acid, HCOOH, the acid in ant venom. Another common carboxylic acid is acetic acid, CH_3COOH, the acid of vinegar. It forms when the ethanol in wine is oxidized by air:

$$CH_3CH_2OH \xrightarrow{O_2} H_3C{-}C(=O)OH + H_2O$$

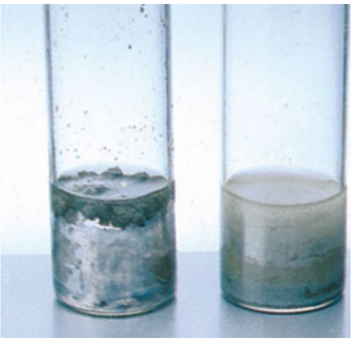


FIGURE 19.3 An aldehyde (left) produces a silver mirror with Tollens reagent, but a ketone (right) does not.

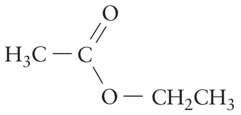
Lab Video 19.3

Carboxylic acids are named systematically by replacing the *-e* of the parent hydrocarbon by the suffix *-oic acid*; the carbon atom of the carboxyl group is included in the count of atoms to determine the parent hydrocarbon molecule. Thus, formic acid is formally methanoic acid, and acetic acid is ethanoic acid.

Carboxylic acids can be prepared by oxidizing primary alcohols and aldehydes with a strong oxidizing agent, such as acidified aqueous potassium permanganate solution. In some cases, an alkyl group can be oxidized directly to a carboxyl group. This process is very important industrially.

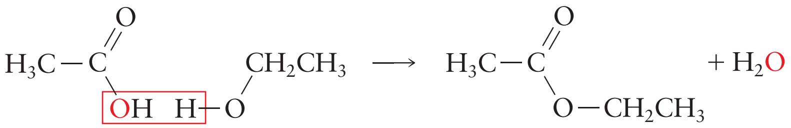
Carboxylic acids have an —OH group attached to a carbonyl group to form the carboxyl group, —COOH.



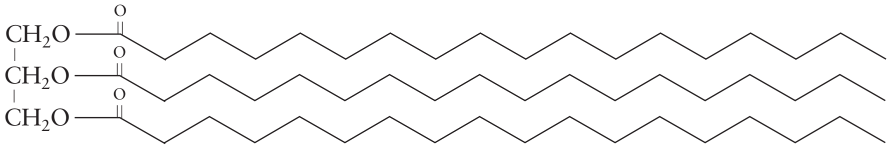
11 Ethyl acetate, $CH_3COOC_2H_5$

19.7 Esters

The product of the reaction between a carboxylic acid and an alcohol is called an **ester** (**11**). Acetic acid and ethanol, for example, react when heated to about 100°C in the presence of a strong acid. The products of this **esterification** are ethyl acetate and water:



Many esters have fragrant odors and contribute to the flavors of fruits. For example, benzyl acetate, $CH_3COOCH_2C_6H_5$, is an active component of oil of jasmine. Other naturally occurring esters include fats and oils. For example, the animal fat tristearin (**12**), which is a component of beef fat, is an ester formed from glycerol and stearic acid.



12 Tristearin, $C_{57}H_{110}O_6$

Ester formation is an example of a **condensation reaction** in which two molecules combine to form a larger one and a small molecule is eliminated (Fig. 19.4). The reaction is catalyzed by a small amount of strong acid, such as sulfuric acid. In an esterification of a carboxylic acid and an alcohol, the eliminated molecule is H_2O.

Condensation reactions provide a solution to a problem resulting from the hydrogenation of oils (Section 18.6). During the hydrogenation process the remaining double bonds are converted from their naturally occurring cis forms to the trans isomer. These fats, which are called "trans fats," can contribute to health problems such as arteriosclerosis. *Transesterification* is a technique in which enzymes are used to promote switching of the long carboxylic acid chains from one alcohol location to another in a fatty acid (see Section 9.9). The resulting fat has the desired higher melting point yet is still unsaturated and has no trans fats. The new process also reduces the need for cooling water and does not use toxic or flammable solvents.

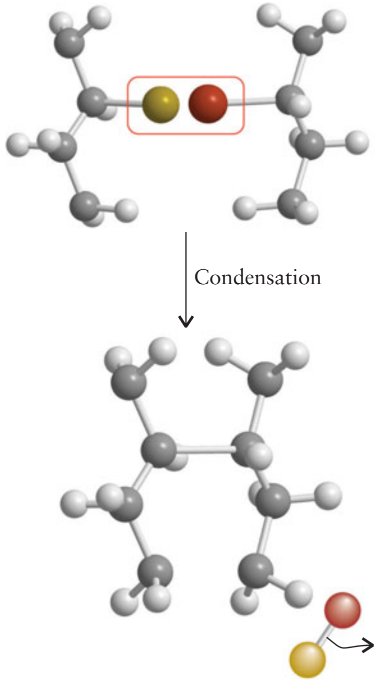


FIGURE 19.4 In a condensation reaction, two molecules are linked as a result of removing two atoms or groups (the orange and yellow spheres) as a small molecule.

Self-Test 19.1A (a) Write the condensed structural formula of the ester formed from the reaction between propanoic acid, CH_3CH_2COOH, and methanol, CH_3OH. (b) Write the condensed structural formulas of the acid and alcohol that react to form pentyl ethanoate, $CH_3COOC_5H_{11}$, a contributor to the flavor of bananas.

[***Answer:*** (a) $CH_3CH_2COOCH_3$; (b) CH_3COOH and $CH_3(CH_2)_3CH_2OH$]

Self-Test 19.1B (a) Write the condensed structural formula of the ester formed from the reaction between formic acid, HCOOH, and ethanol, CH_3CH_2OH. (b) Write the condensed structural formulas of the acid and alcohol that react to form methyl butanoate, $CH_3(CH_2)_2COOCH_3$, a contributor to the flavor of apples.

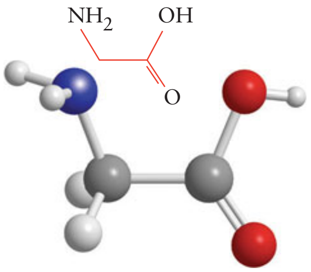
Alcohols condense with carboxylic acids to form esters.

19.8 Amines, Amino Acids, and Amides

An **amine** is a compound with a formula derived from NH_3 in which various numbers of H atoms are replaced by organic groups, which may be either aliphatic or aromatic. Amines are classified as primary, secondary, or tertiary according to the number of R groups on the nitrogen atom:

Type of amine	Structure	Example	
primary	RNH_2	methylamine, CH_3NH_2	
secondary	R_2NH	dimethylamine, $(CH_3)_2NH$	
tertiary	R_3N	trimethylamine, $(CH_3)_3N$	
Each R represents an organic group, such as a methyl or ethyl group; they need not all be the same. In each case, the N atom is sp^3 hybridized, with one lone pair of electrons and three σ-bonds. A *quaternary ammonium ion* is a tetrahedral ion of the form R_4N^+, where as many as three of the R groups (which may all be different) can be replaced by H atoms. For example, the tetramethylammonium ion, $(CH_3)_4N^+$, and the trimethylammonium ion, $(CH_3)_3NH^+$, are quaternary ammonium ions. The **amino group,** the parent functional group of amines, is $—NH_2$.

Amines are widespread in nature. Many of them have a pungent, often unpleasant odor. Because proteins are organic polymers containing nitrogen, amines are present in the decomposing remains of living matter and, together with sulfur compounds, are responsible for the stench of decaying flesh. The common names of two diamines—putrescine, $NH_2(CH_2)_4NH_2$, and cadaverine, $NH_2(CH_2)_5NH_2$—speak for themselves. Like ammonia, amines are weak bases (Section 11.7), but quaternary ammonium ions with at least one H atom attached to the N atom are generally acidic.



13 Glycine, NH_2CH_2COOH

An **amino acid** is a carboxylic acid that contains an amino group as well as a carboxyl group. The simplest example is glycine, NH_2CH_2COOH (**13**). Notice that an amino acid has both a basic group ($—NH_2$) and an acidic group ($—COOH$) in the same molecule. In aqueous solution with pH close to 7, amino acids are present as the **zwitterion,** such as $^+H_3NCH_2CO_2^-$, in which the amino group is protonated and the carboxyl group is deprotonated. There are four possible forms of an amino acid, which differ in the extent of protonation of the two functional groups. In very acidic solution, alanine exists as $^+H_3NCH(CH_3)COOH$, but, as base is added, the proton on the N is removed first, leaving $NH_2CH(CH_3)COOH$ (mainly in its zwitterion form), and then the proton from the carboxylic acid, to form $NH_2CH(CH_3)CO_2^-$. The concentrations of the various species in a solution of an amino acid can be calculated by the same methods used for polyprotic acids in Section 11.16. Figure 19.5 shows how the concentrations of alanine species present in a solution vary with pH. Notice that the molecular form of alanine is almost nonexistent at any pH: its concentration had to be multiplied by a factor of 100 million for it to be visible on the plot.

By far the most important amino acids are the α-amino acids, in which the $—NH_2$ group is attached to the carbon atom next to the carboxyl group, as in glycine. However, other types of amino acids are common and play an important biological role. For instance, the γ-amino acid $NH_2CH_2CH_2CH_2COOH$ is the neurotransmitter GABA.

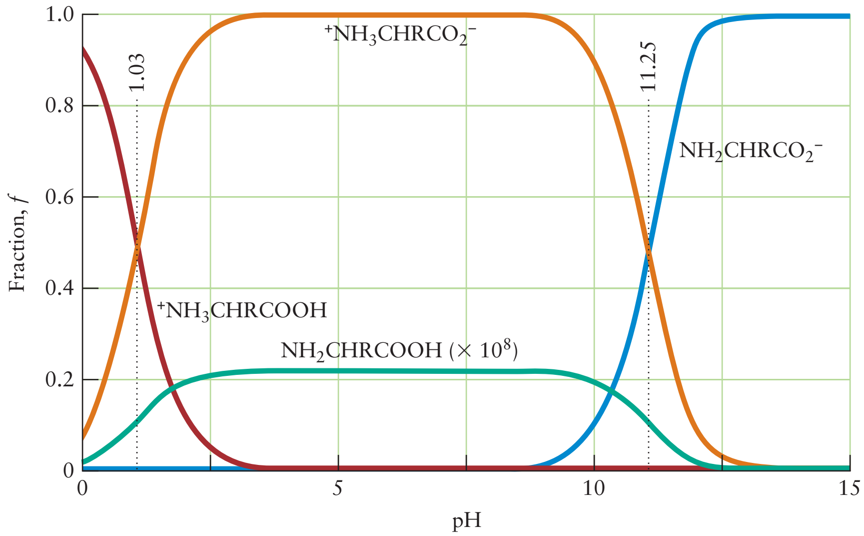


FIGURE 19.5 The fractional composition of a solution of alanine, a typical amino acid, as a function of pH. Notice that the concentration of the molecular form is extremely low at all pH values; its concentration had to be multiplied by a factor of 10^8 for it to be visible on the graph. Amino acids are present almost entirely in ionic form in aqueous solution.

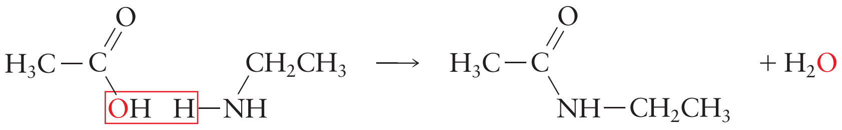
Like alcohols, amines condense with carboxylic acids:



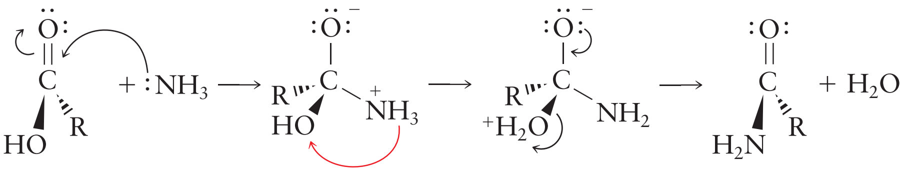
The product is an **amide.** When the reactant is a primary amine, RNH_2, the product is a molecule of the form R—(CO)—NHR.

The mechanism of amide formation is a source of insight into the properties of carboxylic acids and amines. Initially, we might expect an amine to act as a base and simply accept a proton from the carboxylic acid. Indeed, that does happen, and a quaternary ammonium salt is formed when the reagents are mixed in the absence of a solvent. For example,

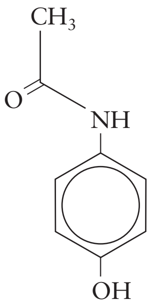
$$CH_3COOH + CH_3NH_2 \longrightarrow CH_3CO_2^- + CH_3NH_3^+$$

However, on heating to about 200°C, a thermodynamically more favorable reaction takes place. The proton transfer is reversed, and the amine acts as a nucleophile as it attacks the carbon atom of the carboxyl group in a condensation reaction:

The red arrow on the second structure shows the migration of a proton.



One example of a familiar amide is the pain-relieving drug sold as Tylenol (**14**); we shall see another important example when we consider the polymer known as nylon in Section 19.10. Many amides have N–H bonds that can take part in hydrogen bonding, and so the intermolecular forces between their molecules are relatively strong.



14 Tylenol

Self-Test 19.2A Predict whether an ester or a primary amine of the same molar mass is likely to have the higher boiling point and explain why.

[***Answer:*** The amine; it can form hydrogen bonds with the —NH_2 group, but the ester group cannot form hydrogen bonds in the pure state.]

Self-Test 19.2B What are the hybridization schemes of the C and N atoms in formamide, $HCONH_2$?

TOOLBOX 19.1 HOW TO NAME SIMPLE COMPOUNDS WITH FUNCTIONAL GROUPS

CONCEPTUAL BASIS

In general, the names of compounds containing functional groups follow the same conventions and numbering system as those used in the names of hydrocarbons (Toolbox 18.1), with the ending of the name changed to indicate the functional group. The aim here, as there, is to be succinct but unambiguous.

PROCEDURE

The functional group has priority in numbering over hydrocarbon side chains.

Alcohols

To form the systematic name, identify the parent hydrocarbon and replace the ending *-e* by *-ol*. The location of the hydroxyl group is denoted by numbering the C atoms of the backbone, starting at the end of the chain that results in the lowest number for the —OH group location. When —OH is named as a substituent, it is called *hydroxy*. For example, $CH_3CH(OH)CH_2CH_2CH_3$ is 2-pentanol or 2-hydroxypentane.

Aldehydes and ketones

For aldehydes, identify the parent hydrocarbon: include the C of —CHO in the count of carbon atoms. Then change the final *-e* of the hydrocarbon name to *-al*. The C in the —CHO group is always carbon 1, at the end of a carbon chain, and is not explicitly numbered. For ketones, change the *-e* of the parent hydrocarbon to *-one* and number the chain in the order that gives the carbonyl group the lower number. Thus, $CH_3CH_2CH_2COCH_3$ is 2-pentanone.

Carboxylic acids

Change the *-e* of the parent hydrocarbon to *-oic acid*. To identify the parent acid, include the C atom of the —COOH group when counting carbon atoms. Thus, $CH_3CH_2CH_2COOH$ is butanoic acid.

Esters

Change the *-anol* of the alcohol to *-yl* and the *-oic acid* of the parent acid to *-oate*. Thus, CH_3COOCH_3 (from meth*anol* and ethan*oic acid*) is meth*yl* ethan*oate*.

Amines

Amines are named systematically by specifying the groups attached to the nitrogen atom in alphabetical order (disregarding prefixes), followed by the suffix *-amine*. Amines with two amino groups are called *diamines*. The $—NH_2$ group is called *amino-* when it is a substituent. Thus, $(CH_3CH_2)_2CH_3N$ is diethylmethylamine and $CH_3CH(NH_2)CH_3$ is 2-aminopropane.

Halides

Name the halogen atom as a substituent by changing the *-ine* part of its name to *-o*, as in 2-chlorobutane, $CH_3CHClCH_2CH_3$.

These rules are illustrated in Example 19.1.

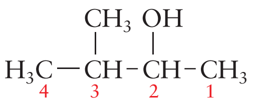
EXAMPLE 19.1 Naming compounds with functional groups

Name the compounds (a) $CH_3CH(CH_3)CH(OH)CH_3$; (b) $CH_3CHClCH_2COCH_3$; and (c) $(CH_3CH_2)_2NCH_2CH_2CH_3$.

PLAN Follow the procedures in Toolbox 19.1.

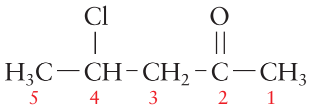
SOLVE

(a) We determine the number of carbon atoms in the longest chain and replace the ending of the name of that chain with *-ol*:



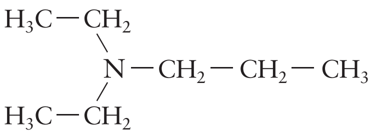
The alcohol is 3-methyl-2-butanol.

(b) The compound is both a ketone and a haloalkane. Identify the hydrocarbon chain and number the chain in the direction that gives the ketone group the lower number. The chain has five carbon atoms; the ketone group is on the second carbon atom from one end, and the chlorine atom is on the fourth:



The compound is 4-chloro-2-pentanone.

(c) The compound $(CH_3CH_2)_2NCH_2CH_2CH_3$ has two ethyl groups and one propyl group attached to a nitrogen atom. Give the ethyl groups the prefix *di-* to indicate their number and list the groups in alphabetical order.



The compound is diethylpropylamine.

Self-Test 19.3A Name (a) $CH_3CH(CH_2CH_2OH)CH_3$; (b) $CH_3CH(CHO)CH_2CH_3$; (c) $(C_6H_5)_3N$.

[***Answer:*** (a) 3-methyl-1-butanol; (b) 2-methylbutanal; (c) triphenylamine]

Self-Test 19.3B Name (a) $CH_3CH_2CH(OH)CH_2CH_3$; (b) $CH_3CH_2COCH_2CH_3$; (c) $CH_3CH_2NHCH_3$.

Amines are derived from ammonia by the replacement of hydrogen atoms with organic groups. Amides result from the condensation of amines with carboxylic acids. Amines and many amides take part in hydrogen bonding.

THE IMPACT ON TECHNOLOGY

The chains of carbon atoms in organic compounds can reach enormous lengths and give rise to *macromolecules*. **Polymers** are macromolecular compounds in which chains or networks of small repeating units form giant molecules, such as polypropylene and polytetrafluoroethylene (sold as Teflon). Polymers are made by two main types of reactions, *addition reactions* and *condensation reactions*. Which type of reaction is used depends on the functional groups present in the starting materials. Most of the raw material for polymers comes from petroleum, but some polymers are made from agricultural products such as corn and soybeans.

19.9 Addition Polymerization

Alkenes can react with themselves to form long chains in a process called **addition polymerization.** For example, an ethene molecule may form a bond to another ethene molecule; another ethene molecule may add to that, and so on, forming a long hydrocarbon chain. The original alkene, such as ethene, is a small molecule called the **monomer.** Each monomer becomes one **repeating unit,** the structure that repeats over and over to produce the polymer chain. The product, the chain of covalently linked repeating units, is the polymer. The simplest addition polymer is polyethylene, $-(CH_2CH_2)_n-$, which is made by polymerizing ethene and so consists of long chains of thousands of repeating $-CH_2CH_2-$ units. Many addition polymer molecules also have a number of branches, which are generated as new chains sprout from intermediate points along the "backbone" chain.

The plastics industry has developed polymers from a number of monomers with the formula $CHX{=}CH_2$, where X is a single atom (such as the Cl in vinyl chloride, $CHCl{=}CH_2$) or a group of atoms (such as the CH_3 in propene). These substituted ethenes are used to make polymers of formula $-(CHXCH_2)_n-$, including polyvinyl chloride (PVC), $-(CHClCH_2)_n-$, and polypropylene, $-(CH(CH_3)CH_2)_n-$ (Table 19.2). They differ in appearance, rigidity, transparency, and resistance to weathering.

TABLE 19.2 Common Addition Polymers

Monomer name	Formula	Polymer formula	Common name
ethene*	$CH_2{=}CH_2$	$-(CH_2{-}CH_2)_n-$	polyethylene
vinyl chloride	$CHCl{=}CH_2$	$-(CHCl{-}CH_2)_n-$	polyvinyl chloride
styrene	$CH(C_6H_5){=}CH_2$	$-(CH(C_6H_5){-}CH_2)_n-$	polystyrene
acrylonitrile	$CH(CN){=}CH_2$	$-(CH(CN){-}CH_2)_n-$	Orlon, Acrilan
propene*	$CH(CH_3){=}CH_2$	$-(CH(CH_3){-}CH_2)_n-$	polypropylene
methyl methacrylate	$CH_3OOCC(CH_3)C{=}CH_2$		Plexiglas, Lucite
tetrafluoroethene*	$CF_2{=}CF_2$	$-(CF_2{-}CF_2)_n-$	Teflon, PTFE†

*The suffix *-ene* is replaced by *-ylene* in the common names of these compounds, hence the names of the corresponding polymers.
†PTFE, polytetrafluoroethylene.

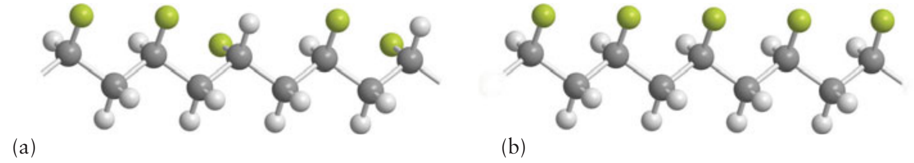


FIGURE 19.6 (a) A polymer in which the substituents lie on random sides of the chain. (b) A stereoregular polymer produced by using a Ziegler–Natta catalyst. In this case, the substituents all lie on the same side of the chain.

A widely used synthetic procedure is **radical polymerization,** polymerization by a radical chain reaction (Section 14.9). In a typical procedure, a monomer (such as ethene) is compressed to about 1000 atm and heated to 100°C in the presence of a small amount of an organic peroxide (a compound of formula R—O—O—R, where R is an organic group). The reaction is initiated by dissociation of the O—O bond, giving two radicals:

$$R{-}O{-}O{-}R \longrightarrow R{-}O\cdot + \cdot O{-}R$$

Once it has been initiated, the chain reaction can propagate as the radicals attack the monomer molecules $CHX{=}CH_2$ (with X = H for ethene itself) and form a new, highly reactive radical:

$$R{-}O\cdot + H_2C{=}C(H)(X) \longrightarrow R{-}O{-}CH_2{-}C(H)(X)\cdot$$

This radical attacks another monomer molecule, and the chain grows longer:

$$R{-}O{-}CH_2{-}C(H)(X)\cdot + H_2C{=}C(H)(X) \longrightarrow R{-}O{-}CH_2{-}C(H)(X){-}CH_2{-}C(H)(X)\cdot$$

The reaction continues until all the monomer has been used up or until it terminates when pairs of chains have linked together into single nonradical species. The product consists of macromolecules with many repeating units. Polyethylene (with X = H), for instance, consists of long chains of formula $-(CH_2CH_2)_n-$ in which n can reach many thousands.

Strong, tough polymers have chains that pack together well. One problem with early attempts to make polypropylene was that the orientations of the H and CH_3 groups on each C atom were random, thereby preventing the chains from packing well. The resulting material was amorphous, sticky, and nearly useless. Now, however, the stereochemistry of the chains can be controlled by using a **Ziegler–Natta catalyst,** a catalyst consisting of the compounds titanium tetrachloride, $TiCl_4$, and triethylaluminum, $(CH_3CH_2)_3Al$. A polymer in which each unit or pair of repeating units has the same relative orientation is described as being **stereoregular;** the stereoregularity arises from the manner in which the chains grow on the catalyst (Fig. 19.6). The chains of stereoregular polymers produced by Ziegler–Natta catalysts pack together well to form highly crystalline, dense materials (Fig. 19.7).

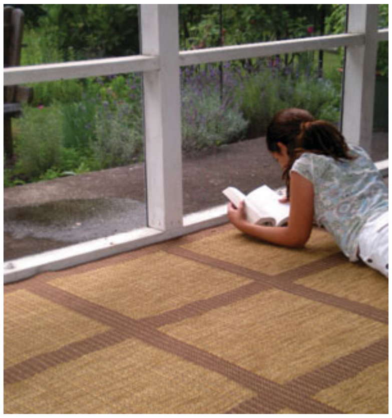

FIGURE 19.7 Polypropylene carpeting gets its strength from the regularity of the structure of its chains.

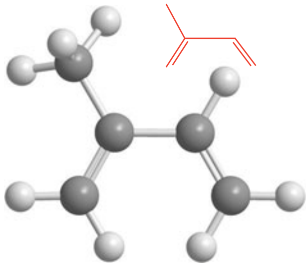
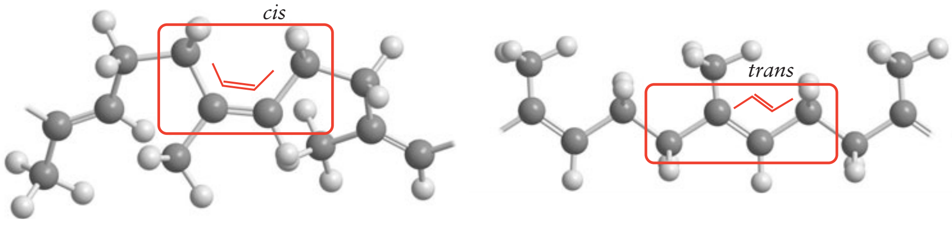
Rubber is a polymer of isoprene (**15**). Natural rubber is obtained from the bark of the rubber tree as a milky white liquid, which is called *latex* (Fig. 19.8) and consists of a suspension of rubber particles in water. The rubber itself is a soft white solid that becomes even softer when warm. It is used for pencil erasers and was once used as crepe rubber for the soles of shoes.

Chemists were unable to synthesize rubber for a long time, even though they knew it was a polymer of isoprene. The enzymes in the rubber tree produce a stereoregular polymer in which all the links between monomers are in a cis arrangement (Fig. 19.9); straightforward radical polymerization, however, produces a random mixture of cis and trans links and a sticky, useless product. The stereoregular polymer was achieved with a Ziegler–Natta catalyst, and almost pure, rubbery *cis*-polyisoprene can now be produced. *trans*-Polyisoprene, in which all the links are trans, is the hard, naturally occurring material *gutta-percha*, once used inside golf balls and still used to fill root canals in teeth.



15 Isoprene

FIGURE 19.8 Collecting latex from a rubber tree in Malaysia, a principal producer of latex.



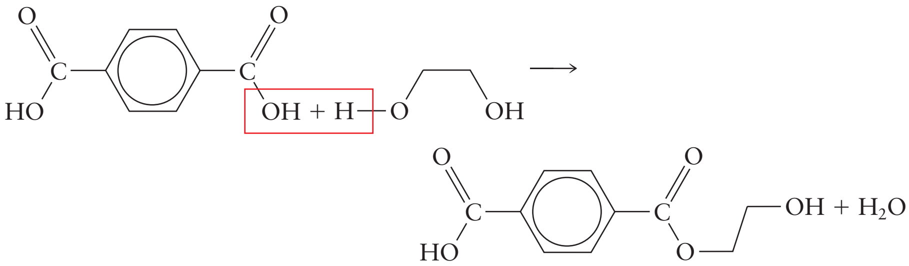
(a) (b)

FIGURE 19.9 (a) In natural rubber, the isoprene units are polymerized to be all cis. (b) The harder material, gutta-percha, is the all-trans polymer.

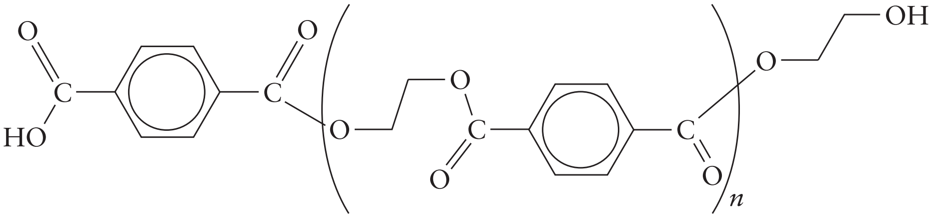
Alkenes undergo addition polymerization. When a Ziegler–Natta catalyst is used, the polymer is stereoregular and has a high density.

19.10 Condensation Polymerization

In **condensation polymers,** the monomers are linked together by condensation reactions, like those used to form ester or amide links. Polymers formed by linking together monomers that have carboxylic acid groups with those that have alcohol groups are called **polyesters.** Polymers of this type are widely used to make artificial fibers. A typical polyester is Dacron, or Terylene, a polymer produced from the esterification of terephthalic acid with ethylene glycol (see **2,** 1,2-ethanediol): its technical name is polyethylene terephthalate, or PETE. The first condensation is



A new ethylene glycol molecule can condense with the carboxyl group on one end of the product, and another terephthalic acid molecule can condense with the hydroxyl group on the other end. As a result, the polymer grows at both ends and becomes



In the radical addition polymerization of alkenes, side chains can grow out from the main chain. However, in condensation polymerization, growth can occur only at the functional groups, and so chain branching is much less likely. As a result, polyester molecules make good fibers, because the unbranched chains can be made to lie side by side when the heated product is stretched and forced through small holes (Fig. 19.10). The fibers produced can then be spun into yarn (Fig. 19.11). Polyesters can also be molded and used in surgical implants, such as artificial hearts, or made into thin films for cassette tapes.

Condensation polymerization of amines with carboxylic acids leads to the **polyamides,** substances more commonly known as *nylons*. A common polyamide is nylon-66, which is a polymer of 1,6-diaminohexane, $H_2N(CH_2)_6NH_2$, and adipic acid, $HOOC(CH_2)_4COOH$. The 66 in the name indicates the numbers of carbon atoms in the two monomers.

FIGURE 19.10 Synthetic fibers are made by extruding liquid polymer from small holes in an industrial version of a spider's spinneret.

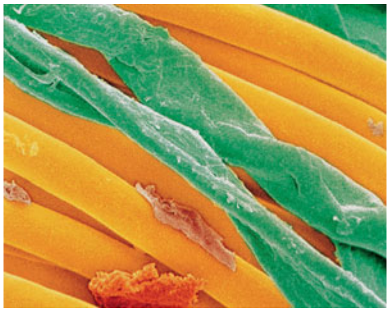


FIGURE 19.11 A scanning electron micrograph of Dacron polyester and cotton fibers in a blended shirt fabric. The cotton fibers have been colored green. Compare the smooth cylinders of polyester (orange) with the irregular surface of the cotton (green). The smooth polyester fibers resist wrinkles, and the irregular cotton fibers produce a more comfortable and absorbent texture.

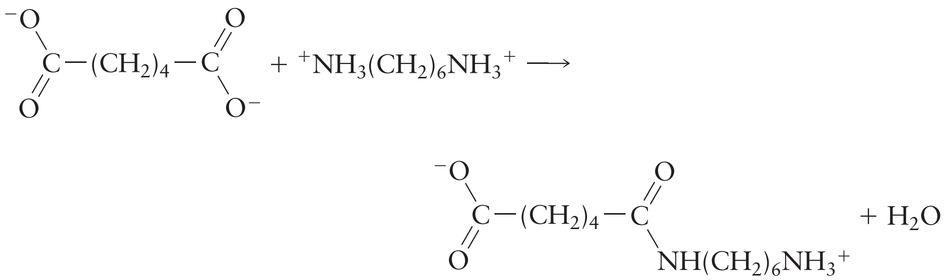
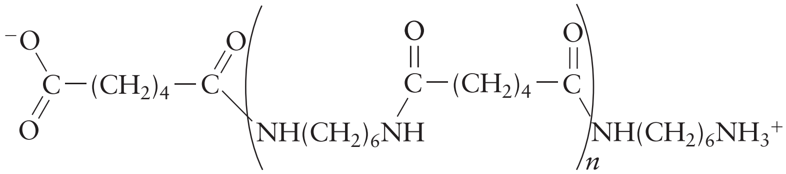
For condensation polymerization, it is necessary to have two functional groups on each monomer and to mix stoichiometric amounts of the reactants. In polyamide production, the starting materials first form "nylon salt" by proton transfer:

$$HOOC(CH_2)_4COOH + H_2N(CH_2)_6NH_2 \longrightarrow {}^{-}O_2C(CH_2)_4CO_2{}^{-} + {}^{+}H_3N(CH_2)_6NH_3{}^{+}$$

At this point, the excess acid or amine can be removed. Then, when the nylon salt is heated, the condensation begins, just as in the preparation of simple amides. The first step is



The amide grows at both ends by further condensations (Fig. 19.12), and the final product is



The long polyamide (nylon) chains can be spun into fibers (like polyesters) or molded. The N—H···O═C hydrogen bonding that takes place between neighboring chains accounts for much of the strength of nylon fibers (Fig. 19.13). This ability to form hydrogen bonds also accounts for the tendency of nylon to absorb moisture, because H_2O molecules can hydrogen bond to the polymer and worm their way in among the chains.

FIGURE 19.12 A rather crude nylon fiber can be made by dissolving the salt of an amine in water and dissolving the acid in a layer of hexane, which floats on the water. The polymer forms at the interface of the two layers, and a long string can be slowly pulled out.

Lab Video 19.12

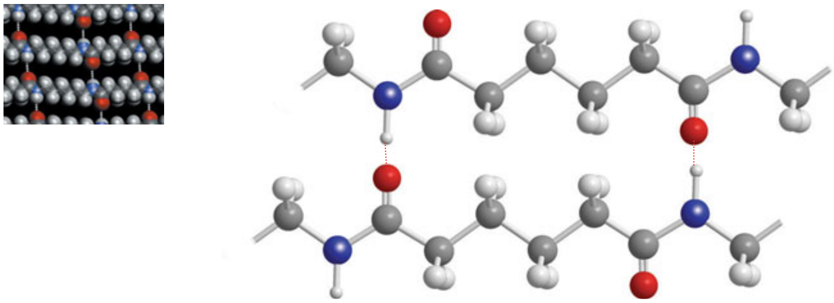


FIGURE 19.13 The strength of nylon fibers is an indication of the strength of the hydrogen bonds between neighboring polyamide chains.

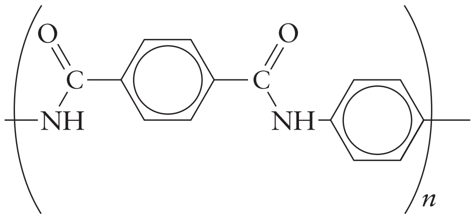
Animation 19.13

EXAMPLE 19.2 Determining the formulas of polymers and monomers

Write the formulas of (a) the monomers of Kevlar, a strong fiber used to make bulletproof vests:

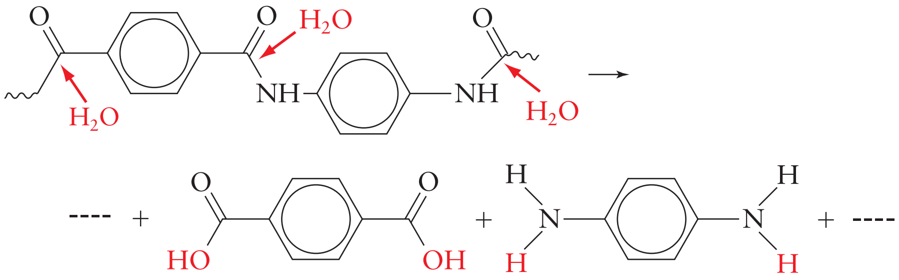


(b) two repeating units of the polymer that is formed when peroxides are added to $CH_3CH_2CH{=}CH_2$ at a high temperature and pressure.

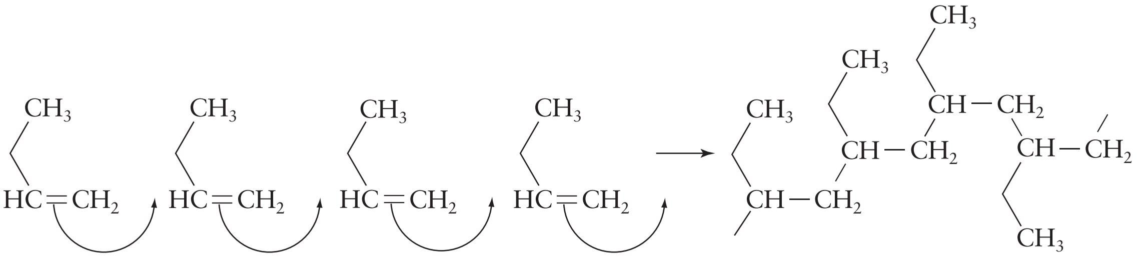
PLAN (a) Look at the backbone of the polymer, the long chain to which the other groups are attached. If the atoms are all carbon atoms, then the compound is an addition polymer. If ester groups are present in the backbone, then the polymer is a polyester and the monomers will be an acid and an alcohol. If the backbone contains amide groups, then the polymer is a polyamide and the monomers will be an acid and an amine. (b) If the monomer is an alkene or alkyne, then the monomers will add to one another; a π-bond will be replaced by new σ-bonds between the monomers. If the monomers are an acid and an alcohol or amine, then a condensation polymer forms with the loss of a molecule of water.

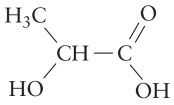
SOLVE

(a) Amide groups are present in the backbone, and so the polymer is a polyamide. Because the amide groups face in opposite directions, there are two different monomers, one with two acid groups and the other with two amine groups. We split each amide group apart and add a molecule of water to each amide link.



(b) The monomer is an alkene, so it forms an addition polymer. Replace each π-bond by an additional σ-bond to an adjacent monomer:



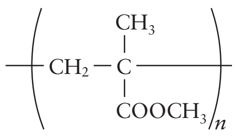


16 Lactic acid, $CH_3CH(OH)COOH$

Self-Test 19.4A (a) Write the formula for the monomer of the polymer sold as Teflon, $-(CF_2CF_2)_n-$. (b) The polymer of lactic acid (**16**) is a biodegradable polymer made from renewable resources. It is used in surgical sutures that dissolve in the body. Write the formula for a repeating unit of this polymer.

[***Answer:*** (a) $CF_2{=}CF_2$; (b) $(OCH(CH_3)CO)_n$]

Self-Test 19.4B Write the formula for (a) the monomer of poly(methyl methacrylate), used in contact lenses (**17**); (b) two repeating units of polyalanine, the polymer of the amino acid alanine, $CH_3CH(NH_2)COOH$.



17 Poly(methyl methacrylate)

Most condensation polymers are formed by the reaction of a carboxylic acid with an alcohol to form a polyester or with an amine to form a polyamide.

19.11 Copolymers

Copolymers are polymers made up of more than one type of repeating unit (Fig. 19.14). One example is nylon-66, in which the repeating units are formed from 1,6-diaminohexane, $H_2N(CH_2)_6NH_2$, and adipic acid, $HOOC(CH_2)_4COOH$. They form an **alternating copolymer,** in which acid and amine monomers alternate.

In a **block copolymer,** a long segment made from one monomer is followed by a segment formed from the other monomer. One example is the block copolymer formed from styrene and butadiene. Pure polystyrene is a transparent, brittle material that is easily broken; polybutadiene is a synthetic rubber that is very resilient, but soft and opaque. A block copolymer of the two monomers produces *high-impact polystyrene*, a material that is a durable, strong, yet transparent plastic. A different formulation of the two polymers produces *styrene–butadiene rubber* (SBR), which is used mainly for automobile tires and running shoes, but also in chewing gum.

In a **random copolymer,** different monomers are linked in no particular order. A **graft copolymer** consists of long chains of one monomer with shorter chains of the other monomer attached as side groups. For example, the polymer used to make hard contact lenses is a nonpolar hydrocarbon that repels water. The polymer used to make soft contact lenses is a graft copolymer that has a backbone of nonpolar monomers but side groups of a different water-absorbing monomer. So much water is absorbed by the side chains that 50% of the volume of the contact lens is water, which makes it pliable, soft, and more comfortable to wear than a hard contact lens. Composite materials (Section 6.21) differ from copolymers in that the two materials making up the composite retain their identities in the material and the separate regions can be large.

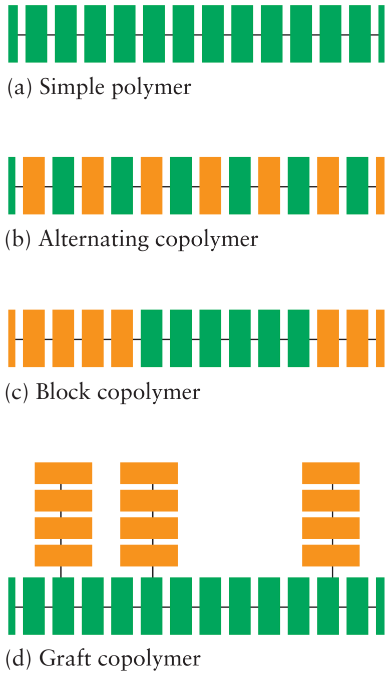


FIGURE 19.14 The classification of copolymers. (a) A simple polymer made from a single monomer represented by the green rectangles. (b) An alternating copolymer of two monomers, represented by the green and orange rectangles. (c) A block copolymer. (d) A graft copolymer.

Self-Test 19.5A Use Fig. 19.14 to identify the type of copolymer formed by monomers A and B: —AAAABBBBB—.

[***Answer:*** Block copolymer]

Self-Test 19.5B Identify the type of copolymer formed by monomers A and B: —ABABABAB—.

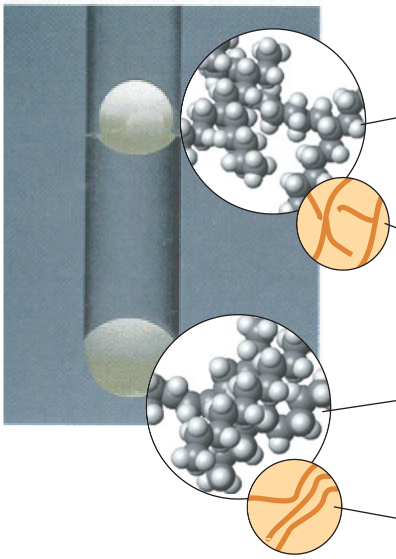
Copolymers combine the advantages of more than one component material.

19.12 Physical Properties of Polymers

A polymer can be designed to have the desired properties for an application. The first consideration is chain length. Because synthetic polymers consist of molecules with different lengths, they do not have definite molar masses. We can speak only of the *average* molar mass and the *average* chain length of a polymer. Because of the variability in chain length, polymers do not have definite melting points; rather, they soften gradually as the temperature is raised. The viscosity of a polymer, its ability to flow when molten (Section 5.7), depends on its chain length. The longer the chains, the more tangled together they may be, and hence the slower their flow.

The mechanical strength of a polymer increases as the strength of the interactions between chains increases. Therefore, the longer the chains, the greater the strength of the polymer. For chains of the same length, stronger intermolecular forces result in greater mechanical strength. The nature of the groups of atoms attached to a polymer affects the strength of intermolecular forces and contributes to the mechanical strength of the polymer. For example, nylon is a polyamide, and so has a series of repeating —NH— and —(CO)— groups that are hydrophilic and can take part in hydrogen bonding. Consequently, nylon is a strong polymer. It is also *hygroscopic* (absorbs water), because the water molecules are attracted to these polar groups. In contrast, polyethylene is a hydrocarbon that contains only

FIGURE 19.15 The two samples of polyethylene, a polymer of the hydrocarbon ethene, in the test tube were produced by different processes. The floating (low-density) one was produced by high-pressure polymerization and the chains contain many branches. The one at the bottom (high-density) was produced with a special catalyst that allowed it to pack together uniformly with a minimum of branching. As the insets show, the latter has a higher density because the polymer chains pack together better.

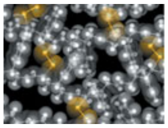


C—C and C–H bonds, which are hydrophobic. As a result, whereas polyethylene repels water, water can penetrate through thin nylon fabrics because H_2O molecules can migrate by forming and breaking hydrogen bonds to the polymer molecules.

The chain-packing arrangements that maximize intermolecular contact result in greater strength as well as greater density. Long, unbranched chains can line up next to one another like uncooked spaghetti and form crystalline regions that result in strong, dense materials. Branched polymer chains cannot fit together as closely and form weaker, less dense materials (Fig. 19.15). A soft, lightweight body armor has been developed by creating arrays of long polyethylene chains that are closely aligned in the same direction, giving rise to very strong intermolecular forces. This body armor is reported to be 15 times stronger than steel, yet has such a low density that it floats on water. It is also soft and flexible, so it is comfortable to wear (Fig. 19.16).

FIGURE 19.16 Recruits at the New York Police Academy are issued bullet-proof vests. The high-density polyethylene body armor protects law enforcement personnel without restricting movement because it is soft and flexible.

The **elasticity** of a polymer is its ability to return to its original shape after being stretched. Natural rubber has long hydrocarbon chains with low elasticity and is easily softened by heating. However, the "vulcanization" of rubber increases its elasticity. In vulcanization, rubber is heated with sulfur. The sulfur atoms form cross-links between the polyisoprene chains and produce a three-dimensional network of atoms (Fig. 19.17).



Animation 19.17

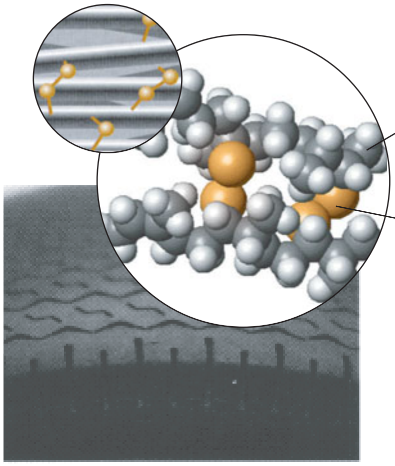


FIGURE 19.17 The gray cylinders in the small inset represent the long chains of rubber molecules, and the beaded yellow strings represent disulfide (—S—S—) links that are introduced when the rubber is vulcanized, or heated with sulfur. These cross-links increase the resilience of the rubber and make it more useful than natural rubber. Automobile tires are made of vulcanized rubber and a number of additives, including carbon.

TABLE 19.3 Recycling Codes

Recycling code	Polymer	Recycling code	Polymer
1 (1, PETE)	polyethylene terephthalate	5 (5, PP)	polypropylene
2 (2, HDPE)	high-density polyethylene	6 (6, PS)	polystyrene
3 (3, PVC)	polyvinyl chloride	7 (7, OTHER)	other
4 (4, LDPE)	low-density polyethylene		

Because the chains are covalently linked together, vulcanized rubber does not soften as much as natural rubber when the temperature is raised. Vulcanized rubber is also much more resistant to deformation when stretched, because the cross-links pull it back. Polymeric materials that return to their original shapes after stretching are called **elastomers.** However, extensive cross-linking can produce a rigid network that resists stretching. For example, high concentrations of sulfur result in very extensive cross-linking and the hard material called *ebonite*.

Plastics can be distinguished by their reaction to heat. A **thermoplastic polymer** is one that can be softened again after it has been molded; a **thermosetting polymer** is one that takes on a permanent shape in a mold and does not soften when heated. Many thermoplastic materials are made of addition polymers and can be recycled by melting and reprocessing. Examples are polyethylene and polyethylene terephthalate (Table 19.3). Thermosetting plastics are used where heat resistance is important. For example, the vulcanized rubber in vehicle tires and the urea-formaledehyde foam used to make plywood are thermosetting plastics.

Silicones are synthetic polymeric materials that are based on silicon instead of carbon. They consist of long —O—Si—O—Si— chains with the two remaining bonding positions on each Si atom occupied by organic groups, such as the methyl group, $—CH_3$ (Fig. 19.18). Silicones are used to waterproof fabrics because their oxygen atoms attach to the fabric, leaving the hydrophobic (water-repelling) methyl groups like tiny, inside-out umbrellas sticking up out of the fabric's surface. Silicone-based soft materials have a wide variety of medical and personal care uses such as implants, drug delivery, and cosmetics. They are also used in the aerospace and electronics industries as adhesives, insulators, and heat-resistant rubber.

Because they are molecular compounds, most polymers are electrical insulators. However, polymers that have alternating double bonds along the chain can be used to conduct electricity (Box 19.1). These conducting polymers tend to have long chains with few branches.

Polymers melt over a range of temperatures, and polymers consisting of long chains tend to have high viscosities. Polymer strength increases with increasing chain length and the extent of crystallization. Thermoplastic polymers are recyclable.

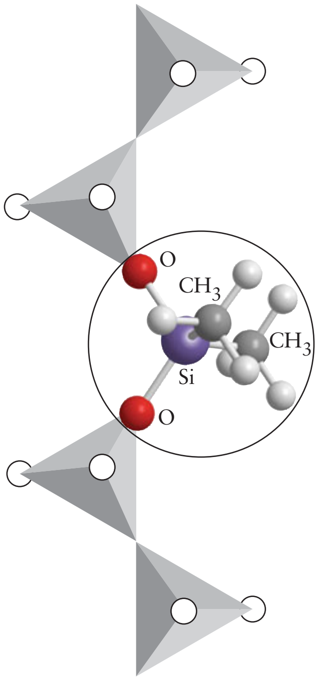

FIGURE 19.18 A typical silicone structure. The hydrocarbon groups give the substance a water-repelling quality. Note the similarity of this structure to that of the purely inorganic pyroxenes in Fig. 6.14.

THE IMPACT ON BIOLOGY

At one level, life can be regarded as a collection of hugely complex reactions taking place between organic compounds in oddly shaped containers. Many of these organic compounds are polymers, including the cellulose of wood, natural fibers such as cotton and silk, the proteins and carbohydrates in our food, and the nucleic acids of our genes.

19.13 Proteins

Protein molecules are condensation copolymers of up to twenty different naturally occurring amino acids that differ in their side chains (Table 19.4). Our bodies can synthesize eleven amino acids in sufficient amounts for our needs. But we cannot produce the proteins necessary for life unless we ingest the other nine, which are known as the **essential amino acids.**

BOX 19.1 FRONTIERS OF CHEMISTRY: CONDUCTING POLYMERS*

One day, if you want to check your e-mail in a remote location, you might unroll a plastic sheet with a tiny microprocessor embedded in it. When you activate the microprocessor, your messages will appear and you might reply by writing on the screen with a special pen or by speaking to it. The remarkable material of this flat computer already exists: one form of it was discovered by accident in the early 1970s when a chemist who was polymerizing ethyne (acetylene) added a thousand times too much catalyst. Instead of a synthetic rubber, he made a thin, flexible film. It looked like metal foil tinted pink (see the photograph), and—very much like a metal—it conducted electricity.

Metals conduct electricity because their valence electrons move easily from atom to atom. Most covalently bonded solids do not conduct electricity, because their valence electrons are locked into individual bonds and are not free to move. Exceptions such as graphite and carbon nanotubes have delocalized π-bonds in connected aromatic rings through which electrons can move freely because there are empty molecular orbitals close in energy to occupied orbitals (Sections 6.5 and 6.23). However, a disadvantage is that commercial graphite is fragile and brittle.

This flexible polyacetylene sheet was peeled from the walls of the reaction flask in which it was made.

Conducting polymers provide a new and exciting alternative. They are organic compounds that do not rust and they have low densities. They can be molded or drawn into shells, fibers, or thin plastic sheets, but they can still act like metallic conductors. They can be made to glow with almost any color and to change conductivity with conditions. Imagine cases of food labeled with polymer tags that change in conductivity when the cases are left unrefrigerated for too long.

All conducting polymers have a common feature: a long chain of sp^2 hybridized carbon atoms, often with nitrogen or sulfur atoms included in the chains. Polyacetylene, the first conducting polymer, is also the simplest, consisting of thousands of —CH=CH— units:

The alternation of double and single bonds means that each C atom has an unhybridized p-orbital that can overlap with the p-orbital on either side. This arrangement allows electrons to be delocalized along the entire chain like a one-dimensional version of graphite.

One conducting polymer, polypyrrole,

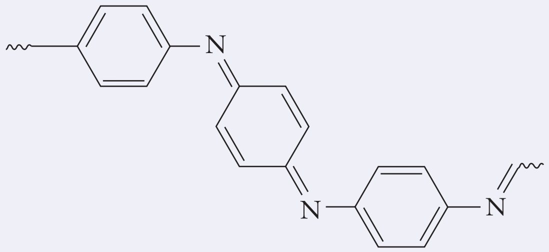
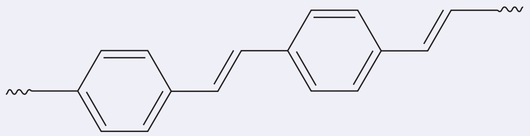
*Essential amino acids for humans.
†The entire amino acid is shown.

has been used in smart windows, which darken from a transparent yellow-green to a nearly opaque blue-black in bright sunlight. Fibers of polypyrrole are also woven into radar camouflage cloth that absorbs microwaves. Because it does not reflect microwaves back to their source, the cloth appears on radar as a patch of empty space.

Polyaniline, which has the structure



is being used in flexible coaxial cable; rechargeable, flat, buttonlike batteries; and laminated, rolled films that could be used as flexible computer or television displays. Thin films of poly-*p*-phenylenevinylene, PPV,



give off light when exposed to an electric field, a process called *electroluminescence*. By varying the composition of the polymer, scientists have coaxed it to glow in a wide range of colors. Such multicolor light-emitting diode (LED) displays can be as bright as fluorescent ones.

? HOW MIGHT YOU CONTRIBUTE?

Current PPV displays last only about 10% as long as fluorescent displays. If their longevity grows, however, they could replace the computer and television screens that we use today. Polyaniline could one day serve both as a nonmetallic solder for the printed circuit boards inside a computer and as electrical shielding for the case. All-plastic transistors and other electronic components can be miniaturized to an amazing degree, raising the possibility of nanoscale microprocessors and computers that could survive highly corrosive conditions, such as those in the body or at marine research sites. Because conducting polymers can also be designed to change shape with the level of electrical current, they could serve as artificial muscles or give flexibility of movement to robots. For these goals to be achieved, the characteristics of these polymers must be known and their responses to various conditions have to be studied.

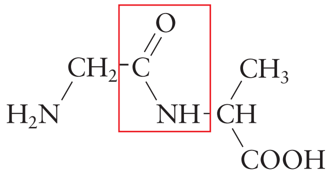
*The 2000 Nobel Prize in chemistry was awarded to A. J. Heeger, A. G. MacDiarmid, and H. Shirakawa for their discovery of conducting polymers.

A molecule formed by the condensation of two or more amino acids is called a **peptide.** An example is the combination of glycine and alanine, denoted Gly-Ala:



The —CO—NH— link shown in the red box is called a **peptide bond,** and each monomer used to form a peptide is called a **residue.** A typical protein is a polypeptide chain of more than a hundred residues joined through peptide bonds and arranged in a strict order. When only a few amino acid residues are present, we call the molecule an **oligopeptide.** The artificial sweetening agent aspartame is a type of oligopeptide called a **dipeptide** because it has two residues.

The **primary structure** of a protein is the sequence of residues in the peptide chain. Aspartame consists of phenylalanine (Phe) and aspartic acid (Asp), and so its primary structure is Phe-Asp. Three fragments of the primary structure of human hemoglobin are

Leu-Ser-Pro-Ala-Asp-Lys-Thr-Asn-Val-Lys- . . .

. . . -Val-Lys-Gly-Trp-Ala-Ala- . . .

. . . -Ser-Thr-Val-Leu-Thr-Ser-Lys-Ser-Lys-Tyr-Arg

The determination of the primary structure of a protein is a very demanding analytical task, but, thanks to automated procedures, many of these structures are now known. Any modification of the primary structure of a protein—the replacement of one amino acid residue by another—may lead to a congenital disease. Even one wrong amino acid in the chain can disrupt the normal function of the molecule (Fig. 19.19).

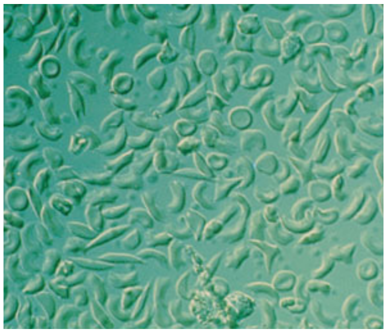


FIGURE 19.19 Sickle-shaped red blood cells form when only one amino acid (glutamic acid) in a polypeptide chain is replaced by another amino acid (valine). These cells are less able to take up oxygen than normal cells.

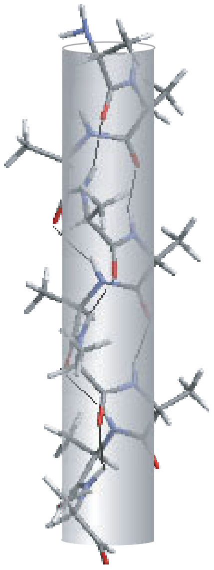

FIGURE 19.20 A representation of part of an α helix, one of the secondary structures adopted by polypeptide chains. The cylinder encloses the "backbone" of the polypeptide chain, and the side groups project outward from it. The thin lines represent the hydrogen bonds that maintain the helical shape.

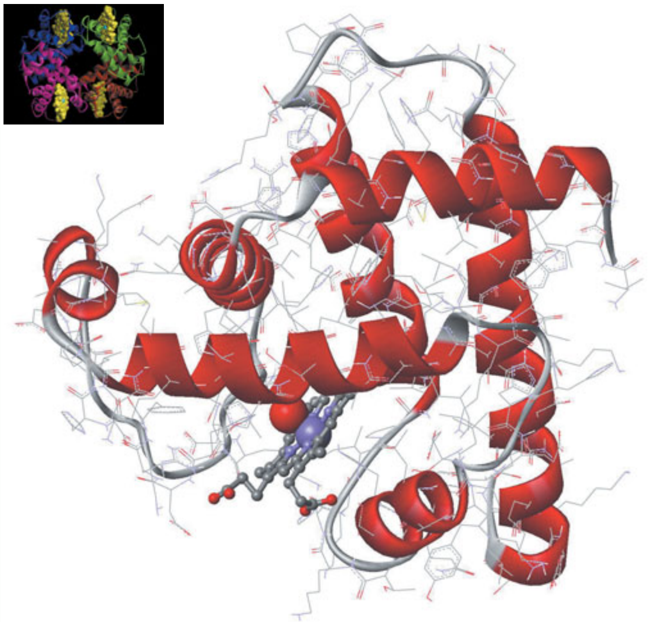
The **secondary structure** of a protein is the shape adopted by the polypeptide chain—in particular, how it coils or forms sheets. The order of the amino acids in the chain controls the secondary structure, because their intermolecular forces hold the chains together. The most common secondary structure in animal proteins is the **α helix,** a helical conformation of a polypeptide chain held in place by hydrogen bonds between residues (Fig. 19.20). One alternative secondary structure is the **β sheet,** which is characteristic of the protein that we know as silk. In silk, protein molecules lie side by side to form nearly flat sheets. The molecules of many other proteins consist of alternating α-helical and β-sheet regions (Fig. 19.21).

The **tertiary structure** of a protein is the shape into which its secondary structure is folded as a result of interactions between residues. The globular form of each chain in hemoglobin is an example. One important type of link responsible for tertiary structure is the covalent **disulfide link,** —S—S—, between residues containing sulfur. Other links are formed by the various types of intermolecular forces. In most cases, a given protein will fold into a precise three-dimensional conformation determined by the locations of the hydrophobic and hydrophilic groups on the chain (Fig. 19.22). Sometimes, however, the proteins do not fold properly. When this incorrect folding happens in the body, it can lead to illnesses such as Alzheimer's disease. In Alzheimer's disease, brain function is constricted by deposits of proteins that have misfolded and can no longer perform their functions. The so-called "prion diseases," such as variant Creutzfeld–Jakob disease ("mad cow disease"), are also due to protein misfolding. If scientists can solve the puzzle of why proteins misfold and discover how to correct that, then diseases now considered untreatable can be cured.

Proteins may also have a **quaternary structure,** in which neighboring polypeptide units stack together in a specific arrangement. The hemoglobin molecule, for example, has a quaternary structure of four polypeptide units, one of which is shown in Fig. 19.21.



Animation 19.21

FIGURE 19.21 One of the four polypeptide chains that make up the human hemoglobin molecule. The chains consist of alternating regions of α helix and β sheet. The α-helix regions are represented by red helices. The oxygen molecules that we inhale attach to the iron atom (blue sphere) and are carried through the bloodstream.

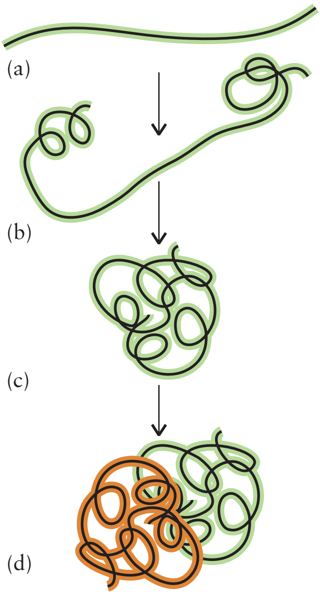


FIGURE 19.22 These structures show how a protein first forms α helices and β sheets and then how the coils and sheets fold together to form the shape of a protein. Finally, if the protein has a quaternary structure, the protein subunits stack together. (a) Newly formed polypeptide; (b) intermediate; (c) subunit; (d) mature (in this case, dimeric) protein.

FIGURE 19.23 The protein produced by spiders to make a web is a form of silk that can be exceptionally strong.

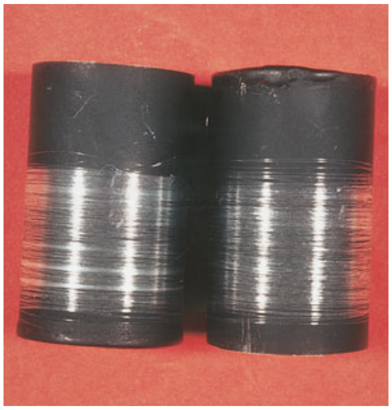

FIGURE 19.24 Artificial spider silk can now be made in bulk. It can be spun into thin, tough thread, like that on the spools shown here, or wound into cables strong enough to support suspension bridges.

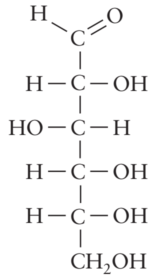
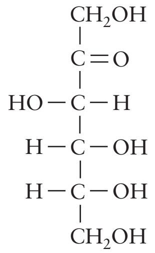
The structures of some natural protein-based materials, such as silk and wool, result in strong, tough fibers. Spiders and silkworms use proteins as a structural material of remarkable strength (Fig. 19.23). Chemists are duplicating nature by making artificial spider silk (Fig. 19.24), which is one of the strongest fibers known. Materials made of synthetic spider silk represent a great improvement over some conventional materials, because they are lightweight, thin, and flexible. For example, products as diverse as parachutes, artificial ligaments, automobile bumpers, and banknotes have been proposed for synthetic spider silk.

The loss of structure by a protein is called **denaturation.** This structural change may be a loss of quaternary, tertiary, or secondary structure; it may also be degradation of the primary structure by cleavage of the peptide bonds. Even mild heating can cause irreversible denaturation. When we cook an egg, the protein called albumen denatures into a white mass. The "permanent waving" of hair, which consists primarily of long α helices of the protein keratin, is a result of partial denaturation.

Proteins are polymers made of amino acid units. The primary structure of a polypeptide is the sequence of amino acid residues; secondary structure is the formation of helices and sheets; tertiary structure is the folding into a compact unit; quaternary structure is the packing of individual protein units together.



18 Glucose, $C_6H_{12}O_6$



19 Fructose, $C_6H_{12}O_6$

19.14 Carbohydrates

The **carbohydrates** are so called because many have the empirical formula CH_2O, which suggests a hydrate of carbon. They include starches, cellulose, and sugars such as glucose, $C_6H_{12}O_6$ (**18**), which contains an aldehyde group, and fructose (fruit sugar), a structural isomer of glucose that is a ketone (**19**). Carbohydrates have many —OH groups, and so they may also be regarded as alcohols. The presence of these —OH groups allows them to form numerous hydrogen bonds with one another and with water.

The **polysaccharides** are polymers of glucose. They include starch, which we can digest, and cellulose, which we cannot. Starch is made up of two components: amylose and amylopectin. Amylose, which makes up about 20% to 25% of most starches, consists of chains made up of several thousand glucose units linked together (Fig. 19.25).

FIGURE 19.25 The amylose molecule, one component of starch, is a polysaccharide, a polymer of glucose. It consists of glucose units linked together to give a structure like the one shown but with a moderate degree of branching.

Animation 19.25

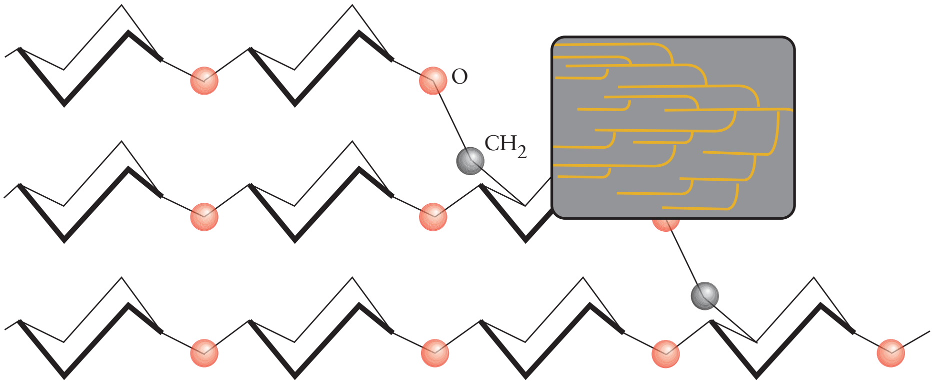


FIGURE 19.26 The amylopectin molecule is another component of starch. It has a more highly branched structure than amylose, as emphasized in the inset.

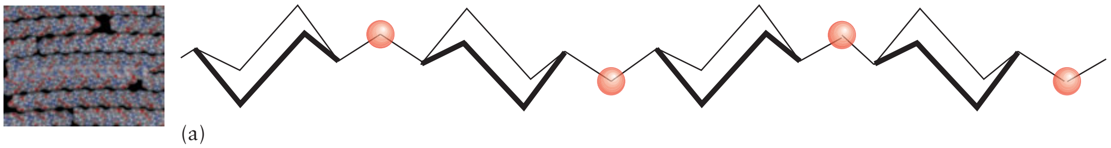
Amylopectin is also made up of glucose chains (Fig. 19.26), but its chains are linked into a branched structure and its molecules are much larger. Each molecule consists of about a million glucose units.

Cellulose is the structural material of plants. It is a polymer with the same monomer (glucose) that starch has, but the units in cellulose are linked differently, forming flat, ribbonlike strands (Fig. 19.27). Hydrogen bonds between these strands lock them together into a rigid structure that for us (but not for termites) is indigestible. Cellulose is the most abundant organic chemical in the world, and billions of tons of it are produced annually by photosynthesis. In research on alternative fuels, enzymes are used to break down the cellulose in waste biomass into glucose, which is then fermented to make ethanol for use as a fuel (see Box 7.2).

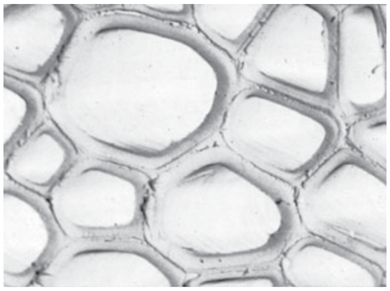
Carbohydrates include sugars, starches, and cellulose. Glucose is an alcohol and an aldehyde that polymerizes to form starch and cellulose.

19.15 Nucleic Acids

The nucleus of every living cell contains at least one deoxyribonucleic acid (DNA) molecule to control the production of proteins and to carry genetic information from one generation of cells to the next. Human DNA molecules are immense: if a molecule of DNA could be extracted without damage from a cell nucleus and drawn out straight from its highly coiled natural shape, it would be about 2 m long (Fig. 19.28). The ribonucleic acid (RNA) molecule is closely related to DNA. One of its functions is to carry information stored by DNA to a region of the cell where that information can be used in protein synthesis.



(a)



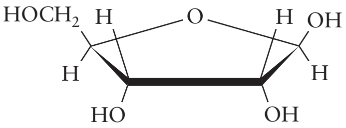
(b)

FIGURE 19.27 (a) Cellulose is yet another polysaccharide constructed from glucose units. The units in cellulose link together in such a way that they form long, flat ribbons that can produce a fibrous material through hydrogen bonding. (b) These long tubes of cellulose (shown in cross section) form the structural material of an aspen tree.

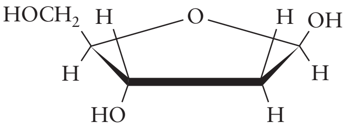
Animation 19.27

FIGURE 19.28 A DNA molecule is very large, even in bacteria. In this micrograph, a DNA molecule has spilled out through the damaged cell wall of a bacterium.

DNA is a polymer with a backbone built of repeating units derived from the sugar ribose (**20**). For DNA, the ribose molecule has been modified by removing the oxygen atom at carbon atom 2, the second carbon atom clockwise from the ether oxygen atom in the five-membered ring. Therefore, the repeating unit—the monomer—is called deoxyribose (**21**).

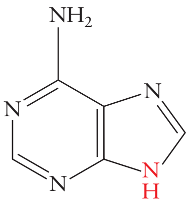


20 Ribose, $C_5H_{10}O_5$

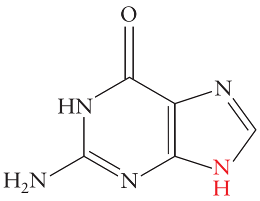


21 Deoxyribose, $C_5H_{10}O_4$

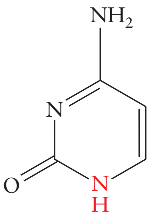
Attached by a covalent bond to carbon atom 1 of the deoxyribose ring is an amine (and therefore a base), which may be adenine, A (**22**); guanine, G (**23**); cytosine, C (**24**); or thymine, T (**25**). In RNA, uracil, U (**26**), replaces thymine. The base bonds to carbon atom 1 of deoxyribose through the nitrogen of the —NH— group (printed in red); and the compound so formed is called a **nucleoside.** All nucleosides have a similar structure, which we can summarize as the shape shown in (**27**); the lens-shaped object represents the attached amine.



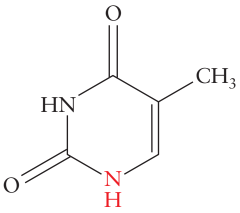
22 Adenine



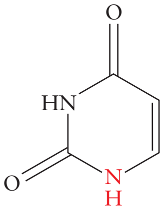
23 Guanine



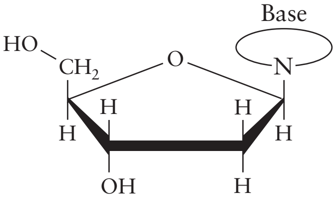
24 Cytosine



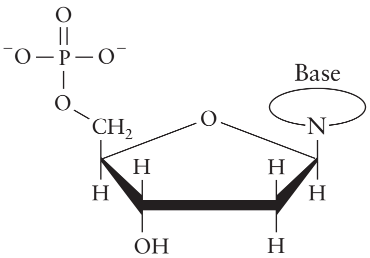
25 Thymine



26 Uracil



27 A nucleoside



28 A nucleotide

The DNA monomers are each completed by a phosphate group, —O—PO_3^{2-}, covalently bonded to carbon atom 5 of the ribose unit to give a compound called a **nucleotide** (**28**). Because there are four possible nucleoside monomers (one for each base), there are four possible nucleotides in each type of nucleic acid.

Molecules of DNA and RNA are **polynucleotides,** polymeric species built from nucleotide units. Polymerization takes place when the phosphate group of one nucleotide (which is the conjugate base of an organic phosphoric acid) condenses with the —OH group on carbon atom 3 of the ribose unit of another nucleotide, thereby forming an ester link and releasing a molecule of water. As this condensation continues, it results in a structure like that shown in Fig. 19.29, a compound known as a **nucleic acid.** The DNA molecule itself is a double helix in which two long nucleic acid strands are wound around each other.

The ability of DNA to replicate lies in its double-helical structure. There is a precise correspondence between the bases in the two strands. Adenine in one strand always forms two hydrogen bonds to thymine in the other, and guanine always forms three hydrogen bonds to cytosine; so, across the helix, the base pairs are always AT and GC (Fig. 19.30). Any other combination would not be held together as well. During replication of the DNA, the hydrogen bonds, which are relatively weak compared with the

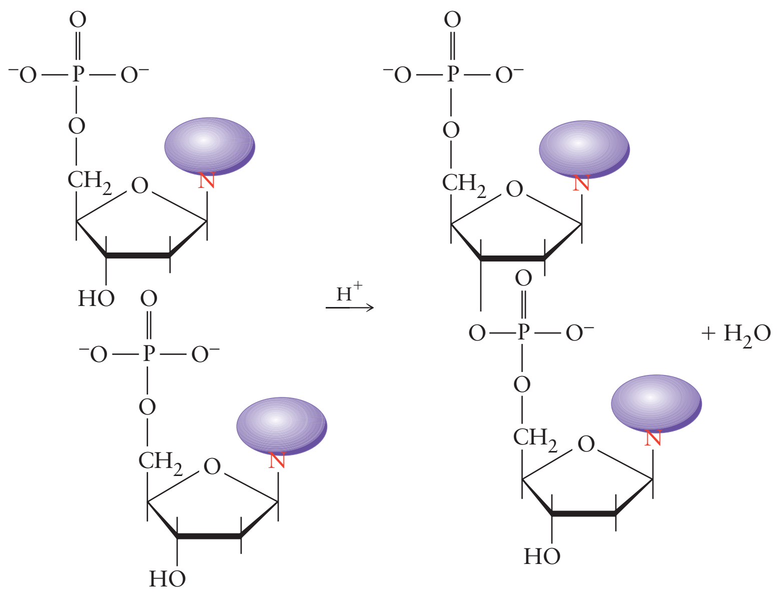


FIGURE 19.29 The condensation of nucleotides that leads to the formation of a nucleic acid, a polynucleotide.

covalent bonds in the strands, can be broken by an enzyme while the strands themselves remain intact. Nucleotides in the cellular fluid then attach in the appropriate places on each strand to form the double helices of two new molecules of DNA.

As well as replication—the production of copies of itself for reproduction and cell division—DNA governs the production of proteins by serving as the template during the synthesis of molecules of RNA. The RNA molecules, with U in place of T, are considered to be "messenger" molecules, because they carry information about segments of the genetic message out of the cell nucleus to the locations where protein synthesis takes place. In this way, the chemical reactions of functional groups, and in a broader sense, the principles of chemistry, bring matter to life.

Nucleic acids are copolymers of four nucleotides joined by phosphate ester links. The nucleotide sequence stores all genetic information.

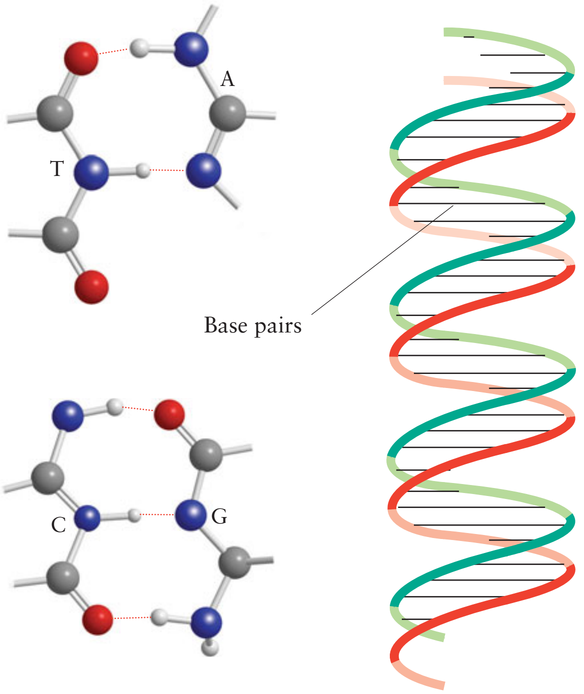

FIGURE 19.30 The bases in the DNA double helix fit together by virtue of the hydrogen bonds that they can form, as shown on the left. Once formed, the AT and GC pairs are almost identical in size and shape. As a result, the turns of the helix shown on the right are regular and consistent.

SKILLS YOU SHOULD HAVE MASTERED

❑ 1 Recognize a simple haloalkane, alcohol, ether, phenol, aldehyde, ketone, carboxylic acid, amine, amide, or ester, given a molecular structure.

❑ 2 Predict the oxidation products of aldehydes and ketones (Section 19.5).

❑ 3 Write the structural formula of an ester or an amide formed from the condensation reaction of a given carboxylic acid with a given alcohol or amine (Sections 19.7 and 19.8).

❑ 4 Predict the influence of hydrogen bonding on the physical properties of organic compounds (Self-Test 19.2).

❑ 5 Name simple functional groups (Toolbox 19.1 and Example 19.1).

❑ 6 Predict the type of polymer that a given monomer can form and identify monomers, given the repeating unit of a polymer (Example 19.2).

❑ 7 Distinguish the various types of copolymers (Self-Test 19.5).

❑ 8 Explain the role of chain length, crystallinity, network formation, cross-linking, and intermolecular forces in determining the physical properties of polymers (Section 19.12).

❑ 9 Describe the composition of proteins and distinguish their primary, secondary, tertiary, and quaternary structures (Section 19.13).

❑ 10 Describe the composition of carbohydrates (Section 19.14).

❑ 11 Describe the structures and functions of nucleic acids (Section 19.15).

EXERCISES

Identifying Functional Groups and Naming Their Compounds

19.1 Write the general formula of each of the following types of compounds, using R to denote an organic group: (a) amine; (b) alcohol; (c) carboxylic acid; (d) aldehyde.

19.2 Write the general formula of each of the following types of compounds, using R to denote an organic group: (a) ether; (b) ketone; (c) ester; (d) amide.

19.3 Identify each type of compound: (a) R—O—R; (b) R—CO—R; (c) $R—NH_2$; (d) R—COOR.

19.4 Identify each type of compound: (a) R—CHO; (b) R—COOH; (c) R—CONHR; (d) R—OH.

19.5 Name the following compounds: (a) $CH_3CHClCH_3$; (b) $CH_3CH_2C(CH_3)ClCH_2CHClCH_3$; (c) CH_3CI_3; (d) CH_2Cl_2.

19.6 Name the following compounds: (a) CH_3CH_2CHO; (b) $CH_2CHCH_2CH_2OH$; (c) $CH_3CCCH_2CH_2CH_2Cl$; (d) $CH_3CH_2COCH_2CH_2CH_3$.

19.7 Write the formulas of the following compounds and state whether each one is a primary, secondary, or tertiary alcohol or a phenol: (a) 1-chloro-2-hydroxybenzene; (b) 2-methyl-3-pentanol; (c) 2,4-dimethyl-1-hexanol; (d) 2-methyl-2-butanol.

19.8 Write the formulas of the following compounds and state whether each one is a primary, secondary, or tertiary alcohol or a phenol: (a) 2-methyl-1-propanol; (b) 2-propanol; (c) *p*-hydroxytoluene; (d) 1-bromo-2-(hydroxymethyl)benzene.

19.9 Write the formula of (a) ethyl methyl ether, (b) ethyl propyl ether; (c) dimethyl ether.

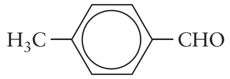
19.10 Write the formula of (a) dipropyl ether; (b) dipentyl ether; (c) ethyl propyl ether.

19.11 Name each compound: (a) $CH_3CH_2CH_2OCH_2CH_2CH_2CH_3$; (b) $C_6H_5OCH_3$; (c) $CH_3CH_2CH_2OCH_2CH_2CH_2CH_2CH_3$.

19.12 Name each compound: (a) $CH_3CH_2CH_2OCH_3$; (b) $CH_3CH_2OCH_2CH_2CH_2CH_2CH_3$; (c) $CH_3CH_2CH_2CH_2OCH_2CH_2CH_2CH_3$.

19.13 Identify each compound as an aldehyde or a ketone and give its systematic name: (a) CH_3CHO; (b) CH_3COCH_3; (c) $(CH_3CH_2)_2CO$.

19.14 Identify each compound as an aldehyde or a ketone and give its systematic name: (a) CH_3CH_2CHO;
(b)



(c) $(CH_3CH_2)_2CHCH_2COCH_3$

19.15 Write the structural formula of (a) butanal; (b) 3-hexanone; (c) 2-heptanone.

19.16 Write the structural formula of (a) 2-ethyl-2-methylpentanal; (b) 3,5-dihydroxy-4-octanone; (c) 4,5-dimethyl-3-hexanone.

19.17 Give the systematic name of (a) CH_3COOH; (b) $CH_3CH_2CH_2COOH$; (c) $CH_2(NH_2)COOH$.

19.18 Give the systematic name of (a) $CH_3CH(CH_3)CH_2COOH$; (b) CH_2ClCH_2COOH; (c) $CH_3(CH_2)_7COOH$.

19.19 Draw the structure of (a) benzoic acid, C_6H_5COOH; (b) 2-chloro-3-methylpentanoic acid; (c) hexanoic acid; (d) propenoic acid.

19.20 Draw the structure of (a) 2-methylpropanoic acid; (b) 2,2-dichlorobutanoic acid; (c) 2,2,2-trifluoroethanoic acid; (d) 4,4-dimethylpentanoic acid.

19.21 Give the systematic name of each of the following amines: (a) CH_3NH_2; (b) $(CH_3CH_2)_2NH$; (c) *o*-$CH_3C_6H_4NH_2$.

19.22 Give the systematic name of each of the following amines: (a) $CH_3CH_2CH_2NH_2$; (b) $(CH_3CH_2)_4N^+$; (c) *p*-$ClC_6H_4NH_2$.

19.23 Write the structural formula of each of the following amines: (a) *o*-methylphenylamine; (b) triethylamine; (c) tetramethylammonium ion.

19.24 Write the structural formula of each of the following amines: (a) methylpropylamine; (b) dimethylamine; (c) *m*-methylphenylamine.

Reactivity Patterns and Functional Groups

19.25 Which of the following molecules or ions may function as a nucleophile in a nucleophilic substitution reaction: (a) NH_3; (b) CO_2; (c) Br^-; (d) SiH_4?

19.26 Which of the following molecules or ions may function as a nucleophile in a nucleophilic substitution reaction: (a) OH^-; (b) NH_4^+; (c) NH_2^-; (d) H_2O?

19.27 Suggest an alcohol that could be used for the preparation of each of the following compounds and indicate how the reaction would be carried out; (a) ethanal; (b) 2-octanone; (c) 5-methyloctanal.

19.28 Suggest an alcohol that could be used for the preparation of each of the following compounds and indicate how the reaction would be carried out: (a) propanal; (b) 2-pentanone; (c) 5-ethyl-3-nonanone.

19.29 Draw the structure of the principal product formed from each of the following condensation reactions: (a) butanoic acid with 2-propanol; (b) ethanoic acid with 1-pentanol; (c) hexanoic acid with methylethyl amine; (d) ethanoic acid with propylamine.

19.30 Draw the structure of the principal product formed from each of the following condensation reactions: (a) octanoic acid with methanol; (b) propanoic acid with ethanol; (c) propanoic acid with methylamine; (d) methanoic acid with diethylamine.

19.31 Classify each of the following reactions as (1) an addition reaction, (2) a nucleophilic substitution reaction, (3) an electrophilic substitution reaction, or (4) a condensation reaction: (a) the reaction of 1-butene with chlorine in the absence of light; (b) the polymerization of the amino acid glycine; (c) the hydrogenation of 1-butyne; (d) the polymerization of styrene, $CH_2CHC_6H_5$; (e) the reaction of methylamine with butanoic acid.

19.32 Classify each of the following reactions as (1) an addition reaction, (2) a nucleophilic substitution reaction, (3) an electrophilic substitution reaction, or (4) a condensation reaction: (a) the reaction of terephthalic acid with 1,2-ethanediol; (b) the reaction of 3-chlorohexane with concentrated sodium hydroxide; (c) the reaction of water with 2-iodo-2-methylpropane; (d) the reaction of propanoic acid with ethanol; (e) the reaction of toluene with bromine in the presence of $FeBr_3$.

19.33 You are given samples of propanal, 2-propanone, and ethanoic acid. Describe how you would use chemical tests, such as acid–base indicators and oxidizing agents, to distinguish among the three compounds.

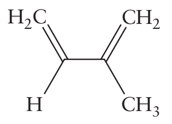
19.34 You are given samples of 1-propanol, pentane, and ethanoic acid. Describe how you would use chemical tests, such as aqueous solubility and acid–base indicators, to distinguish among the three compounds.

19.35 Rank the following acids in order of increasing acid strength: $ClCH_2COOH$, Cl_3CCOOH, CH_3COOH, and CH_3CH_2COOH. Justify your answer.

19.36 Rank methylamine, dimethylamine, and diethylamine in order of increasing base strength. Explain your rankings in relation to molecular structure.

Polymers

19.37 Sketch three repeating units of the polymer formed from (a) $CH_2{=}C(CH_3)_2$; (b) $CH_2{=}CHCN$; (c) isoprene,



.

19.38 Sketch three repeating units of the polymer formed from (a) tetrafluoroethene; (b) phenylethene; (c) $CH_3CH{=}CHCH_3$.

19.39 A polyamide has the repeating unit $-(COC_6H_{12}CONHC_6H_4NH)_n-$. Identify the monomers of the polyamide.

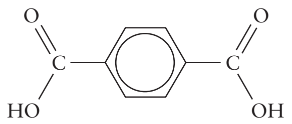
19.40 A polyester has the repeating unit $-(OCH_2C_6H_4CH_2OOCC_6H_4CO)_n-$. Identify the monomers of the polyester.

19.41 Write the structural formulas of the monomers of each of the following polymers, for which one repeating unit is shown: (a) polyvinylchloride (PVC), $-(CHClCH_2)_n-$; (b) Kel-F, $-(CFClCF_2)_n-$.

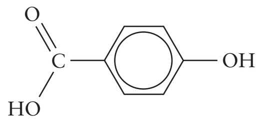
19.42 Write the structural formulas of the monomers of each of the following polymers, for which one repeating unit is shown: (a) a polymer used to make carpets, $-(OC(CH_3)_2CO)_n-$; (b) $-(CH(CH_3)CH_2)_n-$; (c) a polypeptide, $-(NHCH_2CO)_n-$.

19.43 Write the structural formula of two units of the polymer formed from (a) the reaction of oxalic acid (ethanedioic acid), HOOCCOOH, with 1,4-diaminobutane, $H_2NCH_2CH_2CH_2CH_2NH_2$; (b) the polymerization of the amino acid alanine (2-aminopropanoic acid).

19.44 Write the structural formula of two units of the polymer formed from (a) the reaction of terephthalic acid with 1,2-diaminoethane, $H_2NCH_2CH_2NH_2$; (b) the polymerization of 4-hydroxybenzoic acid.



Terephthalic acid



4-Hydroxybenzoic acid

19.45 Identify the type of copolymer formed by monomers A and B: —BBBBAA—.

19.46 Identify the type of copolymer formed by monomers A and B: —AABABBAA—.

19.47 Why do polymers not have definite molar masses? How does the fact that polymers have average molar masses affect their melting points?

19.48 Rank the following polymers according to increasing value as fibers: polyesters, polyamides, polyalkenes. Explain your reasoning.

19.49 How does average molar mass (which is proportional to the chain length) affect each of the following polymer characteristics: (a) softening point; (b) viscosity; (c) strength?

19.50 How does the polarity of the side chains in a polymer affect each of the following characteristics of the polymer: (a) softening point; (b) viscosity; (c) strength?

19.51 Describe how the linearity of the polymer chain affects polymer strength.

19.52 Describe how cross-linking affects the elasticity and rigidity of a polymer.

Biological Compounds

19.53 (a) Draw the structure of the peptide bond that links the amino acids in proteins. (b) Identify the functional group formed. (c) Identify the type of polymer formed (addition or condensation).

19.54 (a) Draw the structure of the link between glucose units that creates amylose. (b) Identify the functional group formed. (c) Identify the type of polymer formed (addition or condensation).

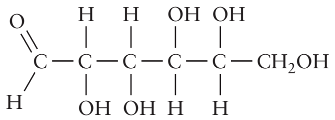
19.55 Name the amino acids in Table 19.4 that contain side groups capable of forming hydrogen bonds. This interaction contributes to the tertiary structure of a protein.

19.56 Name the amino acids in Table 19.4 that contain nonpolar side groups. These groups contribute to the tertiary structure of a protein by preventing contact with water.

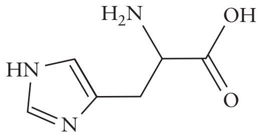
19.57 Draw the structure of the peptide formed from the reaction of the acid group of tyrosine with the amine group of glycine.

19.58 Draw the structure of the peptide formed from the reaction of the acid group of glycine with the amine group of tyrosine.

19.59 Identify (a) the functional groups and (b) the chiral carbon atoms in the mannose molecule shown here.



19.60 Identify (a) the functional groups and (b) the chiral carbon atoms in the histidine molecule shown here.

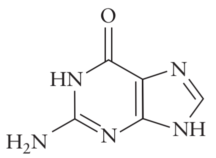


19.61 Write the complementary nucleic acid sequence that would pair with each of the following DNA sequences:
(a) CATGAGTTA; (b) TGAATTGCA.

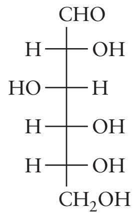
19.62 Write the complementary nucleic acid sequence that would pair with each of the following DNA sequences:
(a) ATTAGATCAT; (b) GACTAGGATCT.

Integrated Exercises

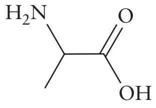
19.63 Write the chemical formula of the compound represented by each of the following line structures:



(a) Guanine

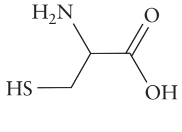


(b) D-Glucose

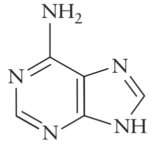


(c) Alanine

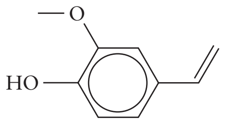
19.64 Write the chemical formula of the compound represented by each of the following line structures:



(a) Cysteine

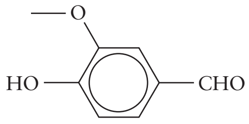


(b) Adenine

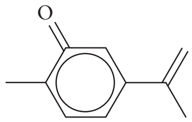


(c) Eugenol

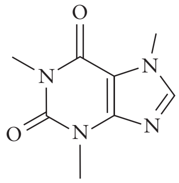
19.65 Identify all the functional groups in each of the following compounds:
(a) vanillin, the compound responsible for vanilla flavor,



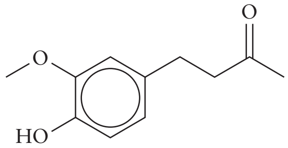
(b) carvone, the compound responsible for spearmint flavor,



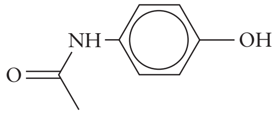
(c) caffeine, the stimulant in coffee, tea, and cola drinks,



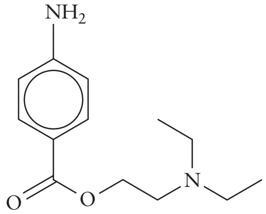
19.66 Identify all the functional groups in each of the following compounds:
(a) zingerone, the pungent, hot component of ginger,



(b) Tylenol, an analgesic,

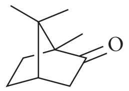


(c) procaine, a local anesthetic,

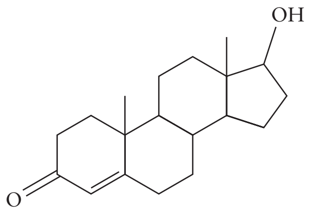


19.67 Identify the chiral carbon atoms in each of the following compounds:

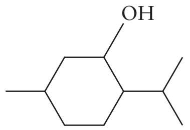
(a) camphor, used in cooling salves,



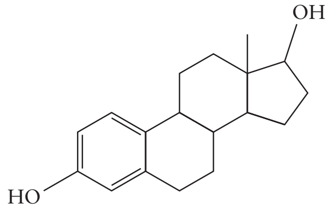
(b) testosterone, a male sex hormone,



19.68 Identify the chiral carbon atoms in each of the following compounds:
(a) menthol, the flavor of peppermint,



(b) estradiol, a female sex hormone,



19.69 The structures of the following molecules can be found on the Web site for this text. Draw the structure of each and identify its chiral carbon atoms: (a) cocaine; (b) aflatoxin B2, a toxin and carcinogen that occurs naturally in peanuts as a by-product of the growth of fungi.

19.70 The structures of the following molecules can be found on the Web site for this text. Draw the line structure of each and identify its chiral carbon atoms: (a) cephalosporin C, toxic to penicillin-resistant staphylococci; (b) thromboxane A2, a substance that promotes the clotting of blood.

19.71 Three compounds that could be produced biologically and used as fuels are methylamine, H_2NCH_3, a gas that occurs in herring brines and animal urine, dimethyl ether, CH_3OCH_3, a gas that can be produced from methanol, and acetic acid, H_3CCOOH, a liquid ($\Delta H_{vap} = 23.70$ kJ·mol^{-1}) obtained from the fermentation of sugars. (a) Draw the Lewis structures of each of these compounds. (b) Use bond enthalpies to calculate the specific enthalpy of combustion of each fuel (the enthalpy of combustion per gram of fuel), assuming that they burn to produce gaseous CO_2, liquid H_2O, and in the case of glycine, N_2. (c) Look up these compounds and their toxicity in reference books such as *The Merck Index* or the *Handbook of Chemistry and Physics*. Would any make a useful fuel in their pure form?

19.72 A carbon tax has been proposed to limit emissions of carbon dioxide. If fuel were taxed at the rate of $100 per tonne (1 t = 10^3 kg) of carbon, what would be the tax on 10.0 kg of (a) methane, (b) octane, a major component of gasoline, (c) ethanol, (d) peat (approximately 50% carbon), (e) anthracite coal (approximately 95% carbon).

19.73 (a) Write the structural formulas of diethyl ether and 1-butanol (note that they are isomers). (b) The boiling point of 1-butanol is 117°C, higher than that of diethyl ether (35°C), yet the solubility of both compounds in water is about 8 g per 100 mL. Account for these observations.

19.74 Consider the following organic molecules, which have approximately the same molar masses but contain different functional groups: $CH_3CH_2CH_2CH_2CH_2CH_3$, $CH_3CH_2CH_2CH_2CHCH_2$, $CH_3CH_2CH_2CH_2CH_2OH$, $CH_3CH_2CH_2CH_2CHO$, $CH_3CH_2CH_2COOH$, $CH_3CH_2COOCH_3$, $CH_3CH_2COCH_2CH_3$, $CH_3CH_2CH_2CH_2OCH_3$. (a) Draw a Lewis structure for each molecule, name it, and classify it by functional group. (b) Which molecules are isomers of each other? Are any chiral? If so, which ones? (c) For each molecule, list the types of intermolecular forces that are present. (d) Use your answers to parts (a) and (b) to predict the relative boiling points, from lowest to highest.

19.75 Write the structural formula for the product of (a) the reaction of glycerol (1,2,3-trihydroxypropane) with stearic acid, $CH_3(CH_2)_{16}COOH$, to produce a saturated fat; (b) the oxidation of 4-hydroxybenzyl alcohol by sodium dichromate in an acidic organic solvent.

19.76 Pheromones are commonly called sex attractants, although they have other signaling functions, too. A pheromone of the queen bee is *trans*-$CH_3CO(CH_2)_5CH{=}CHCOOH$. (a) Write the structural formula of the pheromone. (b) Identify and name the functional groups in the molecule.

19.77 Write the condensed structural formulas of the principal products of the reaction that takes place when (a) ethylene glycol, 1,2-ethanediol, is heated with stearic acid, $CH_3(CH_2)_{16}COOH$; (b) ethanol is heated with oxalic acid, HOOCCOOH; (c) 1-butanol is heated with propanoic acid.

19.78 The pK_a values for phenol, *o*-nitrophenol, *m*-nitrophenol, and *p*-nitrophenol are 9.89, 7.17, 8.28, and 7.15, respectively. Explain the origin of these differences in pK_a.

19.79 Acrylic resins are polymeric materials used to make warm yet lightweight garments. The osmotic pressure of a solution prepared by dissolving 47.7 g of an acrylic resin in enough water to make 500. mL of solution is 0.325 atm at 25°C. (a) What is the average molar mass of the polymer? (b) How many monomers constitute the "average" molecule? The repeating unit of this acrylic resin has the formula —$CH_2CH(CN)$—. (c) What would be the vapor pressure of the solution if the vapor pressure of pure water at 25°C is 0.0313 atm? (Assume that the density of the solution is 1.00 g·cm^{-3}.) (d) Which approach (osmometry or the lowering of vapor pressure) would you prefer for the determination of very high molar masses such as those of acrylic resins? Why?

19.80 The average molar mass of a sample of polypropylene was determined by measuring the osmotic pressure of 500. mL of a solution of 3.16 g of polypropylene in benzene. A pressure of 0.0112 atm was observed at 25°C. (a) What is the average molar mass of the polymer? (b) How many propene monomer units with formula —$CH(CH_3)CH_2$— were combined on average to create each chain? (c) If this sample consists only of linear chains and the carbon–carbon bond lengths in the polymer are close to their average value, what is the average chain length?

19.81 (a) Explain the differences among the primary, secondary, tertiary, and quaternary structures of a protein. (b) Identify the forces holding each structure together as covalent bonds or primarily intermolecular forces.

19.82 Haloalkanes may react with hydroxide ions, undergoing nucleophilic displacement of the halide ion to form an alcohol. A complication of such reactions is competition from elimination reactions rather than substitution (see Section 18.5). (a) Predict the possible products from the reaction of 2-bromopentane with sodium hydroxide. (b) What can be done to favor the substitution reaction over the elimination pathway or vice versa?

19.83 The protonated form of glycine ($^+H_3NCH_2COOH$) has $K_{a1} = 4.47 \times 10^{-3}$, and $K_{a2} = 1.66 \times 10^{-10}$. (a) Write the chemical equations for the proton transfer equilibria. (b) What is the dominant form of glycine in solution at pH = 2, pH = 5, and pH = 12?

19.84 In the amide group, rotation is restricted about the C—N bond, so that the C, N, and O atoms in that group are normally in the same plane. This rigidity helps to form the primary structure of proteins. The amino acid glycine can form a dipeptide, composed of two glycine monomers. (a) Draw the Lewis structure of the glycine dipeptide. (b) Explain how resonance structures can account for the restricted rotation and draw a second resonance structure for the dipeptide.

19.85 Explain the process of condensation polymerization. How might the polymer obtained from benzene-1,2-dicarboxylic acid and ethylene glycol differ from Dacron?

19.86 The average molar mass of a hydrogen-bonded pair of nucleotides in a DNA molecule is 625 $g\cdot mol^{-1}$. Each successive pair is found at a distance of 340 pm along the chain. If the total length of one strand of a DNA molecule is 0.299 m, what is the molar mass of the molecule?

19.87 A segment of a protein is analyzed and found to contain the amino acid sequence Glu-Leu-Asp. Draw the Lewis structure of this segment, showing the peptide bonds.

19.88 Ferritin is a globular iron-storage protein that stores iron as Fe^{3+}. To leave the ferritin, Fe^{3+} must first be reduced to Fe^{2+}. Ferritin has two types of channels through which the Fe^{2+} could leave: a "three-fold channel" and a "four-fold channel." The three-fold channel is lined with the amino acids aspartate (Asp) and glutamate (Glu) and the four-fold channel is lined with the amino acid leucine (Leu). Through which channel is the Fe^{2+} more likely to leave the ferritin protein? Explain your answer.

19.89 A silicone oil being studied for use in artificial limbs has a structure in which each silicon atom in the $—(O—Si—O—Si—)_n—$ backbone is attached to two methyl groups (see Fig. 19.18). Draw the molecular structure of three repeating units of this oil.

19.90 The polyphosphazenes, which are being used as heat-resistant polymers in the aerospace industry and as flexible scaffolds for bone regeneration, are inorganic polymers with the repeating unit $(—PR_2{=}N—)_n$, in which R stands for side chains such as $—CH_3$ groups. How would you expect the properties of the polyphosphazene with methyl group side chains to differ from those of the corresponding silicone polymer (see Fig. 19.18)? Explain your reasoning.

19.91 The monomer of the conducting polymer polyaniline is the compound aniline (aminobenzene). (a) Draw the structural formula of the aniline monomer. What is the hybridization of the N atom in (b) aniline? (c) polyaniline? (d) Indicate the locations of lone pairs, if any, in polyaniline. (e) Do the N atoms help to carry the current? Explain your reasoning. See Box 19.1.

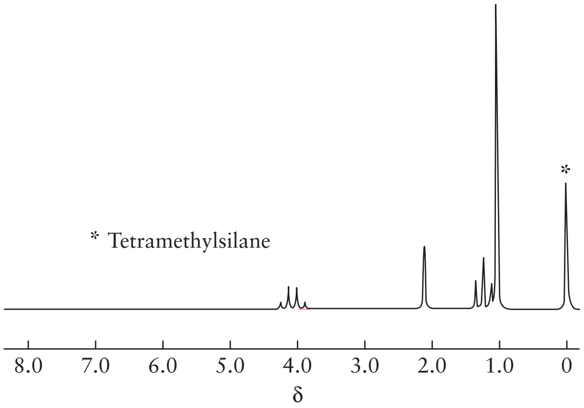
19.92 Fibers of the conducting polymer polypyrrole are woven into radar camouflage cloth. Because it absorbs microwaves, rather than reflecting them back to their source, the cloth appears to be a patch of empty space on radar. (a) What is the hybridization of the N atom in polypyrrole? (b) Explain why polypyrrole absorbs microwave radiation, but small organic molecules do not. See Box 19.1 for the structure of polypyrrole.

For the following nine exercises, see Major Technique 7, Nuclear Magnetic Resonance, following this chapter.

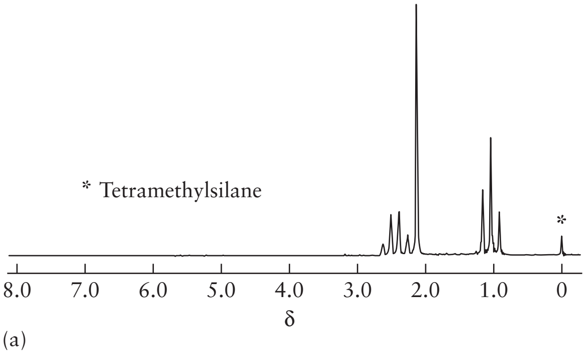
19.93 Predict the features of the ^{1}H NMR spectrum of ethanal, CH_3CHO.

19.94 Predict the features of the ^{1}H NMR spectrum of propane.

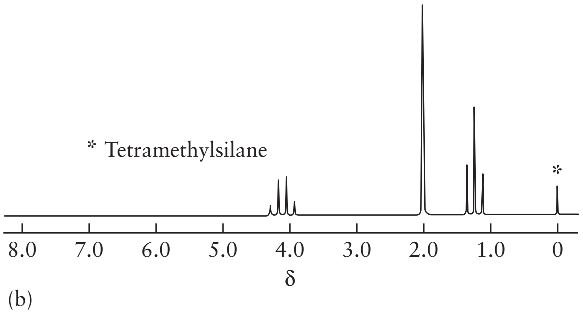
19.95 Explain the features of the following ^{1}H NMR spectrum of ethyl-3,3-dimethylbutanoate.



19.96 The ^{1}H NMR spectra of (a) 2-butanone and (b) ethyl acetate are shown here. The spectra are very similar yet have some important differences. Explain the observed similarities and differences.

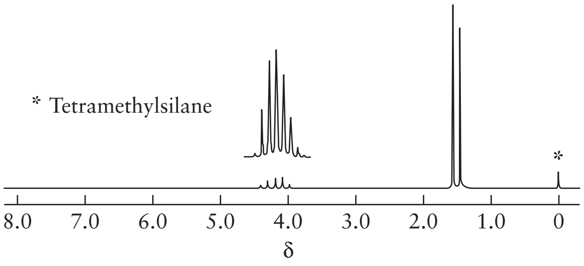


(a)



(b)

19.97 When propane is treated with chlorine gas, a mixture of compounds results. The mixture is separated and analysis of one of the components gives the ^{1}H NMR spectrum shown here. What is this product?



19.98 Other nuclei besides the proton have a nuclear spin of $\frac{1}{2}$ and, in principle at least, may be suitable for nuclear magnetic resonance spectroscopy. From standard literature sources, find at

least five other naturally occurring, nonradioactive elements that have spin of $\frac{1}{2}$ and that can be examined by NMR spectroscopy.

19.99 One naturally occurring isotope of carbon is suitable for NMR spectroscopy. (a) From literature sources, determine which isotope of carbon has a spin of $\frac{1}{2}$. (b) What is the natural abundance of this isotope of carbon? (c) Given that only nuclei having a nuclear spin may interact to produce fine structure in an NMR spectrum, do you expect to see the splitting due to interactions between adjacent carbon atoms in an organic molecule such as propane in its carbon NMR spectrum? (d) Do you expect to see splitting of the proton signal in the ^1H NMR spectrum of propane due to the interactions between the carbon and the proton nuclei? (e) Do you expect to see splitting of the carbon signal in the carbon NMR spectrum of propane due to the interactions between the carbon and the proton nuclei?

19.100 Predict the features of the ^1H NMR spectra of benzene and the three isomeric dichlorobenzenes. Is it possible to distinguish the isomeric dichlorobenzenes on the basis of their NMR spectra alone?

19.101 The NMR spectrum of a compound can reveal whether the atoms within the molecule are equivalent or different. For example, the hydrogen atoms in $CH_2{=}CH_2$ are equivalent: they all exist in an identical environment. However, in $CH_2{=}CHCl$, the two hydrogen atoms attached to the same carbon atom are equivalent, but different from the hydrogen atom on the other carbon atom. Predict how many different types of hydrogen atoms can be identified in the ^1H NMR spectrum of each of the following molecules: (a) C_2H_2; (b) *cis*-$C_2H_2Cl_2$; (c) *trans*-$C_2H_2Cl_2$; (d) CH_3OH. (e) In the molecule C_2H_5Cl, the hydrogen atoms would all be different if the molecule existed in only one conformation. However, only two types of hydrogen atoms are detected. Propose an explanation.

Chemistry Connections

19.102 Waste reduction is an important goal of the green chemistry movement. In many chemical syntheses in industry, not all the atoms required for the reaction appear in the product. Some end up in by-products and are wasted. "Atom economy" is the use of as few atoms as possible to reach an end product and is calculated as a percentage, using atom economy = (mass of desired product obtained)/(mass of all reactants consumed) × 100%.

(a) Consider the following synthesis of $CH_3CH{=}CHCH_3$:

$$CH_3CH_2CHBrCH_3 + CH_3CH_2O^- \xrightarrow{\text{ethanol}} CH_3CH{=}CHCH_3 + CH_3CH_2OH + Br^-$$

Identify the type of reaction (substitution, elimination, addition).

(b) Name each organic reactant and product.

(c) Does the $CH_3CH_2O^-$ ion function as a nucleophile, an electrophile, or neither?

(d) Calculate the atom economy of the reaction, assuming 100% yield.

(e) An alternative synthesis of $CH_3CH{=}CHCH_3$ is

$$CH_3CH_2CHBrCH_3 + CH_3O^- \xrightarrow{\text{methanol}} CH_3CH{=}CHCH_3 + CH_3OH + Br^-$$

Calculate the atom economy for the reaction, assuming 100% yield.

(f) Another alternative synthesis of $CH_3CH{=}CHCH_3$ is

$$CH_3CH_2CHBrCH_3 + CH_3S^- \xrightarrow{\text{methanethiol}} CH_3CH{=}CHCH_3 + CH_3SH + Br^-$$

Calculate the atom economy for the reaction, assuming 100% yield.

(g) Which of the three syntheses produces the lowest mass of waste? Which produces the highest?

(h) Assume that you carry out each of the three syntheses, starting with 50.0 g of $CH_3CH_2CHBrCH_3$ and with the second reagent in excess in each case. Your yields of $CH_3CH{=}CHCH_3$ for the three reactions are as follows: (a) 16.2 g; (e) 15.4 g; (f) 13.1 g. Calculate the percentage yield and experimental atom economy for each reaction.

(i) Which reaction would you recommend to a manufacturer? Explain your reasoning.

Nuclear magnetic resonance (NMR) is the principal technique for the identification of organic compounds and is among the leading techniques for the determination of their structures. The technique has also been developed, as *magnetic resonance imaging* (MRI), as a diagnostic procedure in medicine.

The Technique

Many atomic nuclei behave like small bar magnets, with energies that depend on their orientation in a magnetic field. An NMR spectrometer detects transitions between these energy levels. The nucleus most widely used for NMR is the proton, and we shall concentrate on it. Two other very common nuclei, those of carbon-12 and oxygen-16, are nonmagnetic, so they are invisible in NMR.

Like an electron, a proton possesses the property of spin, which for elementary purposes can be thought of as an actual spinning motion. Because a proton has an electric charge and because a moving charge generates a magnetic field, a proton acts as a tiny bar magnet that can have either of two orientations, which are denoted ↑ (or α) and ↓ (or β). In the presence of a magnetic field these two orientations have different energies.

If the sample is exposed to electromagnetic radiation, the nuclei are flipped from one orientation to another when the energy of the incoming photons (which is $h\nu$, where ν is the frequency of the radiation) matches the energy separation of the two spin orientations. The strong coupling between nuclei and radiation that occurs when this condition is satisfied is called *resonance*. At resonance, the radiation is strongly absorbed and a sharp peak appears in the detector output. Superconducting magnets are used to generate very high magnetic fields, and resonance requires radio-frequency radiation at about 500 MHz.

Each proton in a compound comes into resonance at a frequency related to its location in the molecule. Figure 1, for instance, shows the NMR spectrum of ethanol; and we see that there are three groups of peaks and a characteristic pattern of splitting within the groups. Because all compounds that contain hydrogen give a characteristic NMR fingerprint, or pattern of peaks, many can be recognized by comparing the observed pattern with a library of patterns from known substances or by calculating the expected pattern of lines.

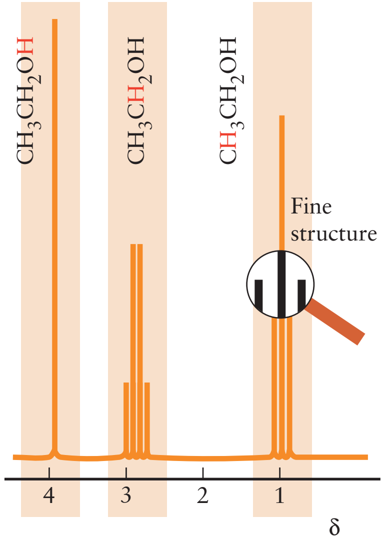


FIGURE 1 The NMR spectrum of ethanol. The red letters denote the protons that give rise to the associated peaks.

The Chemical Shift

The separation of the absorption into groups of lines is due to the different proton environments within the molecule. Thus, in ethanol, CH_3CH_2OH, three protons are present in the methyl group (CH_3), two are present in the methylene group (CH_2), and one is present in the hydroxyl group (OH). The applied magnetic field acts on the electrons in these three groups and causes them to circulate throughout the nuclear framework. These circulating charged particles give rise to an additional magnetic field, and so the protons in each of the three groups experience a local magnetic field that is not the same as the applied magnetic field. Because the electronic structure in each of the groups is different, the protons in each group experience slightly different local magnetic fields. As a result, slightly different radio-frequency fields are needed to bring them into resonance, and three groups of peaks are observed in the NMR spectrum.

We say that each group of protons has a characteristic *chemical shift*. The measurement of the chemical shift helps to identify the type of group responsible for the absorption and indicates what groups are present in the molecule. The chemical shift of a group of lines is expressed in terms of the δ *scale* (delta scale), which measures the difference in absorption frequency between the sample (ν) and a standard ($\nu°$):

$$\delta = \frac{\nu - \nu°}{\nu°} \times 10^6$$

The standard is typically tetramethylsilane, $Si(CH_3)_4$, which has a lot of protons and dissolves in many samples without reaction. Each group has a characteristic chemical shift, although the precise value depends on the other groups attached to the group of interest. For instance, if we observe a resonance at $\delta = 1$, we can be reasonably confident that it arises from a methyl group in an alcohol.*

The intensities (heights) of the peaks are proportional to the numbers of protons that they represent. The three peaks in the ethanol spectrum, for example, have overall intensities in the ratio 3 : 2 : 1, which is what we would expect for the three methyl, two methylene, and one hydroxyl protons.

(*continued*)

The Fine Structure

The *fine structure* of the spectrum is the splitting of the resonance into sharp peaks. Note that the methyl resonance in ethanol at $\delta = 1$ consists of three peaks with intensities in the ratio 1 : 2 : 1. The fine structure arises from the presence of other magnetic nuclei close to the protons undergoing resonance. The fine structure of the methyl group in ethanol, for instance, arises from the presence of the protons in the neighboring methylene group.

Let's imagine that we are a proton in the methyl group in ethanol and can sense the spins of the two neighboring methylene ($-CH_2-$) group protons. There are four possible orientations of these two spins: αα, αβ, βα, and ββ. Suppose our neighbors have αα spins. This arrangement gives rise to a magnetic field that we experience in addition to the applied magnetic field; so we (the methyl protons) come into resonance at the corresponding frequency. If we are in a molecule in which our neighbors are ββ, we experience a different local magnetic field, and we come into resonance at a different frequency. If our neighbors happen to be either αβ or βα, the magnetic field arising from the α spin cancels the field arising from the β spin; so the local field that we experience is the same as it would be in the absence of any neighbors, and we resonate at the characteristic frequency. Because there are two arrangements that give this resonance (αβ and βα), the central line of the resonance will be twice as intense as the two outer lines (which arise when our neighbors are αα and ββ, respectively). Thus, we expect a 1 : 2 : 1 fine structure, just as observed. If there are three equivalent protons in a nearby group (as there are for ethanol's methylene group resonance, because the methylene group has a methyl group as a neighbor), we expect four lines in the intensity ratio 1 : 3 : 3 : 1, just as observed. Four equivalent neighboring protons would yield lines in the intensity ratio 1 : 4 : 6 : 4 : 1, five would produce intensities in the ratios 1 : 5 : 10 : 10 : 5 : 1, and so on.

The hydroxyl resonance is not split by the other protons in the molecule because its proton is very mobile: it can jump from one ethanol molecule to another ethanol molecule or to any water molecules present. As a result, the proton does not stay on one molecule long enough to show any characteristic splitting or to give rise to splitting in other groups.

Magnetic Resonance Imaging

Magnetic resonance imaging is a noninvasive structural technique for complex systems of molecules, such as people. In its simplest form, MRI portrays the concentration of protons in a sample. If the sample—which may be a living human body—is exposed to a uniform magnetic field in an NMR spectrometer and if we work at a resolution that does not show any chemical shifts or fine structure, then the protons give rise to a single resonance line. However, if the magnetic field varies linearly across the sample, the protons will resonate at different frequencies according to their location in the field. Moreover, the intensity of the resonance at a given field will be proportional to the number of protons at the spatial location corresponding to that particular field value. If the field gradient is rotated into different orientations, another portrayal of the concentration of protons through the sample is obtained. After several such measurements of the absorption intensity, the data can be analyzed on a computer, which constructs a two-dimensional image of any section, or "slice" through the sample. Figure 2 shows the distribution of protons—in large measure, the distribution of water in a brain—and the different regions can be identified. A major advantage of MRI over x-rays is that, if a series of slices are obtained, they can be assembled into a three-dimensional image that yields a much more accurate image of soft tissues than is possible with x-rays.

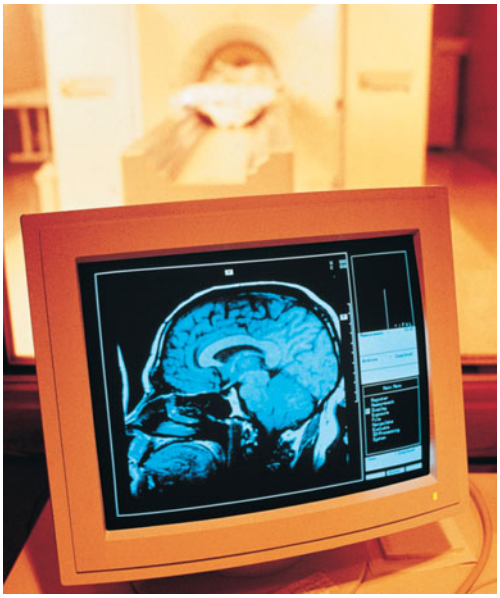

FIGURE 2 An MRI image of a human brain. The patient must lie within the strong magnetic field. The detectors can be rotated around the patient's head, thereby allowing many different views to be recorded.

Related Exercises: 19.93–19.101

*Chemical shifts are sometimes expressed in parts per million, such as $\delta = 1$ ppm for the methyl resonance; ignore the ppm in calculations.

APPENDIX 1: Symbols, Units, and Mathematical Techniques

1A SYMBOLS

Each physical quantity is represented by an Italic or Greek symbol (thus, *m* for mass, not m). Table 1 lists most of the symbols used in this textbook together with their units (see also Appendix 1B). The symbols may be modified by attaching subscripts, as set out in Table 2. Fundamental constants are not included in the lists but can be found inside the back cover of the book.

TABLE 1 Common Symbols and Units

Symbol	Physical quantity	SI unit
α (alpha)	polarizability	$C^2\cdot m^2\cdot J^{-1}$
γ (gamma)	surface tension	$N\cdot m^{-1}$
δ (delta)	chemical shift	—
θ (theta)	colatitude	degree, rad
λ (lambda)	wavelength	m
μ (mu)	dipole moment	C·m
ν (nu)	frequency	Hz
Π (pi)	osmotic pressure	Pa
σ (sigma)	cross section	m^2
ϕ (phi)	azimuth	degree (°), rad
χ (chi)	electronegativity	—
ψ (psi)	wavefunction	$m^{-n/2}$ (in n dimensions)
a	activity	—
	van der Waals parameter	$L^2\cdot atm\cdot mol^{-2}$
	unit-cell parameter	m
A	area	m^2
	mass number	—
	Madelung constant	—
b	molality	$mol\cdot kg^{-1}$, "m"
	van der Waals parameter	$L\cdot mol^{-1}$
B	second virial coefficient	$L\cdot mol^{-1}$
C	heat capacity	$J\cdot K^{-1}$
	third virial coefficient	$L^2\cdot mol^{-2}$
c	molar concentration, molarity	$mol\cdot L^{-1}$, "M"
c_2	second radiation constant	K·m
d	density	$kg\cdot m^{-3}$ ($g\cdot cm^{-3}$)
	length of unit-cell diagonal	m
E	energy	J
	electrode potential	V
E_a	activation energy	$J\cdot mol^{-1}$ ($kJ\cdot mol^{-1}$)
E_{bind}	nuclear binding energy	J
E_{cell}	cell potential	V
E_{ea}	electron affinity	$J\cdot mol^{-1}$ ($kJ\cdot mol^{-1}$)
E_k	kinetic energy	J
E_p	potential energy	J
e	elementary charge	C
F	force	N
G	Gibbs free energy	J

TABLE 2 Subscripts for Symbols

Subscript	Meaning	Example (units)
a	acid	acidity constant, K_a
b	base	basicity constant, K_b
	boiling	boiling temperature, T_b (K)
B	bond	bond enthalpy, ΔH_B ($kJ\cdot mol^{-1}$)
bind	binding	binding energy, E_{bind} (eV)

(continued)

TABLE 2 Subscripts for Symbols (*continued*)

Subscript	Meaning	Example (units)
c	concentration	equilibrium constant, K_c
	combustion	enthalpy of combustion, ΔH_c ($kJ\cdot mol^{-1}$)
	critical	critical temperature, T_c (K)
e	nonexpansion (extra) work	electrical work, w_e (J)
f	formation	enthalpy of formation, ΔH_f ($kJ\cdot mol^{-1}$)
		formation constant, K_f
	freezing	freezing temperature, T_f (K)
fus	fusion	enthalpy of fusion, ΔH_{fus} ($kJ\cdot mol^{-1}$)
H	Henry	Henry's law constant, k_H
In	indicator	indicator constant, K_{In}
k	kinetic	kinetic energy, E_k (J)
L	lattice	lattice enthalpy, ΔH_L ($kJ\cdot mol^{-1}$)
m	molar	molar volume, $V_m = V/n$ ($L\cdot mol^{-1}$)
M	Michaelis	Michaelis constant, K_M
mix	mixing	enthalpy of mixing, ΔH_{mix} ($kJ\cdot mol^{-1}$)
p	potential	potential energy, E_p (J)
P	constant pressure	heat capacity at constant pressure, C_P ($J\cdot K^{-1}$)
r	reaction	reaction enthalpy, ΔH_r ($kJ\cdot mol^{-1}$)
s	specific	specific heat capacity, $C_s = C/m$ ($J\cdot K^{-1}\cdot g^{-1}$)
sol	solution	enthalpy of solution, ΔH_{sol} ($kJ\cdot mol^{-1}$)
sp	solubility product	solubility product, K_{sp}
sub	sublimation	enthalpy of sublimation, ΔH_{sub} ($kJ\cdot mol^{-1}$)
surr	surroundings	entropy of surroundings, S_{surr} ($J\cdot K^{-1}$)
tot	total	total entropy, S_{tot} ($J\cdot K^{-1}$)
V	constant volume	heat capacity at constant volume, C_V ($J\cdot K^{-1}$)
vap	vaporization	enthalpy of vaporization, ΔH_{vap} ($kJ\cdot mol^{-1}$)
w	water	water autoprotolysis constant, K_w
0	initial	initial concentration, $[A]_0$
	ground state	wavefunction, ψ_0

1B UNITS AND UNIT CONVERSIONS

Each physical quantity is reported as a multiple of a defined unit:

Physical quantity = numerical value × unit

For instance, a length may be expressed as a multiple of the unit of length, the meter, m; so we write $l = 2.0$ m. All units are denoted by roman letters, such as m for meter and s for second.

The Système International (SI) is the internationally accepted form of the metric system. It defines seven **base units** in terms of which all physical quantities can be expressed:

meter, m The meter, the unit of length, is the length of the path traveled by light during a time interval of 1/299 792 458 of a second.

kilogram, kg The kilogram, the unit of mass, is the mass of a standard cylinder maintained at a laboratory in France.

second, s The second, the unit of time, is 9 192 631 770 periods of a certain spectroscopic transition in a cesium-133 atom.

ampere, A The ampere, the unit of electric current, is defined in terms of the force exerted between two parallel wires carrying the current.

kelvin, K The kelvin, the unit of temperature, is 1/273.16 of the absolute temperature of the triple point of water.

mole, mol The mole, the unit of chemical amount, is the amount of substance that contains as many specified entities as there are atoms in exactly 12 g of carbon-12.

candela, cd The candela, the unit of luminous intensity, is defined in terms of a carefully specified source. We do not use the candela in this book.

Any unit may be modified by one of the prefixes given in Table 3, which denote multiplication or division by a power of 10 of the unit. Thus, 1 mm = 10^{-3} m and 1 MK = 10^6 K. Note that all the prefixes are upright (roman), not Italic.

TABLE 3 Typical SI Prefixes

prefix:	deca-	kilo-	mega-	giga-	tera-	peta-			
abbreviation:	da	k	M	G	T	P			
factor:	10	10^3	10^6	10^9	10^{12}	10^{15}			
prefix:	deci-	centi-	milli-	micro-	nano-	pico-	femto-	atto-	zepto-
abbreviation:	d	c	m	μ (mu)	n	p	f	a	z
factor:	10^{-1}	10^{-2}	10^{-3}	10^{-6}	10^{-9}	10^{-12}	10^{-15}	10^{-18}	10^{-21}

Derived units are combinations of the base units (Section A). Table 4 lists some derived units. Note that the names of units derived from the names of people all begin with a lowercase letter but the initial letter of their abbreviation is uppercase.

TABLE 4 Derived Units with Special Names

Physical quantity	Name of unit	Abbreviation	Definition
absorbed dose	gray	Gy	$J \cdot kg^{-1}$
dose equivalent	sievert	Sv	$J \cdot kg^{-1}$
electric charge	coulomb	C	$A \cdot s$
electric potential	volt	V	$J \cdot C^{-1}$
energy	joule	J	$N \cdot m$, $kg \cdot m^2 \cdot s^{-2}$
force	newton	N	$kg \cdot m \cdot s^{-2}$
frequency	hertz	Hz	s^{-1}
power	watt	W	$J \cdot s^{-1}$
pressure	pascal	Pa	$N \cdot m^{-2}$, $kg \cdot m^{-1} \cdot s^{-2}$
volume	liter	L	dm^3

It is often necessary to convert one set of units (for instance, calories for energy and inches for length) into SI units. Table 5 lists some common conversions; the values in boldface type are exact.

TABLE 5 Relations Between Units

Physical quantity	Common unit	Abbreviation	SI equivalent
mass	pound	lb	**0.453 592 37** kg
	tonne	t	**10^3** kg (**1** Mg)
	ton (short, U.S.)	ton	907.184 74 kg
	ton (long, U.K.)	ton	1016.046 kg
length	inch	in.	**2.54** cm
	foot	ft	**30.48** cm
volume	U.S. quart	qt	**0.946 352 5** L
	U.S. gallon	gal	**3.785 41** L
	Imperial quart	qt	**1.136 522 5** L
	Imperial gallon	gal	**4.546 09** L
time	minute	min	**60** s
	hour	h	**3600** s
energy	calorie (thermochemical)	cal	**4.184** J
	electronvolt	eV	$1.602\ 177 \times 10^{-19}$ J
	kilowatt-hour	kWh	**3.6×10^6** J
	liter-atmosphere	L·atm	**101.325** J
pressure	torr	Torr	133.322 Pa
	atmosphere	atm	**101 325** Pa (**760** Torr)
	bar	bar	**10^5** Pa
	pounds/square inch	psi	6894.76 Pa
power	horsepower	hp	**745.7** W
dipole moment	debye	D	$3.335\ 64 \times 10^{-30}$ C·m

As explained in Section A, to convert between units, we use a **conversion factor** of the form

$$\text{Conversion factor} = \frac{\text{units required}}{\text{units given}}$$

When using a conversion factor, we treat the units just like algebraic quantities: they are multiplied or canceled in the normal way. Thus, the units in the denominator of the conversion factor cancel the units in the original data, leaving the units in the numerator of the conversion factor.

The conversion of temperatures is carried out slightly differently. Because the Fahrenheit degree (°F) is smaller than a Celsius degree by a factor of $\frac{5}{9}$ (because there are 180 Fahrenheit degrees between the freezing point and boiling point of water but only 100 Celsius degrees between the same two points) and because 0°C coincides with 32°F, we use

$$\text{Temperature (°F)} = \left\{\tfrac{9}{5} \times \text{temperature (°C)}\right\} + 32$$

(The 32 is exact.) For example, to convert 37°C (blood temperature) into degrees Fahrenheit, we write

$$\text{Temperature (°F)} = \left\{\tfrac{9}{5} \times 37\right\} + 32 = 99$$

and the temperature is reported as 99°F. A more sophisticated way of expressing the same relation is to write

$$\text{Temperature/°F} = \left\{\tfrac{9}{5} \times \text{temperature/°C}\right\} + 32$$

In this expression, we treat temperature units like numbers and cancel them when it is appropriate. The same conversion then becomes

$$\begin{aligned}\text{Temperature/°F} &= \left\{\tfrac{9}{5} \times (37\text{°C})/\text{°C}\right\} + 32 \\ &= \left\{\tfrac{9}{5} \times 37\right\} + 32 = 99\end{aligned}$$

and multiplication through by °F gives

$$\text{Temperature} = 99\text{°F}$$

The corresponding expression for conversion between the Celsius and Kelvin scales is

$$\text{Temperature/°C} = \text{temperature/K} + 273.15$$

(The 273.15 is exact.) Note that the size of the degree Celsius is the same as that of the kelvin.

1C SCIENTIFIC NOTATION

In **scientific notation,** a number is written as $A \times 10^a$. Here A is a decimal number with one nonzero digit in front of the decimal point and a is a whole number. For example, 333 is written 3.33×10^2 in scientific notation, because $10^2 = 10 \times 10 = 100$:

$$333 = 3.33 \times 100 = 3.33 \times 10^2$$

We use

$$\begin{aligned}10^1 &= 10 \\ 10^2 &= 10 \times 10 = 100 \\ 10^3 &= 10 \times 10 \times 10 = 1000 \\ 10^4 &= 10 \times 10 \times 10 \times 10 = 10\,000\end{aligned}$$

and so on. Note that the number of zeros following 1 is equal to the power of 10.

Numbers between 0 and 1 are expressed in the same way, but with a negative power of 10; they have the form $A \times 10^{-a}$, with $10^{-1} = 0.1$, and so on. Thus, 0.0333 in decimal notation is 3.33×10^{-2} because

$$10^{-2} = \frac{1}{10} \times \frac{1}{10} = \frac{1}{100}$$

and therefore

$$0.033 = 3.33 \times \frac{1}{100} = 3.33 \times 10^{-2}$$

We use

$$\begin{aligned}10^{-2} &= 10^{-1} \times 10^{-1} = 0.01 \\ 10^{-3} &= 10^{-1} \times 10^{-1} \times 10^{-1} = 0.001 \\ 10^{-4} &= 10^{-1} \times 10^{-1} \times 10^{-1} \times 10^{-1} = 0.0001\end{aligned}$$

When a negative power of 10 is written out as a decimal number, the number of zeros following the decimal point is one less than the number (disregarding the sign) to which 10 is raised. Thus, 10^{-5} is written as a decimal point followed by $5 - 1 = 4$ zeros and then a 1:

$$\begin{aligned}10^{-5} &= 10^{-1} \times 10^{-1} \times 10^{-1} \times 10^{-1} \times 10^{-1} \\ &= 0.000\,01\end{aligned}$$

The digits in a reported measurement are called the **significant figures.** There are two significant figures (written 2 sf) in 1.2 cm^3 and 3 sf in 1.78 g. Fundamentals Section A describes how to find the number of significant figures in a measurement.

Some zeros are legitimately measured digits, but other zeros serve only to mark the place of the decimal point. Trailing zeros (the last ones after a decimal point), as in 22.0 mL, are significant, because they were measured. Thus, 22.0 mL has 3 sf. The "captive" zero in 80.1 kg is a measured digit, and so 80.1 kg has 3 sf. However, the leading digits in 0.0025 g are not significant; they are only placeholders used to indicate powers of 10, not measured numbers. We can see that they are only placeholders by reporting the mass as 2.5×10^{-3} g, which has 2 sf.

We distinguish between the results of measurements, which are always uncertain, and the results of *counting*, which are *exact*. For example, the report "12 eggs" means that there are exactly 12 eggs present, not a number somewhere between 11.5 and 12.5.

Some ambiguity arises with whole numbers ending in zero. Does a length reported as 400 m have 3 sf (4.00×10^2), 2 sf (4.0×10^2), or only 1 sf (4×10^2)? In such cases, the use

of scientific notation removes any ambiguity. If it is not convenient to use scientific notation, a final decimal point can be used to indicate that every digit to the left of the decimal is significant. Thus, 400 m is ambiguous and cannot be taken to have more than 1 sf unless other information is given. However, 400. m unambiguously has 3 sf.

Different rounding-off rules are needed for addition (and its reverse, subtraction) and multiplication (and its reverse, division). In both procedures, we round off the answers to the correct number of significant figures.

Rounding off In calculations, round *up* if the last digit is above 5 and round *down* if it is below 5. For numbers ending in 5, always round to the nearest even number. For example, 2.35 rounds to 2.4 and 2.65 rounds to 2.6. In a calculation with multiple steps, round off only in the final step; if possible, carry all digits in the memory of the calculator until that stage.

Addition and subtraction When adding or subtracting, make sure that the number of decimal places in the result is the same as the *smallest number of decimal places* in the data. For example, 0.10 g + 0.024 g = 0.12 g.

Multiplication and division When multiplying or dividing, make sure that the number of significant figures in the result is the same as the *smallest number of significant figures* in the data. For example, $(8.62\text{ g})/(2.0\text{ cm}^3) = 4.3\text{ g·cm}^{-3}$.

Integers and exact numbers In multiplication or division of a measured value by an integer or an exact number, the uncertainty of the result is determined by the measured value. Some unit conversion factors are defined exactly, even though they are not whole numbers. For example, 1 in. is defined as *exactly* 2.54 cm and the 273.15 in the conversion between Celsius and Kelvin temperatures is exact; so 100.000°C converts into 373.150 K.

Logarithms and exponentials The mantissa of a common logarithm (the digits following the decimal point, see Appendix 1D) has the same number of significant figures as the original number. Thus, log 2.45 = 0.389. A common antilogarithm of a number has the same number of significant figures as the mantissa of the original number. Thus, $10^{0.389} = 2.45$ and $10^{12.389} = 2.45 \times 10^{12}$. There is no simple rule for assessing the correct number of significant figures when natural logarithms are used: one way is to convert natural logarithms into common logarithms and then to use the rules just specified.

1D EXPONENTS AND LOGARITHMS

To multiply numbers in scientific notation, multiply the decimal parts of the numbers and add the powers of 10:

$$(A \times 10^a) \times (B \times 10^b) = (A \times B) \times 10^{a+b}$$

An example is

$$\begin{aligned}(1.23 \times 10^2) \times (4.56 \times 10^3) &= 1.23 \times 4.56 \times 10^{2+3} \\ &= 5.61 \times 10^5\end{aligned}$$

This rule also applies if the powers of 10 are negative:

$$\begin{aligned}(1.23 \times 10^{-2}) \times (4.56 \times 10^{-3}) &= 1.23 \times 4.56 \times 10^{-2-3} \\ &= 5.61 \times 10^{-5}\end{aligned}$$

The results of such calculations are then adjusted so that one digit precedes the decimal point:

$$\begin{aligned}(4.56 \times 10^{-3}) \times (7.65 \times 10^6) &= 34.88 \times 10^3 \\ &= 3.488 \times 10^4\end{aligned}$$

When dividing two numbers in scientific notation, divide the decimal parts of the numbers and subtract the powers of 10:

$$\frac{A \times 10^a}{B \times 10^b} = \frac{A}{B} \times 10^{a-b}$$

An example is

$$\begin{aligned}\frac{4.31 \times 10^5}{9.87 \times 10^{-8}} &= \frac{4.31}{9.87} \times 10^{5-(-8)} = 0.437 \times 10^{13} \\ &= 4.37 \times 10^{12}\end{aligned}$$

Before adding and subtracting numbers in scientific notation, we rewrite the numbers as decimal numbers multiplied by the same power of 10:

$$\begin{aligned}1.00 \times 10^3 + 2.00 \times 10^2 &= 1.00 \times 10^3 + 0.200 \times 10^3 \\ &= 1.20 \times 10^3\end{aligned}$$

When raising a number in scientific notation to a particular power, raise the decimal part of the number to the power and multiply the power of 10 by the power:

$$(A \times 10^a)^b = A^b \times 10^{a \times b}$$

For example, 2.88×10^4 raised to the third power is

$$\begin{aligned}(2.88 \times 10^4)^3 &= 2.88^3 \times (10^4)^3 = 2.88^3 \times 10^{3 \times 4} \\ &= 23.9 \times 10^{12} = 2.39 \times 10^{13}\end{aligned}$$

The rule follows from the fact that

$$(10^4)^3 = 10^4 \times 10^4 \times 10^4 = 10^{4+4+4} = 10^{3 \times 4}$$

The **common logarithm** of a number x, denoted log x, is the power to which 10 must be raised to equal x. Thus, the logarithm of 100 is 2, written log 100 = 2, because $10^2 = 100$. The logarithm of 1.5×10^2 is 2.18 because

$$10^{2.18} = 10^{0.18+2} = 10^{0.18} \times 10^2 = 1.5 \times 10^2$$

The number to the left of the decimal point in the logarithm (the 2 in $\log(1.5 \times 10^2) = 2.18$) is called the **characteristic** of the logarithm: it is the power of 10 in the original number (the power 2 in 1.5×10^2). The decimal fraction (the numbers to the right of the decimal point; such as 0.18 in our example) is called the **mantissa** (from the Latin word for "makeweight"). It is the logarithm of the decimal number written with one nonzero digit to the left of the decimal point (the 1.5 in the example).

The distinction between the characteristic and the mantissa is important when we have to decide how many significant figures to retain in a calculation that includes logarithms (as in the calculation of pH). Just as the power of 10 in a

decimal number indicates only the location of the decimal point and plays no role in the determination of significant figures, so the characteristic of a logarithm is not included in the count of significant figures in a logarithm (see Appendix 1C). The number of significant figures in the mantissa is equal to the number of significant figures in the decimal number.

The **common antilogarithm** of a number x is the number that has x as its common logarithm. In practice, the common antilogarithm of x is simply another name for 10^x, and so the common antilogarithm of 2 is $10^2 = 100$ and that of 2.18 is

$$10^{2.18} = 10^{0.18+2} = 10^{0.18} \times 10^2 = 1.5 \times 10^2$$

The logarithm of a number greater than 1 is positive, and the logarithm of a number less than 1 (but greater than 0) is negative:

If $x > 1$, $\log x > 0$

If $x = 1$, $\log x = 0$

If $x < 1$, $\log x < 0$

Logarithms are not defined either for 0 or for negative numbers.

The **natural logarithm** of a number x, denoted $\ln x$, is the power to which the number e = 2.718. . . must be raised to equal x. Thus, $\ln 10.0 = 2.303$, signifying that $e^{2.303} = 10.0$. The value of e may seem a peculiar choice, but it occurs naturally in a number of mathematical expressions, and its use simplifies many formulas. Common and natural logarithms are related by the expression

$$\ln x = \ln 10 \times \log x$$

In practice, a convenient approximation is

$$\ln x \approx 2.303 \times \log x$$

The **natural antilogarithm** of x is normally called the **exponential** of e; it is the value of e raised to the power x. Thus, the natural antilogarithm of 2.303 is $e^{2.303} = 10.0$.

The following relations between logarithms are useful. Written here mainly for common logarithms, they also apply to natural logarithms.

Relation	Example
$\log 10^x = x$	$\log 10^{-7} = -7$
$\ln e^x = x$	$\ln e^{-kt} = -kt$
$\log x + \log y = \log xy$	$\log [Ag^+] + \log [Cl^-] = \log [Ag^+][Cl^-]$
$\log x - \log y = \log (x/y)$	$\log A_0 - \log A = \log (A_0/A)$
$x \log y = \log y^x$	$2 \log [H^+] = \log ([H^+]^2)$
$\log(1/x) = -\log x$	$\log (1/[H^+]) = -\log [H^+]$

Logarithms are useful for solving expressions of the form

$$a^x = b$$

for the unknown x. (This type of calculation can arise in the study of chemical kinetics to determine the order of a reaction.) We take logarithms of both sides

$$\log a^x = \log b$$

and, from a relation given in the preceding table, we write the expression as

$$x \log a = \log b$$

Therefore,

$$x = \frac{\log b}{\log a}$$

1E EQUATIONS AND GRAPHS

A **quadratic equation** is an equation of the form

$$ax^2 + bx + c = 0$$

The two **roots** of the equation (the solutions) are given by the expression

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

The roots can also be determined graphically (by using a graphing calculator, for instance) by noting where the graph of $y(x) = ax^2 + bx + c$ against x passes through $y = 0$ (Fig. 1). When a quadratic equation arises in connection with a chemical calculation, we accept only the root that leads to a physically plausible result. For example, if x is a concentration, then it must be a positive number, and a negative root can be ignored.

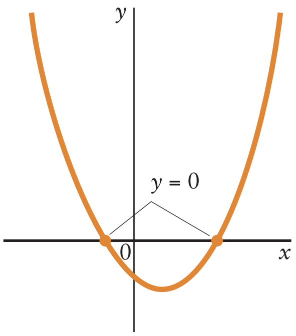

FIGURE 1 A graph of a function of the form $y(x) = ax^2 + bx + c$ passes through $y = 0$ at two points, which are the two roots of the quadratic equation $ax^2 + bx + c = 0$.

A calculation may result in a cubic equation:

$$ax^3 + bx^2 + cx + d = 0$$

Cubic equations are often very tedious to solve exactly, and so it is better to use mathematical software, a graphing calculator, or a plotter, such as the one on the Web site for this book, and to identify the locations where the graph of $y(x)$ against x passes through $y = 0$ (Fig. 2).

Experimental data can often be analyzed most effectively from a graph. In many cases, the best procedure is to find a way of plotting the data as a straight line. It is easier to tell whether the data in fact fall on the line, whereas small deviations from a curve are harder to detect. Moreover, it is also easy to calculate the slope of a straight line, to **extrapolate** (extend) a straight line beyond the range of the data, and to **interpolate** between the data points (that is, find a value between two measured values).

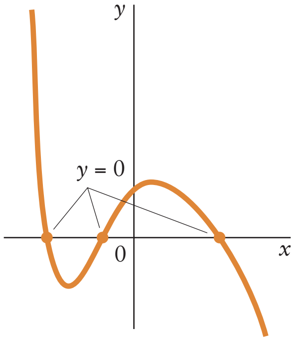

FIGURE 2 A graph of a function of the form $y(x) = ax^3 + bx^2 + cx + d$ passes through $y = 0$ at three points, which are the three roots of the cubic equation $ax^3 + bx^2 + cx + d = 0$.

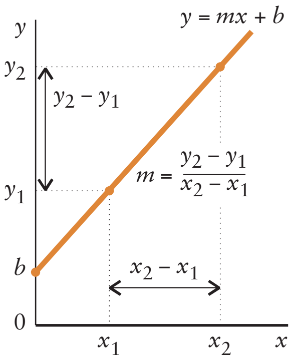

FIGURE 3 The straight line $y(x) = mx + b$; its intercept with the vertical axis at $x = 0$ is b and its slope is m.

The formula of a straight-line graph of y (the vertical axis) plotted against x (the horizontal axis) is

$$y = mx + b$$

Here b is the **intercept** of the line with the y-axis (Fig. 3), the value of y when $x = 0$. The **slope** of the graph, its gradient, is m. The slope can be calculated by choosing two points, x_1 and x_2, and their corresponding values on the y-axis, y_1 and y_2, and substituting the values into the formula

$$m = \frac{y_2 - y_1}{x_2 - x_1}$$

Because b is the intercept and m is the slope, the equation of the straight line is equivalent to

$$y = (\text{slope} \times x) + \text{intercept}$$

Many of the equations that we meet in the text can be rearranged to give a straight-line graph when plotted as shown in the following table.

Application	y	$=$ slope $\times$ x	$+$ intercept
temperature scale conversions	temp./°C	$= 1 \times T/\text{K}$	-273.15
	temp./°F	$= \frac{9}{5} \times$ temp./°C	$+32$
ideal gas law	P	$= nRT \times (1/V)$	
first-order integrated rate law	ln[A]	$= -k \times t$	$+\ln [\text{A}]_0$
second-order integrated rate law	1/[A]	$= k \times t$	$+1/[\text{A}]_0$
Arrhenius equation	$\ln k$	$= (-E_a/R) \times (1/T)$	$+\ln A$

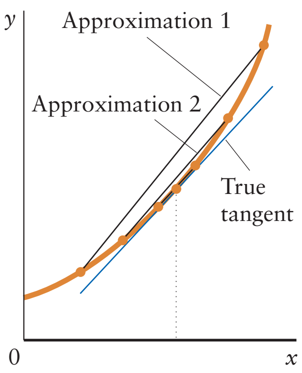

FIGURE 4 Successive approximations to the true tangent are obtained as the two points defining the straight line come closer together and finally coincide.

The slope of a straight line is the same at all points. On a curve, however, the slope changes from point to point. The slope at a specified point is given by the slope of the line tangent to the curve at that point. The tangent can be found by a series of approximations, as shown in Fig. 4. We might start (approximation 1) by drawing a point on the curve on each side of the point of interest (corresponding to equal distances along the x-axis) and joining them by a straight line. A better approximation (approximation 2) is obtained by moving the points an equal distance closer to the point of interest and drawing a new line. The exact tangent is obtained when the two points virtually coincide with the point of interest. Its slope is then equal to the slope of the curve at the point of interest. This technique can be used to measure the rate of a chemical reaction at a specified time.

1F CALCULUS

Differential calculus is the part of mathematics that deals with the slopes of curves and with infinitesimal quantities. Suppose we are studying a function $y(x)$. As explained in Appendix 1E, the slope of its graph at a point can be calculated by considering the straight line joining two points x and $x + \delta x$, where δx is small. The slope of this line is

$$\text{Slope} = \frac{y(x + \delta x) - y(x)}{\delta x}$$

In differential calculus, the slope of the curve is found by letting the separation of the points become infinitesimally small. The **first derivative** of the function y with respect to x is then defined as

$$\frac{dy}{dx} = \lim_{\delta x:\ 0} \frac{y(x + \delta x) - y(x)}{\delta x}$$

where "lim" means the limit of whatever follows—in this case, the value of the expression as δx is allowed to become zero. For example, if $y(x) = x^2$,

$$\begin{aligned}\frac{dy}{dx} &= \lim_{\delta x:\ 0} \frac{(x + \delta x)^2 - x^2}{\delta x}\\ &= \lim_{\delta x:\ 0} \frac{x^2 + 2x\delta x + (\delta x)^2 - x^2}{\delta x}\\ &= \lim_{\delta x:\ 0} \frac{2x\delta x + (\delta x)^2}{\delta x} = \lim_{\delta x:\ 0} (2x + \delta x) = 2x\end{aligned}$$

Therefore, the slope of the graph of the function $y = x^2$ at any point x is $2x$. The same procedure can be applied to other functions. However, in practice, it is usually more convenient to consult tables of first derivatives that have already been worked out. A selection of common functions and their first derivatives is given here.

Function, $y(x)$	Derivative, dy/dx
x^n	nx^{n-1}
$\ln x$	$1/x$
e^{ax}	ae^{ax}
$\sin ax$	$a \cos ax$
$\cos ax$	$-a \sin ax$

The **second derivative** of a function, denoted d^2y/dx^2, is defined like the first derivative but is applied to the function that has been obtained by taking the first derivative. For example, the second derivative of the function x^2 is the derivative of the function $2x$, which is the constant 2. Likewise,

the second derivative of sin ax is $-a^2$ sin ax. The second derivative is an indication of the curvature of the function. Where d^2y/dx^2 is positive, the graph has a ∪ shape; where it is negative, the graph has a ∩ shape. The greater the magnitude of d^2y/dx^2, the sharper the curvature of the graph.

Integral calculus provides a way to determine the original function, given its first derivative. Thus, if we know that the first derivative is $2x$, then the integral calculus allows us to deduce that the function itself is $y = x^2 + \text{constant}$. The constant is included because when we differentiate $x^2 + \text{constant}$ we get $2x$ regardless of the value of the constant. Formally, we write

$$\int (2x)\,dx = x^2 + \text{constant}$$

It follows that the functions in the left-hand column of the preceding table are the integrals (to within a constant) of the functions in the right-hand column. More formally, they are the **indefinite integrals** of the function ("indefinite" on account of the presence of the unknown constant), in contrast with the "definite" integrals described next. Tables of indefinite integrals may be consulted for more complex examples, and mathematical software or a graphing calculator can be used to evaluate them.

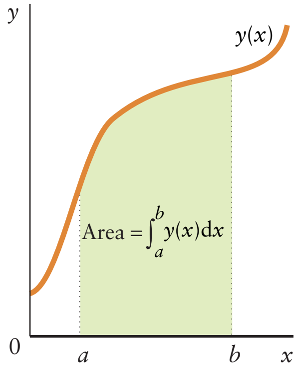

FIGURE 5 The definite integral of the function $y(x)$ between $x = a$ and $x = b$ is equal to the area bounded by the curve, the x-axis, and the two vertical lines through a and b.

An integral has a further important interpretation: the integral of a function evaluated between two points is the *area* beneath the graph of the function between the two points (Fig. 5). For example, the area beneath the curve $y(x) = \sin x$ between $x = 0$ and $x = \pi$ is

$$\begin{aligned}\text{Area} &= \int_0^{\pi} \sin x\,dx = (-\cos x + \text{constant})\Big|_0^{\pi} \\ &= \Big(-\overbrace{\cos \pi}^{-1} + \text{constant}\Big) - \Big(-\overbrace{\cos 0}^{1} + \text{constant}\Big) \\ &= 1 + 1 = 2\end{aligned}$$

An integral with limits attached, as in this example, is called a **definite integral** (because the unknown constant has canceled).

*The entropies of individual ions in solution are determined by setting the entropy of H^+ in water equal to 0 and then defining the entropies of all other ions relative to this value; hence a negative entropy is one that is lower than the entropy of H^+ in water. All *absolute* entropies are positive, and no sign need be given; all entropies of ions are relative to that of H^+ and are listed here with a sign (either + or −).

Organic Compounds

Substance	Molar mass, M (g·mol^{-1})	Enthalpy of combustion, $\Delta H_c°$ (kJ·mol^{-1})	Enthalpy of formation, $\Delta H_f°$ (kJ·mol^{-1})	Gibbs free energy of formation, $\Delta G_f°$ (kJ·mol^{-1})	Molar heat capacity, $C_{P,m}$ (J·K^{-1}·mol^{-1})	Molar entropy, $S_m°$ (J·K^{-1}·mol^{-1})

2D THE ELEMENTS

Element	Symbol	Atomic number	Molar mass* ($g \cdot mol^{-1}$)	Normal state†	Density ($g \cdot cm^{-3}$)	Melting point (°C)
actinium (Greek *aktis*, ray)	Ac	89	(227)	s, m	10.07	1230
aluminum (from alum, salts of the form $KAl(SO_4)_2 \cdot 12H_2O$)	Al	13	26.98	s, m	2.70	660
americium (the Americas)	Am	95	(243)	s, m	13.67	990
antimony (probably a corruption of an old Arabic word; Latin *stibium*)	Sb	51	121.76	s, md	6.69	631
argon (Greek *argos*, inactive)	Ar	18	39.95	g, nm	1.66‡	−189
arsenic (Greek *arsenikos*, male)	As	33	74.92	s, md	5.78	613§
astatine (Greek *astatos*, unstable)	At	85	(210)	s, nm	—	300
barium (Greek *barys*, heavy)	Ba	56	137.33	s, m	3.59	710
berkelium (Berkeley, California)	Bk	97	(247)	s, m	14.79	986
beryllium (from the mineral beryl, $Be_3Al_2SiO_{18}$)	Be	4	9.01	s, m	1.85	1285
bismuth (German *weisse Masse*, white mass)	Bi	83	208.98	s, m	8.90	271
bohrium (Niels Bohr)	Bh	107	(264)	—	—	—
boron (Arabic *buraq*, borax, $Na_2B_4O_7 \cdot 10H_2O$; *bor*(ax) + (carb)*on*	B	5	10.81	s, md	2.47	2300
bromine (Greek *bromos*, stench)	Br	35	79.90	l, nm	3.12	−7
cadmium (Greek *Cadmus*, founder of Thebes)	Cd	48	112.41	s, m	8.65	321
calcium (Latin *calx*, lime)	Ca	20	40.08	s, m	1.53	840
californium (California)	Cf	98	(251)	s, m	—	—
carbon (Latin *carbo*, coal or charcoal)	C	6	12.01	s, nm	2.27	3700§
cerium (the asteroid Ceres, discovered 2 days earlier)	Ce	58	140.12	s, m	6.71	800
cesium (Latin *caesius*, sky blue)	Cs	55	132.91	s, m	1.87	28
chlorine (Greek *chloros*, yellowish green)	Cl	17	35.45	g, nm	1.66‡	−101
chromium (Greek *chroma*, color)	Cr	24	52.00	s, m	7.19	1860
cobalt (German *Kobold*, evil spirit; Greek *kobalos*, goblin)	Co	27	58.93	s, m	8.80	1494

*Parentheses around molar mass indicate the most stable isotope of a radioactive element.

†The normal state is the state of the element at normal temperature and pressure (20°C and 1 atm). s denotes solid, l, liquid, and g, gas; m denotes metal, nm, nonmetal, and md, metalloid.

‡The density quoted is for the liquid.

§The solid sublimes.

||Charge in parentheses.

#Atomic and ionic radii are estimated.

2E THE TOP 23 CHEMICALS BY INDUSTRIAL PRODUCTION IN THE UNITED STATES IN 2008

Production data are compiled annually by the American Chemical Society and published in *Chemical and Engineering News*. This table is based on the information about production in 2008 that was published in the July 6, 2009, issue. Water, sodium chloride, and steel traditionally are not included and would outrank the rest if they were. Hydrogen is heavily used but almost always "on site" as soon as it has been prepared.

Rank	Name	Annual production (10^9 kg)	Comment on source
1	sulfuric acid	32.4	contact process
2	ethene (ethylene)	22.6	thermal cracking of petroleum
3	polyethylene	16.0	polymerization of ethene
4	propene (propylene)	14.8	thermal cracking of petroleum
5	chlorine	9.6	electrolysis
6	ammonia	9.5	Haber process
7	phosphoric acid	9.2	from phosphate rocks
8	dichloroethane (ethylene dichoride)	9.0	chlorination of ethene
9	diammonium hydrogen phosphate	8.0	processing of phosphate rocks
10	polypropylene	7.6	polymerization of propylene
11	nitric acid	7.5	Ostwald process
12	sodium hydroxide	7.3	electrolysis of brine
13	ammonium nitrate	7.3	ammonia + nitric acid
14	polyvinyl chloride and copolymers	5.8	polymerization of vinyl chloride
15	urea	5.3	ammonia + carbon dioxide
16	ammonium dihydrogen phosphate	5.0	processing of phosphate rocks
17	ethylbenzene	4.1	Friedel–Crafts alkylation of benzene
18	styrene	4.1	dehydration of ethylbenzene
19	hydrogen chloride	3.8	by-product of hydrocarbon chlorination
20	cumene (isopropylbenzene)	3.4	alkylation of benzene
21	ethylene oxide	2.9	addition of O_2 to ethene
22	ammonium sulfate	2.5	ammonia + sulfuric acid
23	polystyrene	2.4	polymerization of styrene

APPENDIX 3: Nomenclature

3A THE NOMENCLATURE OF POLYATOMIC IONS

Charge number	Chemical formula	Name	Oxidation number of central element	Charge number	Chemical formula	Name	Oxidation number of central element
+2	Hg_2^{2+}	mercury(I)	+1		O_3^-	ozonide	$-\frac{1}{3}$
	UO_2^{2+}	uranyl	+6		OH^-	hydroxide	−2(O)
	VO^{2+}	vanadyl	+4		SCN^-	thiocyanate	—
+1	NH_4^+	ammonium	−3	−2	C_2^{2-}	carbide	−1
	PH_4^+	phosphonium	−3			(acetylide)	
−1	$CH_3CO_2^-$	acetate	0(C)		CO_3^{2-}	carbonate	+4
		(ethanoate)			$C_2O_4^{2-}$	oxalate	+3
	HCO_2^-	formate	+2(C)		CrO_4^{2-}	chromate	+6
		(methanoate)			$Cr_2O_7^{2-}$	dichromate	+6
	CN^-	cyanide	+2(C), −3(N)		O_2^{2-}	peroxide	−1
	ClO_4^-	perchlorate*	+7		S_2^{2-}	disulfide	−1
	ClO_3^-	chlorate*	+5		SiO_3^{2-}	metasilicate	+4
	ClO_2^-	chlorite*	+3		SO_4^{2-}	sulfate	+6
	ClO^-	hypochlorite*	+1(Cl)		SO_3^{2-}	sulfite	+4
	MnO_4^-	permanganate	+7		$S_2O_3^{2-}$	thiosulfate	+2
	NO_3^-	nitrate	+5	−3	AsO_4^{3-}	arsenate	+5
	NO_2^-	nitrite	+3		BO_3^{3-}	borate	+3
	N_3^-	azide	$-\frac{1}{3}$		PO_4^{3-}	phosphate	+5

*These names are representative of the halogen oxoanions.

When a hydrogen ion bonds to a −2 or −3 anion, add "hydrogen" before the name of the anion. For example, HSO_3^- is hydrogen sulfite (or hydrogensulfite). If two hydrogen ions bond to a −3 anion, add "dihydrogen" before the name of the anion. For example, $H_2PO_4^-$ is dihydrogen phosphate (or dihydrogenphosphate).

Oxoacids and Oxoanions

The names of oxoanions and their parent acids can be determined by noting the oxidation number of the central atom and then referring to the table on the right. For example, the nitrogen in $N_2O_2^{2-}$ has an oxidation number of +1; because nitrogen belongs to Group 15/V, the ion is a hyponitrite ion.

Group number					
14/IV	**15/V**	**16/VI**	**17/VII**	**Oxoanion**	**Oxoacid**
—	—	–	+7	per . . . ate	per . . . ic acid
+4	+5	+6	+5	. . . ate	. . . ic acid
—	+3	+4	+3	. . . ite	. . . ous acid
—	+1	+2	+1	hypo . . . ite	hypo . . . ous acid

3B COMMON NAMES OF CHEMICALS

Many chemicals are often referred to by their common names, sometimes as a result of their use over hundreds of years and sometimes because they appear on the labels of consumer products, such as detergents, beverages, and antacids. The following names are just a few that have found their way into the language of everyday life.

Common name	Formula	Chemical name
baking soda	$NaHCO_3$	sodium hydrogen carbonate (sodium bicarbonate)
bleach, laundry	$NaClO$	sodium hypochlorite
borax	$Na_2B_4O_7 \cdot 10H_2O$	sodium tetraborate decahydrate
brimstone	S_8	sulfur
calamine	$ZnCO_3$	zinc carbonate
chalk	$CaCO_3$	calcium carbonate
Epsom salts	$MgSO_4 \cdot 7H_2O$	magnesium sulfate heptahydrate
fool's gold	FeS_2	iron(II) disulfide
gypsum	$CaSO_4 \cdot 2H_2O$	calcium sulfate dihydrate
lime (quicklime)	CaO	calcium oxide
lime (slaked lime)	$Ca(OH)_2$	calcium hydroxide
limestone	$CaCO_3$	calcium carbonate
lye, caustic soda	$NaOH$	sodium hydroxide
marble	$CaCO_3$	calcium carbonate
milk of magnesia	$Mg(OH)_2$	magnesium hydroxide
plaster of Paris	$CaSO_4 \cdot \frac{1}{2}H_2O$	calcium sulfate hemihydrate
potash*	K_2CO_3	potassium carbonate
quartz	SiO_2	silcon dioxide
table salt	$NaCl$	sodium chloride
vinegar	CH_3COOH	acetic acid (ethanoic acid)
washing soda	$Na_2CO_3 \cdot 10H_2O$	sodium carbonate decahydrate

*Potash also refers collectively to K_2CO_3, KOH, K_2SO_4, KCl, and KNO_3.

3C NAMES OF SOME COMMON CATIONS WITH VARIABLE CHARGE NUMBERS

Modern nomenclature includes the oxidation number of elements with variable oxidation states in the names of their compounds, as in cobalt(II) chloride. However, the traditional nomenclature, in which the suffixes *-ous* and *-ic* are used, is still encountered. The table on the right translates from one system into the other for some common elements.

Element	Cation	Old-style name	Modern name
cobalt	Co^{2+}	cobaltous	cobalt(II)
	Co^{3+}	cobaltic	cobalt(III)
copper	Cu^{+}	cuprous	copper(I)
	Cu^{2+}	cupric	copper(II)
iron	Fe^{2+}	ferrous	iron(II)
	Fe^{3+}	ferric	iron(III)
lead	Pb^{2+}	plumbous	lead(II)
	Pb^{4+}	plumbic	lead(IV)
manganese	Mn^{2+}	manganous	manganese(II)
	Mn^{3+}	manganic	manganese(III)
mercury	Hg_2^{2+}	mercurous	mercury(I)
	Hg^{2+}	mercuric	mercury(II)
tin	Sn^{2+}	stannous	tin(II)
	Sn^{4+}	stannic	tin(IV)

GLOSSARY

***ab initio* method** The calculation of molecular structure by solving the *Schrödinger equation* numerically. Compare with *semiempirical method*.

absolute zero ($T = 0$; that is, 0 on the *Kelvin scale*) The lowest possible temperature (−273.15°C).

absorb To accept one substance into and throughout the bulk of another substance. Compare with *adsorb*.

absorbance (A) A measure of the extent of absorption of radiation by a sample: $A = \log(I_0/I)$.

absorbed dose (of radiation) The energy deposited in a given mass of sample when it is exposed to radiation (particularly but not exclusively nuclear radiation). Absorbed dose is measured in *rad* or *gray*.

absorption spectrum The wavelength dependence of the absorption of a sample, determined by measuring the extent to which the sample absorbs electromagnetic radiation as the wavelength is varied over a range.

abundance (of an isotope) The percentage (in terms of the numbers of atoms) of the isotope present in a sample of the element. See also *natural abundance*.

acceleration The rate of change of velocity (either its direction or its magnitude).

acceleration of free fall (g) The acceleration experienced by a body owing to the gravitational field at the surface of the Earth.

accuracy Freedom from systematic error. Compare with *precision*.

accurate measurement A measurement that has small systematic error and gives a result close to the accepted value of the property.

achiral Not chiral: identical with its mirror image. See also *chiral*.

acid See *Arrhenius acid*; *Brønsted acid*; *Lewis acid*. Used alone, "acid" normally means a Brønsted acid.

acid anhydride A compound that forms an oxoacid when it reacts with water. See also *formal anhydride*. *Example*: SO_3, the anhydride of sulfuric acid.

acid–base indicator See *indicator*.

acid–base titration See *titration*.

acid buffer See *buffer*.

acidic hydrogen atom A hydrogen atom (more exactly, the proton of that hydrogen atom) that can be donated to a base.

acidic ion An ion that acts as a Brønsted acid. *Examples*: NH_4^+; $[Al(H_2O)_6]^{3+}$.

acidic oxide An oxide that reacts with water to give an acid; the oxides of nonmetallic elements generally are acidic oxides. *Examples*: CO_2; SO_3.

acidic solution A solution with pH < 7.

acid ionization (dissociation) constant (K_a) See *acidity constant*.

acidity The strength of the tendency to donate a proton.

acidity constant (K_a) The equilibrium constant for proton transfer to water; for an acid HA, $K_a = [H_3O^+][A^-]/[HA]$ at equilibrium.

actinide Former (and still very common) term for *actinoid*.

actinoid A member of the second row of the f-block (thorium through nobelium).

activated complex An unstable combination of reactant molecules that can either go on to form products or fall apart into the unchanged reactants.

activated complex theory See *transition state theory*.

activation energy (E_a) (1) The minimum energy needed for reaction. (2) The height of the activation barrier. (3) An empirical parameter that describes the temperature dependence of the rate constant of a reaction.

activity (1) In thermodynamics, a_J, the effective concentration or pressure of a species J expressed as the partial pressure or concentration of the species relative to its standard value. (2) In radioactivity, the number of nuclear disintegrations per second.

activity coefficient (γ_J) The proportionality factor between the activity of a species and its molar concentration or partial pressure (divided by its standard value). *Example:* for a solute J, $a_J = \gamma_J[J]/c°$.

addition polymerization The polymerization, usually of alkenes, by an addition reaction propagated by radical or ionic intermediates.

addition reaction A chemical reaction in which atoms or groups bond to two atoms joined by a multiple bond. The product of the reaction is a single molecule that contains all the reactant atoms. *Example:* $CH_3CH{=}CH_2 + HBr \rightarrow CH_3CH_2CH_2Br$.

adhesion Binding to a surface.

adhesive forces Forces that bind a substance to a surface.

adiabatic Not permitting or accompanied by the passage of energy as heat. *Example:* adiabatic wall.

adsorb To bind a substance to a surface; the surface *adsorbs* the substance. Distinguish from *absorb*.

aerosol A fine mist of solid particles or droplets of liquid suspended in a gas.

alcohol An organic molecule containing an —OH group attached to a carbon atom that is not part of a carbonyl group or an aromatic ring. Alcohols are classified as *primary, secondary,* and *tertiary* according to the number of carbon atoms attached to the C—OH carbon atom. *Examples:* CH_3CH_2OH (primary); $(CH_3)_2CHOH$ (secondary); $(CH_3)_3COH$ (tertiary).

aldehyde An organic compound containing the —CHO group. *Examples:* CH_3CHO, ethanal (acetaldehyde); C_6H_5CHO, benzaldehyde.

aliphatic hydrocarbon A hydrocarbon that does not have benzene rings in its structure.

alkali An aqueous solution of a strong base. *Example:* aqueous NaOH.
alkali metal A member of Group 1 of the periodic table (the lithium family).
alkaline earth metal Calcium, strontium, and barium; more informally, a member of Group 2 of the periodic table (the beryllium family).
alkaline solution An aqueous solution with pH > 7.
alkane (1) A hydrocarbon with no carbon–carbon multiple bonds. (2) A saturated hydrocarbon. (3) A member of a series of hydrocarbons derived from methane by the repetitive insertion of $—CH_2—$ groups; alkanes have the molecular formula C_nH_{2n+2}. *Examples:* CH_4; CH_3CH_3; $CH_3(CH_2)_6CH_3$.
alkene (1) A hydrocarbon with at least one carbon–carbon double bond. (2) A member of a series of hydrocarbons derived from ethene by the repetitive insertion of $—CH_2—$ groups; alkenes with one double bond have the molecular formula C_nH_{2n}. *Examples:* $CH_2{=}CH_2$; $CH_3CH{=}CH_2$; $CH_3CH{=}CHCH_2CH_3$.
alkyne (1) A hydrocarbon with at least one carbon–carbon triple bond. (2) A member of a series of hydrocarbons derived from ethyne by the repetitive insertion of $—CH_2—$ groups; alkynes with one triple bond have the molecular formula C_nH_{2n-2}. *Examples:* $CH{\equiv}CH$; $CH_3C{\equiv}CCH_3$.
allotropes Alternative forms of an element that differ in the way in which the atoms are linked. *Examples:* O_2 and O_3; white and gray tin.
alloy A mixture of two or more metals formed by melting, mixing, and then cooling. A *substitutional alloy* is an alloy in which atoms of one metal are substituted for atoms of another metal. An *interstitial alloy* is an alloy in which atoms of one metal lie in the gaps in the lattice formed by atoms of another metal. A *homogeneous alloy* is an alloy in which the atoms of the elements are distributed uniformly. A *heterogeneous alloy* is an alloy that consists of (micro)crystalline phases with different compositions.
alpha (α) helix One type of secondary structure adopted by a polypeptide chain, in the form of a right-handed helix.
alpha (α) particle Positively charged, subatomic particle emitted from some radioactive nuclei; nucleus of a helium atom ($^4_2He^{2+}$).
alternating copolymer See *copolymer.*
ambidentate ligand A ligand that can coordinate to a metal atom by using atoms of different elements. *Example:* SCN^-, which can coordinate through S or N.
amide An organic compound formed by the reaction of an amine and a carboxylic acid in which the acidic $—OH$ group has been replaced by an amino group or a substituted amino group. An amide contains the group $—CONR_2$. *Example:* CH_3CONH_2, acetamide.
amine A compound derived from ammonia by replacing various numbers of H atoms with organic groups; the number of hydrogen atoms replaced determines the classification as *primary, secondary,* or *tertiary. Examples:* CH_3NH_2 (primary); $(CH_3)_2NH$ (secondary); $(CH_3)_3N$ (tertiary). See also *quaternary ammonium ion*.
amino acid A carboxylic acid that also contains an amino group. The *essential amino acids* are amino acids that must be ingested as a part of the diet. *Example:* NH_2CH_2COOH, glycine. See Table 19.4.
amino group The functional group $—NH_2$ characteristic of *amines.*
amorphous solid A solid in which the atoms, ions, or molecules lie in a random jumble with no long-range order. *Examples:* glass; butter. Compare with *crystalline solid*.
amount of substance (n) The number of entities in a sample divided by Avogadro's constant. Also referred to as *chemical amount*. See *mole.*
ampere (A) The SI unit of electric current. See also Appendix 1B.
amphiprotic Having the ability both to donate and to accept protons. See *amphoteric*. *Examples:* H_2O; HCO_3^-.
amphoteric Having the ability to react with both acids and bases. See *amphiprotic*. *Examples:* Al; Al_2O_3.
amplitude The height of a mathematical function above 0. On a graph depicting a wave, the height of the wave above the center line.
analysis See *chemical analysis.*
analyte The solution of unknown concentration in a titration. Normally, the analyte is in the flask, not the buret.
analytical chemistry The study and application of techniques for identifying substances and measuring their amounts.
angular wavefunction ($Y(\theta,\phi)$) The angular part of a wavefunction, particularly the angular component of the wavefunctions of the hydrogen atom; the probability amplitude of an electron as a function of orientation around the nucleus.
anhydride See *acid anhydride*.
anhydrous Lacking water. *Example:* $CuSO_4$, the anhydrous form of copper(II) sulfate. Compare with *hydrate.*
anion A negatively charged ion. *Examples:* F^-; SO_4^{2-}.
anisotropic Depending on orientation.
anode The electrode at which oxidation takes place.
antibonding orbital A molecular orbital that, when occupied, contributes to an overall raising of the energy of a molecule.
antiferromagnetic material A substance in which electron spins on neighboring atoms are locked into an antiparallel arrangement over large regions. *Example:* manganese.
antilogarithm If the logarithm to the base B is x, then the antilogarithm of x is B^x. The *common antilogarithm* of x is 10^x. The *natural antilogarithm* of x is the exponential e^x.
antioxidant A substance that reacts with radicals and so prevents the oxidation of another substance.
antiparticle A particle with the same mass as a subatomic particle but with opposite charge. *Example:* positron, the antiparticle of an electron.
applied research Investigations directed toward the solution of real-world problems. See also *basic research*.
aqueous solution A solution in which the solvent is water.
arene An aromatic hydrocarbon.
aromatic compound An organic compound that includes a benzene ring as part of its structure. *Examples:* C_6H_6 (benzene); C_6H_5Cl (chlorobenzene); $C_{10}H_8$ (naphthalene).

aromatic hydrocarbon See *aromatic compound* (the more general term).

Arrhenius acid A compound that contains hydrogen and releases hydrogen ions (H^+) in water. *Examples:* HCl; CH_3COOH; but not CH_4.

Arrhenius base A compound that produces hydroxide ions (OH^-) in water. *Examples:* NaOH; NH_3; but not Na, because it is not a compound.

Arrhenius behavior A reaction shows Arrhenius behavior if a plot of ln k against $1/T$ is a straight line. See *Arrhenius equation*.

Arrhenius equation The equation $\ln k = \ln A - E_a/RT$ for the commonly observed temperature dependence of a rate constant k. An *Arrhenius plot* is a graph of ln k against $1/T$.

Arrhenius parameters The *pre-exponential factor A* (also called the *frequency factor*) and the *activation energy* E_a. See also *Arrhenius equation*.

aryl group An aromatic group. *Example:* $-C_6H_5$, phenyl.

atmosphere (1) The layer of gases surrounding a planet (specifically, the air for planet Earth). (2) A unit of pressure ($1\ atm = 1.013\ 25 \times 10^5$ Pa exactly).

atom (1) The smallest particle of an element that has the chemical properties of that element. (2) An electrically neutral species consisting of a nucleus and its surrounding electrons.

atomic hypothesis The proposal advanced by John Dalton that matter is composed of atoms.

atomic mass constant (m_u, formerly amu) One-twelfth the mass of one atom of carbon-12.

atomic nucleus See *nucleus*.

atomic number (Z) The number of protons in the nucleus of an atom; this number determines the identity of the element and the number of electrons in the neutral atom.

atomic orbital A region of space in which there is a high probability of finding an electron in an atom. An *s-orbital* is a spherical region; a *p-orbital* has two lobes, on opposite sides of the nucleus; a *d-orbital* typically has four lobes, with the nucleus at the center; an *f-orbital* has a more complicated arrangement of lobes.

atomic radius Half the distance between the centers of neighboring atoms in a solid or a homonuclear molecule.

atomic structure The arrangement of electrons around the nucleus of an atom.

atomic weight The numerical value of the *molar mass* of an element.

***Aufbau* principle** See *building-up principle*.

autoionization See *autoprotolysis*.

autoprotolysis A reaction in which a proton is transferred between two molecules of the same substance. The products are the conjugate acid and conjugate base of the substance. *Example:* $2\,H_2O(l) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$.

autoprotolysis constant The equilibrium constant for an autoprotolysis reaction. *Example:* for water, K_w, with $K_w = [H_3O^+][OH^-]$.

average bond enthalpy ($\Delta H_B(A{-}B)$) See *mean bond enthalpy*.

average reaction rate The reaction rate calculated by measuring the change in concentration of a reactant or product over a finite time interval (and hence an average of the changing rate within that interval). See also *unique average reaction rate*.

Avogadro's constant The number of objects per mole of objects ($N_A = 6.022\ 14 \times 10^{23}\ mol^{-1}$). *Avogadro's number* is the number of objects in 1 mol of objects (that is, the dimensionless number $6.022\ 14 \times 10^{23}$).

Avogadro's principle The volume of a sample of gas at a given temperature and pressure is proportional to the amount of gas molecules in the sample: $V \propto n$.

axial bond A bond that is perpendicular to the molecular plane in a bipyramidal molecule.

axial lone pair A lone pair lying on the axis of a bipyramidal molecule.

azeotrope A mixture of liquids that boils without change of composition. A *minimum-boiling azeotrope* has a boiling point lower than that of either component; a *maximum-boiling azeotrope* has a boiling point higher than that of either component.

azimuthal quantum number (l) See *orbital angular momentum quantum number*.

background radiation The average nuclear radiation to which the Earth's inhabitants are exposed daily.

balanced equation See *chemical equation*.

ball-and-stick model A depiction of a molecule in which atoms are represented by balls and bonds are represented by sticks.

Balmer series A family of spectral lines (some of which lie in the visible region) in the spectrum of atomic hydrogen.

band gap A range of energies for which there are no orbitals in a solid. Unless stated otherwise, the band gap refers to the gap between the valence band and the conduction band.

band of stability A region of a plot of mass number against atomic number corresponding to the existence of stable nuclei.

bar A unit of pressure: $1\ bar = 10^5$ Pa.

barometer An instrument for measuring the atmospheric pressure.

base See *Arrhenius base; Brønsted base; Lewis base*. Used alone, "base" normally means a Brønsted base.

base buffer See *buffer*.

base ionization constant See *basicity constant*.

base pair Two specific nucleotides that link one complementary strand of a DNA molecule to the other by means of hydrogen bonding: adenine pairs with thymine and guanine pairs with cytosine.

base units The units of measurement in the International System (SI) in terms of which all other units are defined. *Examples: kilogram* for mass; *meter* for length; *second* for time; *kelvin* for temperature; *ampere* for electric current.

basic ion An ion that acts as a Brønsted base. *Example:* $CH_3CO_2^-$.

basicity constant (K_b) The equilibrium constant for proton transfer from water to a base; for a base B, $K_b = [BH^+][OH^-]/[B]$.

basic oxide An oxide that is a Brønsted base. The oxides of metallic elements are generally basic. *Examples:* Na_2O; MgO.

basic research Investigations aimed at discovering the reasons for phenomena and the fundamental principles of

chemistry, the synthesis of new materials, and the investigation of their properties. See also *applied research*.

basic solution A solution with $pH > 7$.

battery A collection of galvanic cells joined in series; the voltage that the battery produces is the sum of the voltages of each cell.

becquerel (Bq) The SI unit of radioactivity (one disintegration per second).

Beer's law The absorbance of electromagnetic radiation by a sample is proportional to the molar concentration of the absorbing species and the length of the sample through which the radiation passes.

beta (β) decay Nuclear decay due to *β-particle* emission.

beta (β) particle A fast electron emitted from a nucleus in a radioactive decay.

beta (β) sheet One type of planar secondary structure adopted by a polypeptide, in the form of a pleated sheet.

bimolecular reaction An elementary reaction in which two molecules, atoms, or ions come together and form a product. *Example:* $O + O_3 \longrightarrow O_2 + O_2$.

binary Consisting of two components, as in *binary mixture* and *binary* (*ionic* or *molecular*) *compound*. *Examples:* acetone and water (a binary mixture); HCl, $CaCl_2$, C_6H_6 (binary compounds; $CaCl_2$ is ionic, HCl and C_6H_6 are molecular).

bio-based material A material taken from or made from natural materials in living things.

biochemistry The study of biologically important substances, processes, and reactions.

bioenergetics The deployment and utilization of energy in living cells.

biological chemistry The application of chemical principles to biological structures and processes.

biomass The organic material of the planet produced annually by photosynthesis.

biomimetic material A material modeled after a naturally occurring material.

biradical A species with two unpaired electrons. *Example:* $\cdot CH_2CH_2CH_2\cdot$.

black body An object that absorbs and emits all frequencies of radiation without favor.

black-body radiation The electromagnetic radiation emitted by a *black body*.

block (s-block, p-block, d-block, f-block) The region of the periodic table containing elements for which, according to the building-up principle, the corresponding subshell is currently being filled.

block copolymer See *copolymer*.

body-centered cubic structure (bcc) A crystal structure with a unit cell in which a central atom lies at the center of a cube formed by eight others.

Bohr frequency condition The relation between the change in energy of an atom or molecule and the frequency of radiation emitted or absorbed: $\Delta E = h\nu$.

Bohr radius (a_0) In an early model of the hydrogen atom, the radius of the lowest energy orbit; now a specific combination of fundamental constants ($a_0 = 4\pi\varepsilon_0\hbar^2/m_e e^2 = 52.9$ pm) in the description of the wavefunctions of hydrogen.

boiling Rapid vaporization taking place throughout a liquid. See *boiling temperature*.

boiling point (b.p.) See *boiling temperature; normal boiling point*.

boiling-point constant (k_b) The constant of proportionality between the boiling-point elevation and the molality of a solute.

boiling-point elevation The increase in normal boiling point of a solvent caused by the presence of a solute (a *colligative property*).

boiling temperature (1) The temperature at which a liquid boils. (2) The temperature at which a liquid is in equilibrium with its vapor at the pressure of the surroundings; vaporization then occurs throughout the liquid, not only at the liquid's surface.

Boltzmann formula (for the entropy) The formula $S = k \ln W$, where k is *Boltzmann's constant* and W is the number of atomic arrangements that correspond to the same energy.

Boltzmann's constant (k) A fundamental constant; $k = 1.380\,66 = 10^{-23}\ J\cdot K^{-1}$. Note that $R = N_A k$.

bond A link between atoms. See also *covalent bond; double bond; ionic bond; triple bond*.

bond angle In an A—B—C molecule or part of a molecule, the angle between the B—A and B—C bonds.

bond enthalpy (ΔH_B(X—Y)) The enthalpy change accompanying the dissociation of a bond. *Example:* $H_2(g) \longrightarrow 2\ H(g)$, $\Delta H_B(H—H) = +436\ kJ\cdot mol^{-1}$.

bonding orbital A molecular orbital that, when occupied, results in an overall lowering of the energy of a molecule.

bond length The distance between the centers of two atoms joined by a bond.

bond order The number of electron pair bonds that link a specific pair of atoms.

Born–Haber cycle A closed series of reactions used to express the enthalpy of formation of an ionic solid in terms of contributions that include the lattice enthalpy.

Born interpretation The interpretation of the square of the wavefunction, ψ, of a particle as the probability density for finding the particle in a region of space.

Born–Mayer equation The formula for the minimum energy of an ionic solid.

boundary condition A constraint on the value of the wavefunction of a particle.

boundary surface The surface showing the region of space within which there is about 90% probability of finding an electron when it occupies a specific orbital in an atom or molecule.

Boyle's law At constant temperature, and for a given sample of gas, the volume is inversely proportional to the pressure: $P \propto 1/V$.

Bragg equation An equation relating the angle of diffraction of x-rays to the spacing of layers of atoms in a crystal ($\lambda = 2d \sin\theta$).

branched alkane An alkane with hydrocarbon side chains.

branching Description of a step in a chain reaction in which more than one chain carrier is formed in a propagation step. *Example:* $\cdot O\cdot + H_2 \longrightarrow \cdot OH + \cdot H$. See also *propagation*.

Bravais lattices The 14 basic patterns of unit cells from which a crystal can be built.

breeder reactor A reactor used to generate nuclear fuel by making use of neutrons that are not moderated.

Brønsted acid A proton donor (a source of hydrogen ions, H^+). *Examples:* HCl; CH_3COOH; HCO_3^-; NH_4^+.

Brønsted base A proton acceptor (a species to which hydrogen ions, H^+, can bond). *Examples:* OH^-; Cl^-; $CH_3CO_2^-$; HCO_3^-; NH_3.

Brønsted–Lowry definition A definition of acids and bases in terms of the ability of molecules and ions to participate in proton transfer. See *Brønsted–Lowry theory*.

Brønsted–Lowry theory A theory of acids and bases involving proton transfer from one species to another. See also *Brønsted acid* and *Brønsted base*.

Brownian motion The ceaseless jittering motion of colloidal particles caused by the impact of solvent molecules.

buffer A solution that resists any change in pH when small amounts of acid or base are added. An *acid buffer* stabilizes solutions at pH < 7 and a *base buffer* stabilizes solutions at pH > 7. *Examples:* a solution containing CH_3COOH and $CH_3CO_2^-$ (acid buffer); a solution containing NH_3 and NH_4^+ (base buffer).

buffer capacity An indication of the amount of acid or base that can be added before a buffer loses its ability to resist the change in pH.

building-up principle The procedure for arriving at the ground-state electron configurations of atoms and molecules.

bulk matter Matter composed of large numbers of atoms. See *bulk property*.

bulk property A property that depends on the collective behavior of large numbers of atoms. *Examples:* melting point; vapor pressure; internal energy.

buret A narrow, graduated tube fitted with a stopcock, used to measure the volume of liquid delivered into another vessel.

calibration Interpretation of an observation by comparison with known information.

calorie (cal) A unit of energy. The unit is now defined in terms of the joule by 1 cal = 4.184 J exactly. The *nutritional calorie* is 1 kcal.

calorimeter An apparatus used to determine the heat released or absorbed in a process by measuring the temperature change.

candela (cd) The SI unit of luminous intensity. See also Appendix 1B.

capillary action The rise of liquids up narrow tubes.

carbohydrate A compound of general formula $C_m(H_2O)_n$, although small deviations from this general formula are often encountered. Carbohydrates include cellulose, starches, and sugars. *Examples:* $C_6H_{12}O_6$, glucose; $C_{12}H_{22}O_{11}$, sucrose.

carbonyl group A $>$CO group in an inorganic or organic compound.

carboxyl group The functional group —COOH. See *carboxylic acid*.

carboxylic acid An organic compound containing the carboxyl group, —COOH. *Examples:* CH_3COOH, acetic acid; C_6H_5COOH, benzoic acid.

carrier See *chain carrier*.

catalyst A substance that increases the rate of a reaction without being consumed in the reaction. A catalyst is *homogeneous* if it is present in the same phase as the reactants and *heterogeneous* if it is in a different phase from the reactants. *Examples:* homogeneous, $Br^-(aq)$ for the decomposition of $H_2O_2(aq)$; heterogeneous, Pt in the Ostwald process.

catenate To form chains or rings of atoms. *Examples:* O_3; S_8.

cathode The electrode at which reduction takes place.

cathodic protection Protection of a metal object by connecting it to a more strongly reducing metal.

cation A positively charged ion. *Examples:* Na^+; NH_4^+; Al^{3+}.

cell diagram A description of an electrochemical cell that corresponds to a given cell reaction. *Example:* $Zn(s)|Zn^{2+}(aq)||Cu^{2+}(aq)|Cu(s)$.

cell potential (E_{cell}) (1) The potential difference between the electrodes of an electrochemical cell when it is producing no current. (2) An indication of the tendency of a reaction in an electrochemical cell to occur spontaneously.

Celsius scale A temperature scale on which the freezing point of water is at 0 degrees and its normal boiling point is at 100 degrees. Units on this scale are degrees Celsius, °C.

ceramic (1) A solid obtained by the action of heat on clay. (2) A noncrystalline inorganic solid usually containing oxides, borides, and carbides.

cesium chloride structure A crystal structure the same as that of solid cesium chloride.

chain branching A propagation step in a chain reaction when more than one chain carrier is formed.

chain carrier An intermediate in a chain reaction.

chain reaction A reaction that is propagated when an intermediate reacts to produce another intermediate in a series of elementary reactions. *Example:* $Br\cdot + H_2 \longrightarrow HBr + H\cdot$ followed by $H\cdot + Br_2 \longrightarrow HBr + Br\cdot$.

chalcogens Oxygen, sulfur, selenium, and tellurium in Group 16/VI of the periodic table.

change of state The change of a substance from one of its physical states to another of its physical states. *Example:* melting, solid $\longrightarrow$ liquid.

characteristic (of a logarithm) The number preceding the decimal point.

charge A measure of the strength with which a particle can interact electrostatically with another particle.

charge balance The requirement that, because a solution is neutral overall, the concentration of positive charge due to cations must equal the concentration of negative charge due to anions.

charge-transfer transition A transition in which an electron is excited from the ligands of a complex to the metal atom or vice versa.

Charles's law The volume of a given sample of gas at constant pressure is directly proportional to its absolute temperature: $V \propto T$.

chelate A complex containing at least one polydentate ligand that forms a ring of atoms including the central metal atom. *Example:* $[Co(en)_3]^{3+}$.

chemical analysis The determination of the chemical composition of a sample. See also *qualitative, quantitative*.

chemical bond See *bond*.

chemical change The conversion of one or more substances into different substances.

chemical element See *element*.

chemical energy The energy available from a chemical reaction. *Example:* the energy released in the combustion of a fuel.
chemical engineering The study of industrial chemical processes.
chemical equation A statement in terms of chemical formulas summarizing the qualitative information about the chemical changes taking place in a reaction and the quantitative information that atoms are neither created nor destroyed in a chemical reaction. In a *balanced chemical equation* (commonly called a "chemical equation"), the same number of atoms of each element appears on both sides of the equation.
chemical equilibrium A dynamic equilibrium between reactants and products in a chemical reaction.
chemical formula A collection of chemical symbols and subscripts that shows the composition of a substance. See also *condensed structural formula; empirical formula; molecular formula; structural formula*.
chemical kinetics The study of the rates of chemical reactions and the steps by which they take place.
chemical nomenclature The systematic naming of compounds.
chemical plating The deposition of a metal surface on an object by making use of a chemical reduction reaction.
chemical property The ability of a substance to participate in a chemical reaction.
chemical reaction A chemical change in which one substance responds to the presence of another, to a change of temperature, or to some other influence.
chemical symbol The abbreviation of the name of an element.
chemiluminescence The emission of light by products formed in energetically excited states during a chemical reaction.
chemistry The branch of science concerned with the study of matter and the changes that matter can undergo.
chiral (molecule or complex) Not able to be superimposed on its own mirror image. *Examples:* $CH_3CH(NH_2)COOH$; CHBrClF; $[Co(en)_3]^{3+}$.
chloralkali process The production of chlorine and sodium hydroxide by the electrolysis of aqueous sodium chloride.
cholesteric phase A liquid crystal phase in which layers of parallel molecules are twisted relative to one another in such a way that the orientations of the molecules form a helical structure.
chromatogram A record of the signal from the detector (or the paper record) obtained in a chromatographic analysis of a mixture.
chromatography A separation technique that relies on the ability of different phases to adsorb substances to different extents.
cis–trans isomerization The conversion of a cis isomer into a trans isomer and vice versa. *Example: cis*-butene $\rightleftarrows$ *trans*-butene.
classical mechanics The laws of motion proposed by Isaac Newton in which particles travel in definite paths in response to forces.
clathrate A structure in which a molecule of one substance sits in a cage made up of molecules of another substance, typically water. *Example:* SO_2 in water.
Clausius–Clapeyron equation An equation that gives the quantitative dependence of the vapor pressure of a substance on the temperature.
Clausius inequality The relation $\Delta S \geq q/T$.
Claus process A process for obtaining sulfur from the H_2S in oil wells by the oxidation of H_2S with SO_2; the latter is formed by the oxidation of H_2S with oxygen.
closed shell (or subshell) A shell (or subshell) containing the maximum number of electrons allowed by the exclusion principle. *Example:* the neonlike core $1s^22s^22p^6$.
closed system See *system*.
close-packed structure A crystal structure in which atoms occupy the smallest total volume with the least empty space. *Examples:* hexagonal close packing and cubic close packing of identical spheres.
coagulation The formation of aggregates from colloidal particles.
cohesion The act or state in which the particles of a substance stick to one another.
cohesive forces The forces that bind the molecules of a substance together to form a bulk material and are responsible for condensation.
coinage metals The elements copper, silver, and gold.
colligative property A property that depends only on the relative number of solute and solvent particles present in a solution and not on the chemical identity of the solute. *Examples:* elevation of boiling point; depression of freezing point; osmosis.
collision cross section The area that a molecule presents as a target during a collision.
collision theory The theory of elementary gas-phase bimolecular reactions in which molecules are assumed to react only if they collide with a characteristic minimum kinetic energy.
colloid (or colloidal suspension) A dispersion of tiny particles with diameters between 1 nm and 1 μm in a gas, liquid, or solid. *Example:* milk.
combined gas law A combination of Boyle's law and Charles's law that allows the pressure, volume, or temperature of a sample of an ideal gas to be predicted after a change in state. $P_1V_1/n_1T_1 = P_2V_2/n_2T_2$.
combustion A reaction in which an element or compound burns in oxygen. *Example:* $CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(l)$.
combustion analysis The determination of the composition of a sample by the measurement of the masses of the products of its combustion.
common antilogarithm See *antilogarithm*.
common-ion effect Reduction of the solubility of one salt by the presence of another salt with one ion in common. *Example:* the lower solubility of AgCl in NaCl(aq) than in pure water.
common logarithm See *logarithm*.
common name An informal name for a compound that may give little or no clue to the compound's composition. *Examples:* water; aspirin; acetic acid.

competing reaction A reaction taking place at the same time as the reaction of interest and using some of the same reactants, but forming different products.
complementarity The impossibility of knowing the position of a particle with arbitrarily great precision if its linear momentum is known precisely.
complementary color The color that white light becomes when one of the colors present in it is removed.
complete ionic equation A balanced chemical equation expressed in terms of the cations and anions present in solution. *Example:* $Ag^+(aq) + NO_3^-(aq) + Na^+(aq) + Cl^-(aq) \longrightarrow AgCl(s) + NO_3^-(aq) + Na^+(aq)$.
complex (1) The combination of a Lewis acid and a Lewis base linked by a coordinate covalent bond. (2) A species consisting of several ligands (the Lewis bases) that have an independent existence bonded to a single central metal atom or ion (the Lewis acid). *Examples:* (1) $H_3N{-}BF_3$; (2) $[Fe(H_2O)_6]^{3+}$; $[PtCl_4]^-$.
composite material A synthetic material composed of a polymer and one or more other substances that have been solidified together.
compound (1) A specific combination of elements that can be separated into its elements by chemical techniques but not physical techniques. (2) A substance consisting of atoms of two or more elements in a definite, unchangeable ratio.
compress To reduce the volume of a sample.
compressible Able to be compressed into a smaller volume.
compression factor (Z) The ratio of the actual molar volume of a gas to the molar volume of an ideal gas under the same conditions.
computational chemistry The application of computational techniques to the determination of the structures and properties of molecules and bulk matter.
concentration The quantity of a substance in a given volume. See also *molar concentration*.
concentration cell A galvanic cell in which the electrodes have the same composition but are at different concentrations.
condensation The formation of a liquid or solid phase from the gas phase of the substance.
condensation polymer A polymer formed by a chain of condensation reactions. *Examples:* polyesters; polyamides (nylon).
condensation reaction A reaction in which two molecules combine to form a larger one and a small molecule is eliminated. *Example:* $CH_3COOH + C_2H_5OH \longrightarrow CH_3COOC_2H_5 + H_2O$.
condensed phase A solid or liquid phase; not a gas.
condensed structural formula A compact version of the structural formula, showing how the atoms are grouped together. *Example:* $CH_3CH(CH_3)CH_3$ for methylpropane.
conduction band An incompletely occupied band of energy levels in a solid.
configuration See *electron configuration*.
conformations Molecular shapes that can be interchanged by rotation about bonds, without bond breakage and reformation.
congeners Elements in the same group of the periodic table.
conjugate acid The Brønsted acid formed when a Brønsted base has accepted a proton. *Example:* NH_4^+ is the conjugate acid of NH_3.
conjugate acid–base pair A Brønsted acid and its conjugate base. *Examples:* HCl and Cl^-; NH_4^+ and NH_3.
conjugate base The Brønsted base formed when a Brønsted acid has donated a proton. *Example:* NH_3 is the conjugate base of NH_4^+.
conjugated double bonds A sequence of alternating single and double bonds, as in $-C{=}C{-}C{=}C-$.
connectivity (of atoms in a molecule) The pattern in which the atoms in a molecule are bonded to one another.
constructive interference Interference that results in an increased amplitude of a wave. Compare with *destructive interference*.
contact process The production of sulfuric acid by the combustion of sulfur and the catalyzed oxidation of sulfur dioxide to sulfur trioxide.
conversion factor A factor that is used to convert a measurement from one unit into another.
cooling curve A graph of the variation of the temperature of a sample over time as it loses energy at a constant rate. Compare with *heating curve*.
Cooper pair A pair of electrons that can travel together almost freely through a crystal lattice and give rise to superconductivity.
coordinate Use of a lone pair to form a coordinate covalent bond. *Examples:* $F_3B + {:}NH_3 \longrightarrow F_3B{-}NH_3$; $Ni + 4\,CO \longrightarrow Ni(CO)_4$.
coordinate covalent bond A bond formed between a Lewis base and a Lewis acid by sharing an electron pair originally belonging to the Lewis base. See *coordinate*.
coordination complex The product of the reaction of a Lewis acid and a Lewis base to form a coordinate covalent bond. See also *coordination compound*.
coordination compound A neutral complex or an ionic compound in which at least one of the ions is a complex. *Examples:* $Ni(CO)_4$; $K_3[Fe(CN)_6]$.
coordination isomers Isomers that differ by the exchange of one or more ligands between a cationic complex and an anionic complex.
coordination number (1) The number of nearest neighbors of an atom in a solid. (2) For ionic solids, the coordination number of an ion is the number of nearest neighbors of opposite charge. (3) For complexes, the number of points at which ligands are attached to the central metal ion.
coordination sphere The ligands directly attached to the central ion in a complex.
copolymer A polymer formed from a mixture of different monomers. In *random copolymers,* the sequence of monomers has no particular order; in *alternating copolymers,* two monomers alternate; in *block copolymers,* regions of one monomer alternate with regions of another; in *graft copolymers,* chains of one monomer are attached to a backbone chain of a second monomer.
core The inner closed shells of an atom.
core electrons The electrons that belong to an atom's core.

corrosion The unwanted reaction of a material that results in the dissolution or consumption of the material. *Example:* the unwanted oxidation of a metal.

corrosive (1) A reagent that can cause corrosion. (2) Having a high reactivity, such as the reactivity of a strong oxidizing agent or a concentrated acid or base.

coulombic attraction The attraction between opposite electric charges.

Coulomb potential energy The potential energy of an electric charge in the vicinity of another electric charge; the potential energy is inversely proportional to the separation of the charges.

Coulomb's law The potential energy of a pair of electric charges is inversely proportional to the distance between them and proportional to the product of the charges.

couple See *redox couple*.

covalent bond A pair of electrons shared between two atoms.

covalent radius The contribution of an atom to the length of a covalent bond.

cracking The process of converting petroleum fractions into smaller molecules with more double bonds. *Example:* $CH_3(CH_2)_6CH_3 \rightarrow CH_3(CH_2)_3CH_3 + CH_3CH{=}CH_2$.

critical mass The mass of fissionable material above which so few neutrons escape from a sample of nuclear fuel that the fission chain reaction is sustained; a greater mass is *supercritical* and a smaller mass is *subcritical*.

critical point The point in a phase diagram at the critical pressure and critical temperature.

critical pressure (P_c) The vapor pressure of a liquid at its critical temperature.

critical temperature (T_c) The temperature at and above which a substance cannot exist as a liquid.

crown ether A cyclic ether with alternating $—CH_2CH_2O—$ units.

cryogenics The study of matter at very low temperatures.

cryoscopy The measurement of molar mass by using the depression of freezing point.

crystal face A flat plane forming a side of a crystal.

crystal field The electrostatic influence of the ligands (modeled as point negative charges) on the central ion of a complex. *Crystal field theory* is a rationalization of the optical, magnetic, and thermodynamic properties of complexes in terms of the crystal field of their ligands.

crystalline solid A solid in which the atoms, ions, or molecules lie in an orderly array. *Examples:* NaCl; diamond; graphite. Compare with *amorphous solid*.

crystallization The process in which a solute comes out of solution as crystals.

cubic close-packed structure (ccp) A close-packed structure with an ABCABC . . . pattern of layers.

curie (Ci) A unit of activity (for radioactivity).

current (I) The rate of supply of charge; current is measured in *amperes* (A), with $1\ A = 1\ C{\cdot}s^{-1}$.

cycle (1) In thermodynamics, a sequence of changes that begins and ends at the same state. (2) In spectroscopy, one complete reversal of the direction of the electromagnetic field and its return to the original direction.

cycloalkane A saturated aliphatic hydrocarbon in which the carbon atoms form a ring. *Example:* C_6H_{12}, cyclohexane.

Dalton's law of partial pressures The total pressure of a mixture of gases is the sum of the partial pressures of its components.

data The information provided or obtained from experiments.

daughter nucleus A nucleus that is the product of a nuclear decay.

d–d transition A transition in which an electron is excited from one d-orbital to another.

de Broglie relation The proposal that every particle has wavelike properties and that its wavelength, λ, is related to its mass by $\lambda = h/(\text{mass} \times \text{velocity})$.

debye (D) The unit used to report electric dipole moments: $1\ D = 3.336 \times 10^{-30}\ C{\cdot}m$.

decant To pour off a liquid from on top of another, denser liquid or from a solid.

decay constant (k) The rate constant for radioactive decay.

decomposition A reaction in which a substance is broken down into simpler substances; *thermal decomposition* is decomposition brought about by heat. *Example:* $CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$.

definite integral An *integral* with limits attached. See also Appendix 1F.

degenerate Having the same energy. *Example:* atomic orbitals in the same subshell.

dehydrating agent A reagent that removes water or the elements of water from a compound. *Example:* H_2SO_4.

dehydrogenation The removal of a hydrogen atom from each of two neighboring carbon atoms, resulting in the formation of a carbon–carbon multiple bond.

dehydrohalogenation The removal of a hydrogen atom and a halogen atom from neighboring carbon atoms in a haloalkane.

delocalized Spread over a region. In particular, *delocalized electrons* are electrons that spread over several atoms in a molecule.

delta (Δ, in a chemical equation) A symbol that signifies that the reaction takes place at elevated temperatures.

delta X (ΔX) The difference between the final and initial values of a property, $\Delta X = X_{final} - X_{initial}$. *Examples:* ΔT; ΔE.

denaturation The loss of structure of a large molecule, such as a protein.

density (d) The mass of a sample of a substance divided by its volume: $d = m/V$.

density isosurface A graphic image that represents a molecular structure as a surface and shows the distribution of electrons in a molecule; the surface corresponds to locations with the same electron density.

deposition The condensation of a vapor directly to a solid. Deposition is the reverse of *sublimation*.

deprotonation Loss of a proton from a Brønsted acid. *Example:* $NH_4^+(aq) + H_2O(l) \rightarrow H_3O^+(aq) + NH_3(aq)$.

derived unit A combination of base units. *Examples:* centimeters cubed (cm^3); joules ($kg{\cdot}m^2{\cdot}s^{-2}$).

descriptive chemistry The description of the preparation, properties, and applications of the elements and their compounds.

destructive interference Interference that results in a reduced amplitude of a wave. Compare with *constructive interference*.

deuteron The nucleus of a deuterium atom, $^{2}H^{+}$, consisting of a proton and a neutron.

diagonal relationship A similarity in properties between diagonal neighbors in the periodic table, especially for main-group elements in Periods 2 and 3 at the left-hand side of the table. *Examples:* Li and Mg; Be and Al.

diamagnetic (substance) A substance that tends to be pushed out of a magnetic field; consisting of atoms, ions, or molecules with no unpaired electrons. *Examples:* most common substances.

diamine An organic compound that contains two $-NH_2$ groups.

diathermic Permitting the passage of energy as heat. *Example:* diathermic walls.

diatomic ion An ion that consists of two atoms with a net charge.

diatomic molecule A molecule that consists of two atoms. *Examples:* H_2; CO.

differential calculus The part of mathematics that deals with the slopes of curves and with infinitesimal quantities. See also Appendix 1F.

diffraction The deflection of waves and the resulting interference caused by an object in their path. See also *x-ray diffraction*.

diffraction pattern The pattern of bright spots against a dark background resulting from diffraction.

diffusion The spreading of one substance through another substance.

dilute (1) verb: To reduce the concentration of a solute by adding more solvent. (2) adjective: Describes a solution in which the solute has a low concentration.

dimer The union of two identical molecules. *Example:* Al_2Cl_6 formed from two $AlCl_3$ molecules.

diol An organic compound with two –OH groups.

dipeptide A *peptide* formed by the condensation of two amino acids.

dipole See *electric dipole; instantaneous dipole moment*.

dipole–dipole interaction The interaction between two electric dipoles: like partial charges repel and opposite partial charges attract.

dipole–induced-dipole interaction The interaction between an electric dipole and the instantaneous dipole that it induces in a nonpolar molecule.

dipole moment See *electric dipole moment*.

diprotic An acid with two acidic hydrogen atoms. See also *polyprotic acid or base*.

disaccharide A carbohydrate molecule that is composed of two saccharide units. *Example:* $C_{12}H_{22}O_{11}$, sucrose.

dispersion (1) The spatial separation of light into its component colors (as by a prism). (2) See *suspension*.

dispersion force See *London force*.

disproportionation A redox reaction in which a single element is simultaneously oxidized and reduced. *Example:* $2\ Cu^{+}(aq) \longrightarrow Cu(s) + Cu^{2+}(aq)$.

dissociation (1) The breaking of a bond. (2) The separation of ions that occurs when an ionic solid dissolves.

dissociation constant See *acidity constant*.

dissociation energy (D) The energy required to separate bonded atoms.

distillate A liquid obtained by distillation.

distillation The separation of the components of a mixture by making use of their different volatilities.

distribution (of molecular speeds) The fraction of gas molecules moving at each speed at any instant.

disulfide link An —S—S— link that contributes to the secondary and tertiary structures of polypeptides.

domain A region of a metal in which the electron spins of the atoms are aligned, resulting in *ferromagnetism*.

doping The addition of a known, small amount of a second substance to an otherwise pure solid substance.

d-orbital See *atomic orbital*.

dose equivalent The actual dose of radiation experienced by a sample, modified to take into account the *relative biological effectiveness* of the radiation. The dose equivalent is measured in sievert (and formerly rem).

double bond (1) Two electron pairs shared by neighboring atoms. (2) One σ-bond and one π-bond between neighboring atoms.

drying agent A substance that absorbs water and thus maintains a dry atmosphere. *Example:* phosphorus(V) oxide.

ductility The ability to be drawn out into a wire (as for a metal).

duplet The $1s^2$ electron pair of the heliumlike electron configuration.

dynamic equilibrium The condition in which a forward process and its reverse are taking place simultaneously at equal rates. *Examples:* vaporizing and condensing; chemical reactions at equilibrium.

effective nuclear charge (Z_{eff}) The net nuclear charge after taking into account the shielding caused by other electrons in the atom.

effervesce To bubble out of solution as a gas.

effusion The escape of a substance (particularly a gas) through a small hole.

elasticity The ability to return to the original shape after distortion.

elastomer An elastic polymer. *Example:* rubber (polyisoprene).

electrical conduction The conduction of electric charge through matter. See also *electronic conductor; ionic conduction*.

electric conductivity (κ) A measure of the ability of a substance to conduct electricity (in siemens per meter).

electric current See *current*.

electric dipole A positive charge next to an equal but opposite negative charge.

electric dipole moment (μ) The magnitude of the electric dipole (in debye).

electric field A region of influence that affects charged particles.

electrochemical cell A system consisting of two electrodes in contact with an electrolyte. A *galvanic cell* (*voltaic cell*) is an electrochemical cell used to produce electricity, and an *electrolytic cell* is an electrochemical cell in which an electric current is used to cause chemical change.

electrochemical series Redox couples arranged in order of oxidizing and reducing strengths; usually arranged with strong oxidizing agents at the top of the list and strong reducing agents at the bottom.

electrochemistry The branch of chemistry that deals with the use of chemical reactions to produce electricity, the relative strengths of oxidizing and reducing agents, and the use of electricity to produce chemical change.

electrode A metallic conductor that makes contact with an electrolyte in an electrochemical cell. A *half-cell* is sometimes also referred to as an electrode.

electrolysis A process in which a chemical change is produced by passing an electric current through a liquid.

electrolyte (1) An ionically conducting medium. (2) A substance that dissolves to give an electrically conducting solution. A *strong electrolyte* is a substance that is fully ionized in solution. A *weak electrolyte* is a molecular substance that is only partially ionized in solution. A *nonelectrolyte* does not ionize in solution. *Examples:* NaCl is a strong electrolyte; CH_3COOH is a weak electrolyte; $C_6H_{12}O_6$ is a nonelectrolyte.

electrolyte solution A solution of an electrolyte.

electrolytic cell See *electrochemical cell*.

electromagnetic field The region of influence generated by accelerated charged particles.

electromagnetic radiation A wave of oscillating electric and magnetic fields; includes light, x-rays, and γ-rays.

electromotive force (emf) See *cell potential*.

electron (e^-) A negatively charged subatomic particle found outside the nucleus of an atom.

electron affinity (E_{ea}) The energy released when an electron is added to a gas-phase atom or monatomic ion.

electron arrangement (VSEPR model) The three-dimensional geometry of the arrangement of bonds and lone pairs about a central atom in a molecule or ion.

electron capture The capture by a nucleus of one of its own atom's s-electrons.

electron configuration The occupancy of orbitals in an atom or molecule. *Example:* N, $1s^22s^22p^3$.

electron-deficient compound A compound with too few valence electrons for it to be assigned a valid Lewis structure. *Example:* B_2H_6.

electronegative element An element with a high electronegativity. *Examples:* O; F.

electronegativity (χ, chi) The ability of an atom to attract electrons to itself when it is part of a compound.

electronic conductor A substance that conducts electricity by the transfer of electrons.

electronic structure The details of the distribution of the electrons that surround the nuclei in atoms and molecules.

electronvolt (eV) A unit of energy; the change in potential energy of an electron when it moves through a potential difference of 1 V; $1\ \text{eV} = 1.602\ 18 \times 10^{-19}$ J.

electrophile A reactant that is attracted to a region of high electron density. *Examples:* Br_2; NO_2^+.

electrophilic substitution Substitution that takes place as a result of an attack by an *electrophile*. *Example:* nitration of benzene.

electroplating The deposition of a thin film of metal on an object by electrolysis.

electropositive element An element that has a low electronegativity and is likely to give up electrons to another element on compound formation. *Examples:* Cs; Mg.

electrostatic potential surface A molecular structure in which the net charge is calculated at each point of the density isosurface and depicted by different colors; an "elpot" surface.

element (1) A substance that cannot be separated into simpler components by chemical techniques. (2) A substance consisting of atoms of the same atomic number. *Examples:* hydrogen; gold; uranium.

elementary reaction An individual step in a proposed reaction mechanism.

elimination reaction A reaction in which two groups or atoms on neighboring carbon atoms are removed from a molecule, thereby leaving a multiple bond between the carbon atoms. *Example:* $CH_3CHBrCH_3 + OH^- \rightarrow CH_3CH{=}CH_2 + H_2O + Br^-$.

empirical Determined by experiment.

empirical formula A chemical formula that shows the relative numbers of atoms of each element in a compound by using the simplest whole-number subscripts. *Examples:* P_2O_5; CH for benzene.

emulsion A suspension of droplets of one liquid dispersed throughout another liquid.

enantiomers A pair of optical isomers that are mirror images of, but not superimposable on, each other.

endothermic process A process that absorbs heat ($\Delta H > 0$). *Examples:* vaporization; $N_2O_4(g) \rightarrow 2\ NO_2(g)$.

end point The stage in a titration at which enough titrant has been added to bring the indicator to a color halfway between its initial and its final colors.

energy (E) The capacity of a system to do work or supply heat. *Kinetic energy* is the energy of motion, and *potential energy* is the energy arising from position. The *total energy* is the sum of the kinetic and potential energies.

energy level A permitted value of the energy in a quantized system such as an atom or a molecule.

enrich In nuclear chemistry, to increase the abundance of a specific isotope.

ensemble A collection of hypothetical replications of a system.

enthalpy (H) A state property; $H = U + PV$. A change in enthalpy is equal to the heat transferred at constant pressure.

enthalpy density (of a fuel) The enthalpy of combustion per liter (without the negative sign).

enthalpy of freezing The enthalpy change per mole accompanying freezing; the negative of the *enthalpy of fusion*.

enthalpy of fusion (ΔH_{fus}) The enthalpy change per mole accompanying fusion (melting).

enthalpy of hydration (ΔH_{hyd}) The enthalpy change accompanying the hydration of gas-phase ions.

enthalpy of melting (ΔH_{melt}) See *enthalpy of fusion*.

enthalpy of mixing (ΔH_{mix}) The change in enthalpy when two fluids (liquids or gases) mix.

enthalpy of solution (ΔH_{sol}) The change in enthalpy when a substance dissolves. The *limiting enthalpy of solution* is the enthalpy of solution for the formation of an infinitely dilute solution.

enthalpy of sublimation (ΔH_{sub}) The enthalpy change per mole accompanying sublimation (the direct conversion of a solid into a vapor).

enthalpy of vaporization (ΔH_{vap}) The enthalpy change per mole accompanying vaporization (the conversion of a substance from the liquid state into the vapor state).

entropy (S) (1) A measure of the disorder of a system. (2) A change in entropy is equal to the heat supplied reversibly to a system divided by the temperature at which the transfer takes place.

entropy of vaporization (ΔS_{vap}) The entropy change per mole accompanying vaporization (the conversion of a substance from the liquid state into the vapor state).

enzyme A biological catalyst.

e-orbital One of the orbitals d_{z^2} or $d_{x^2-y^2}$ in an octahedral or tetrahedral complex. In an octahedral complex, the orbitals are designated e_g.

equation of state A mathematical expression relating the pressure, volume, temperature, and amount of substance present in a sample. *Example:* ideal gas law, $PV = nRT$.

equatorial bond A bond perpendicular to the axis of a molecule (particularly trigonal bipyramidal and octahedral molecules).

equatorial lone pair A *lone pair* in the plane perpendicular to the molecular axis.

equilibrium See *chemical equilibrium; dynamic equilibrium*.

equilibrium constant (K) An expression characteristic of the equilibrium composition of the reaction mixture, with a form given by the law of mass action. *Example:* $N_2(g) + 3\,H_2(g) \rightleftharpoons 2\,NH_3(g)$, $K = (P_{NH_3})^2/P_{N_2}(P_{H_2})^3$.

equilibrium table A table used to calculate the composition of a reaction mixture at equilibrium, given the initial composition. The columns are headed by the species and the rows are, successively, the initial composition, the change to reach equilibrium, and the equilibrium composition.

equimolar Having the same molar concentration or the same number of moles.

equipartition theorem The average energy of each quadratic contribution to the energy of a molecule in a sample at a temperature T is equal to $\frac{1}{2}kT$ (where k is *Boltzmann's constant*).

equivalence point See *stoichiometric point*.

essential amino acid An amino acid that is an essential component of the diet because it cannot be synthesized in the body.

ester The product (other than water) of the reaction between a carboxylic acid and an alcohol and having the formula RCOOR′. *Example:* $CH_3COOC_2H_5$, ethyl acetate.

esterification The formation of an *ester*.

ether An organic compound of the form R—O—R′. *Examples:* $CH_3OC_2H_5$, ethyl methyl ether; $C_2H_5OC_2H_5$, diethyl ether.

evaporate To vaporize completely.

excited state A state other than the state of lowest energy.

exclusion principle No more than two electrons can occupy any given orbital; and, when two electrons do occupy one orbital, their spins must be paired.

exothermic process A process that releases heat ($\Delta H < 0$). *Examples:* freezing; $N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g)$.

expanded valence shell A valence shell containing more than eight electrons. Also called an *expanded octet*. *Examples:* the valence shells of P and S in PCl_5 and SF_6.

expansion work See *work*.

experiment A test carried out under carefully controlled conditions.

exponential The exponential of x is the natural antilogarithm of x, namely, e^x.

exponential decay A variation with time of the form e^{-kt}. *Example:* $[A] = [A]_0e^{-kt}$.

extensive property A physical property that depends on the size of the sample. *Examples:* volume; internal energy; enthalpy; entropy.

extrapolate To extend a graph outside the region covered by the data.

extrinsic semiconductor A material in which semiconduction arises from the presence of a low concentration of a dopant. *Example:* Arsenic added to very pure silicon.

face See *crystal face*.

face-centered cubic structure (fcc) A crystal structure built from a cubic unit cell in which there is an atom at the center of each face and one at each corner.

Fahrenheit scale A temperature scale on which the freezing point of water is at 32 degrees and the normal boiling point is at 212 degrees. Units on this scale are degrees Fahrenheit, °F.

fallout The fine dust that settles from clouds of airborne particles after a nuclear bomb test.

Faraday's constant (F) The magnitude of the charge per mole of electrons; $F = N_Ae = 96.485\ kC{\cdot}mol^{-1}$.

Faraday's law of electrolysis The amount of product formed by an electric current is chemically equivalent to the amount of electrons supplied.

fat An ester of glycerol and carboxylic acids with long hydrocarbon chains; fats act as long-term energy storage in living systems.

fatty acid A carboxylic acid with a long hydrocarbon chain. *Example:* $CH_3(CH_2)_{16}COOH$, stearic acid.

ferrimagnetic material A material in which the electron spins on neighboring atoms are different and locked together in an antiferromagnetic arrangement.

ferroalloy An alloy of a metal with iron and, often, carbon. Example: ferrovanadium.

ferrofluid A magnetic liquid that is a suspension of a finely powdered magnetic material such as magnetite, Fe_3O_4, in a viscous, oily liquid (such as mineral oil) that contains a detergent.

ferromagnetic material See *ferromagnetism*.

ferromagnetism The ability of some substances to be permanently magnetized; the electron spins of neighboring atoms are aligned. *Examples:* iron; magnetite, Fe_3O_4.

ferrous alloy An alloy based on iron and often including various other d-block metals. *Examples:* The varieties of steels.

field An influence spreading over a region of space. *Examples:* an *electric field* from a charge; a *magnetic field* from a magnet or a moving charge.

filtration The separation of a heterogeneous mixture of a solid and liquid by passing the mixture through a fine mesh.

first derivative (dy/dx) A measure of the slope of a curve. See also Appendix 1F.
first ionization energy (I_1) See *ionization energy*.
first law of thermodynamics The internal energy of an isolated system is constant.
first-order reaction A reaction in which the rate is proportional to the first power of the concentration of a substance.
fissile nucleus A nucleus having the ability to undergo fission induced by slow neutrons. *Example:* ^{235}U is fissile.
fission (nuclear) The breakup of a nucleus into two smaller nuclei of similar mass; fission may be *spontaneous* or *induced* (particularly by the impact of neutrons).
fissionable Having the ability to undergo induced nuclear fission.
fix (nitrogen) Convert elemental nitrogen to its compounds, particularly ammonia.
flammability The ability of a substance to burn in air.
flocculation The reversible aggregation of colloidal particles into larger particles that can be filtered.
fluorescence The emission of light from molecules excited by radiation of higher frequency.
foam (1) A frothy collection of bubbles formed by a liquid. (2) A type of *colloid* formed by a gas of tiny bubbles in a liquid or solid.
f-orbital See *atomic orbital*.
force (F) An influence that changes the state of motion of an object. *Examples:* an electrostatic force from an electric charge; a mechanical force from an impact.
formal anhydride An *acid anhydride* that does not necessarily react with water to form the corresponding acid. *Example:* CO, the formal anhydride of formic acid, HCOOH.
formal charge (1) The electric charge of an atom in a molecule assigned on the assumption that the bonding is nonpolar covalent. (2) Formal charge (FC) = number of valence electrons in the free atom − (number of lone-pair electrons + $\frac{1}{2}$ × number of shared electrons).
formation constant (K_f) The equilibrium constant for complex formation. The *overall formation constant* is the product of *step-by-step formation constants*. The inverse of the formation constant ($1/K_f$) is called the *stability constant*.
formula unit The group of ions that matches the formula of the smallest unit of an ionic compound. *Example:* NaCl, one Na^+ ion and one Cl^- ion.
formula weight The numerical value of the *molar mass* of an ionic compound.
fossil fuel The partly decomposed remains of vegetable and marine life (mainly coal, oil, and natural gas).
fraction Samples of distillate obtained in different ranges of boiling temperatures.
fractional distillation Separation of the components of a liquid mixture by repeated distillation, making use of their differing volatilities.
Frasch process A process for mining sulfur that uses superheated water to melt the sulfur and compressed air to force it to the surface.
free energy See *Gibbs free energy*.
free expansion Expansion against zero opposing pressure.
freezing-point constant (k_f) The constant of proportionality between the freezing-point depression and the solute molality.
freezing-point depression The lowering of the freezing point of a solvent caused by the presence of a solute (a colligative property).
freezing temperature The temperature at which a liquid freezes. The *normal freezing point* is the freezing temperature under a pressure of 1 atm.
frequency (of radiation) (ν, nu) The number of cycles (repeats of the waveform) per second (unit: *hertz*, Hz).
fuel cell A primary electrochemical cell in which the reactants are supplied continuously from outside while the cell is in use.
functional group A group of atoms that brings a characteristic set of chemical properties to an organic molecule. *Examples:* —OH ; —Br ; —COOH.
functionalization The introduction of functional groups into an alkane molecule.
fundamental charge (e) The magnitude of the charge of an electron.
fusion (1) Melting. (2) The merging of nuclei to form the nucleus of a heavier element.

galvanic cell See *electrochemical cell*.
galvanize Coat a metal with an unbroken film of zinc.
gamma (γ) radiation Very high frequency, short-wavelength electromagnetic radiation emitted by nuclei.
gas A fluid form of matter that fills the container that it occupies and can easily be compressed into a much smaller volume. (A gas differs from a vapor in that a gas is a substance at a higher temperature than its critical temperature; a vapor is a gaseous form of matter at a temperature below its critical temperature.)
gas constant (R) (1) The constant that appears in the ideal gas law. See inside the back cover of the book for values. (2) $R = N_A k$, where k is *Boltzmann's constant*.
gas–liquid chromatography A version of chromatography in which a gas carries the sample over a stationary liquid phase.
gauge pressure The pressure inside a container less that outside the container.
Geiger counter A device that is used to detect and measure radioactivity by relying on ionization caused by incident radiation.
gel A soft, solid colloid that typically consists of a liquid trapped within a solid network.
geometrical isomers Stereoisomers that differ in the spatial arrangement of the atoms. Geometrical isomers exhibit *cis–trans* isomerism.
Gibbs free energy ($G = H - TS$) The energy of a system that is free to do work at constant temperature and pressure. The direction of spontaneous change at constant pressure and temperature is the direction of decreasing Gibbs free energy.
Gibbs free energy of reaction The difference in molar Gibbs free energies of the products and reactants, weighted by the stoichiometric coefficients in the chemical equation.
glass An ionic solid with an amorphous structure resembling that of a liquid.
glass electrode A thin-walled glass bulb containing an electrolyte solution and a metallic contact; used for measuring pH.
graft copolymer See *copolymer*.

Graham's law of effusion The rate of effusion of a gas is inversely proportional to the square root of its molar mass.
gravimetric analysis An analytical method using measurements of mass.
gray (Gy) The SI unit of *absorbed dose;* 1 Gy corresponds to an energy deposit of $1\ J\cdot kg^{-1}$. See also *rad*.
green chemistry The practice of chemistry that conserves resources and minimizes impact on the environment.
greenhouse effect The blocking by some atmospheric gases (notably carbon dioxide) of the radiation of heat from the surface of the Earth back into space, leading to the possibility of a worldwide rise in temperature.
greenhouse gas A gas that contributes to the *greenhouse effect*.
ground state The state of lowest energy.
group A vertical column in the periodic table.

Haber process (Haber–Bosch process) The catalyzed synthesis of ammonia at high pressure.
half-cell One compartment of an electrochemical cell consisting of an electrode and an electrolyte.
half-life ($t_{1/2}$) (1) In chemical kinetics, the time needed for the concentration of a substance to fall to half its initial value. (2) In radioactivity, the time needed for half the initial number of radioactive nuclei to disintegrate.
half-reaction A hypothetical oxidation or reduction reaction showing either electron loss or electron gain. *Examples:* $Na(s) \rightarrow Na^+(aq) + e^-$; $Cl_2(g) + 2\ e^- \rightarrow 2\ Cl^-(aq)$.
halide ion An anion formed from a halogen atom. *Examples:* F^-; I^-.
Hall process (Hall–Hérault process) The production of aluminum by the electrolysis of aluminum oxide dissolved in molten cryolite.
haloalkane An alkane with a halogen substituent. *Example:* CH_3Cl, chloromethane.
halogen A member of Group 17/VII.
halogenation The incorporation of a halogen into a compound (particularly, into an organic compound).
hamiltonian The operator H in the Schrödinger equation; $H\psi = E\psi$.
hard matter Solid matter that can withstand strong forces without deforming.
hard water Water that contains dissolved calcium and magnesium salts.
heat (q) The energy that is transferred as the result of a temperature difference between a system and its surroundings.
heat capacity (C) The ratio of heat supplied to the temperature rise produced. The *heat capacity at constant pressure*, C_P, and the *heat capacity at constant volume*, C_V, are normally distinguished. See also *molar heat capacity; specific heat capacity*.
heating The act of transferring energy as heat.
heating curve A graph of the variation of the temperature of a sample as it is heated at a constant rate.
Heisenberg uncertainty principle If the location of a particle is known to within an uncertainty Δx, then the linear momentum parallel to the x-axis can be known only to within an uncertainty Δp, where $\Delta p \Delta x \geq \hbar/2$.
Henderson–Hasselbalch equation An approximate equation for estimating the pH of a solution containing a conjugate acid and base. See also Section 12.2.
Henry's constant The constant k_H that appears in *Henry's law*.
Henry's law The solubility of a gas in a liquid is proportional to its partial pressure above the liquid: solubility $= k_H \times$ *partial pressure*.
hertz (Hz) The SI unit of frequency: 1 Hz is one complete cycle per second; $1\ Hz = 1\ s^{-1}$.
Hess's law A reaction enthalpy is the sum of the enthalpies of any sequence of reactions (at the same temperature and pressure) into which the overall reaction can be divided.
heterogeneous alloy See *alloy*.
heterogeneous catalyst See *catalyst*.
heterogeneous equilibrium An equilibrium in which at least one substance is in a different phase from the others. *Example:* $AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$.
heterogeneous mixture A mixture in which the individual components, although mixed together, lie in distinct regions that can be distinguished with an optical microscope. *Example:* a mixture of sand and sugar.
heterolytic dissociation Dissociation into ions. *Example:* $CH_3I \rightarrow CH_3^+ + I^-$. Compare with *homolytic dissociation*.
heteronuclear diatomic molecule A molecule consisting of two atoms of different elements. *Examples:* HCl; CO.
hexagonal close-packed structure (hcp) A close-packed structure with an ABABAB . . . pattern of layers.
high-boiling azeotrope See *azeotrope*.
highest occupied molecular orbital (HOMO) The highest-energy molecular orbital in the ground state of a molecule occupied by at least one electron.
high-spin complex A d^n complex with the maximum number of unpaired electron spins.
high-temperature superconductor A material that becomes superconducting at temperatures well above the transition temperature for the first generation of superconductors, typically 100 K and above.
homeostasis The maintenance of constant physiological conditions.
homogeneous alloy See *alloy*.
homogeneous catalyst See *catalyst*.
homogeneous equilibrium A chemical equilibrium in which all the substances taking part are in the same phase. *Example:* $H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$.
homogeneous mixture A mixture in which the individual components are uniformly mixed, even on a molecular scale. *Examples:* air; solutions.
homolytic dissociation Dissociation into radicals. *Example:* $CH_3I \rightarrow \cdot CH_3 + \cdot I$. Compare with *heterolytic dissociation*.
homonuclear diatomic molecule A molecule consisting of two atoms of the same element. *Examples:* H_2; N_2.
Hund's rule If more than one orbital in a subshell is available, add electrons with parallel spins to different orbitals of that subshell.
hybridization The formation of *hybrid orbitals*.
hybrid orbital A mixed orbital formed by blending together atomic orbitals on the same atom. *Example:* an sp^3 hybrid orbital.
hydrate A solid compound containing H_2O molecules. *Example:* $CuSO_4\cdot 5H_2O$.
hydrated Having water molecules attached. See *hydration*.

hydrate isomers Isomers that differ by an exchange of an H_2O molecule and a ligand in the coordination sphere.

hydration (1) of ions: The attachment of water molecules to a central ion. (2) of organic compounds: The addition of water across a multiple bond (H to one carbon atom, OH to the other). *Example:* $CH_2{=}CH_2 + H_2O \rightarrow CH_3CH_2OH$.

hydride A binary compound of a metal or metalloid with hydrogen; the term is often extended to include all binary compounds of hydrogen. A *saline* or *saltlike hydride* is a compound of hydrogen and a strongly electropositive metal; a *molecular hydride* is a compound of hydrogen and a nonmetal; a *metallic hydride* is a compound of certain d-block metals and hydrogen.

hydrocarbon A binary compound of carbon and hydrogen. *Examples:* CH_4; C_6H_6.

hydrogenation The addition of hydrogen to multiple bonds. *Example:* $CH_3CH{=}CH_2 + H_2 \rightarrow CH_3CH_2CH_3$.

hydrogen bond A link formed by a hydrogen atom lying between two strongly electronegative atoms (O, N, or F). The electronegative atoms may be located on different molecules or in different regions of the same molecule.

hydrohalogenation The addition of a hydrogen halide to an alkene to form a haloalkane. *Example:* $CH_3CH{=}CH_2 + HCl \rightarrow CH_3CHClCH_3$.

hydrolysis reaction The reaction of water with a substance, resulting in the formation of a new element–oxygen bond. *Example:* $PCl_5(s) + 4\,H_2O(l) \rightarrow H_3PO_4(aq) + 5\,HCl(aq)$.

hydrolyze To undergo hydrolysis. See also *hydrolysis reaction*.

hydrometallurgical process The extraction of metals by reduction of their ions in aqueous solution. *Example:* $Cu^{2+}(aq) + Fe(s) \rightarrow Cu(s) + Fe^{2+}(aq)$.

hydronium ion The ion H_3O^+.

hydrophilic Water attracting. *Example:* hydroxyl groups are hydrophilic.

hydrophobic Water repelling. *Example:* hydrocarbon chains are hydrophobic.

hydrostatic pressure The pressure exerted by a column of fluid.

hydroxyl group An —OH group in an organic compound.

hypervalent compound A compound that contains an atom with more atoms attached than allowed by the octet rule. *Example:* SF_6.

hypothesis A suggestion put forward to account for a series of observations. *Example:* Dalton's atomic hypothesis.

ideal gas A gas that satisfies the ideal gas law and is described by the *kinetic model*.

ideal gas law ($PV = nRT$) All gases obey the law more and more closely as the pressure is reduced to very low values.

ideal solution A solution that obeys *Raoult's law* at any concentration; all solutions behave ideally as the concentration approaches zero. *Example:* benzene and toluene form an almost ideal system.

***i* factor** A factor that takes into account the existence of ions in an electrolyte solution, particularly for the interpretation of colligative properties. It indicates the number of particles formed from one formula unit of the solute. *Example:* $i \approx 2$ for very dilute NaCl(aq).

incandescence Light emitted by a hot body.

incomplete octet A valence shell of an atom that has fewer than eight electrons. *Example:* the valence shell of B in BF_3.

indefinite integral An *integral* without limits attached. See also Appendix 1F.

indicator A substance that changes color when it goes from its acidic to its basic form (an *acid–base indicator*) or from its oxidized to its reduced form (a *redox indicator*).

induced dipole moment An electric dipole moment produced in a polarizable molecule by a neighboring charge or partial charge.

induced-fit mechanism A model of the action of an enzyme in which the enzyme molecule adjusts its shape to accommodate the incoming substrate molecule. A modification of the *lock-and-key mechanism* of enzyme action.

induced nuclear fission See *fission*.

inert (1) Unreactive. (2) Thermodynamically unstable but survives for long periods (*nonlabile*).

inert-pair effect The observation that an element displays a valence lower than expected from its group number. An *inert pair* is a pair of valence shell s-electrons that are tightly bound to the atom and might not participate in bond formation.

infrared radiation Electromagnetic radiation with a lower frequency (longer wavelength) than that of red light but a higher frequency (shorter wavelength) than microwave radiation.

initial concentration (of a weak acid or base) The concentration as prepared, as if no deprotonation or protonation had taken place.

initial rate The rate at the start of the reaction when products are present in concentrations too low to affect the rate.

initiation The formation of reactive intermediates that serve as chain carriers from a reactant at the start of a chain reaction. *Example:* $Br_2 \rightarrow Br\cdot + Br\cdot$.

inner transition metal A member of the f-block of the periodic table (the *lanthanoids* and *actinoids*).

inorganic chemistry The study of the elements other than carbon and their compounds.

inorganic compound A compound that is not organic. See also *organic compound*.

insoluble substance A substance that does not dissolve in a specified solvent. When the solvent is not specified, water is generally meant.

instantaneous dipole moment A dipole moment that arises from a transient redistribution of charge and is responsible for the *London force*.

instantaneous rate The slope of the tangent of a graph of concentration against time.

insulator (electrical) A substance that does not conduct electricity. *Examples:* nonmetallic elements; molecular solids.

integral (1) The sum of infinitesimal quantities. (2) The inverse of a derivative in the sense that the integral of the first derivative of a function is the original function. See *definite integral*, *indefinite integral*.

integral calculus The part of mathematics that deals with the combination of infinitesimal quantities and the areas under curves. See also Appendix 1F.

integrated rate law An expression for the concentration of a reactant or product in terms of the time, obtained from the rate law of the reaction. *Example:* $[A] = [A]_0e^{-kt}$.
intensity The brightness of electromagnetic radiation. The intensity of a wave of electromagnetic radiation is proportional to the square of its *amplitude*.
intensive property A physical property of a substance that is independent of the size of the sample. *Examples:* density; molar volume; temperature.
intercept (of a graph) The value at which the line cuts the specified (usually vertical) axis. See also Appendix 1E.
interference Interaction between waves, leading to a greater amplitude (*constructive interference*) or to a smaller one (*destructive interference*).
interhalogen A binary compound of two halogens. *Example:* IF_3.
intermediate See *reaction intermediate*.
intermetallic compound An inorganic compound formed from two metals in specific proportions. *Examples:* NiTi, Ag_3Sn, FeCo.
intermolecular Between molecules.
intermolecular forces The forces of attraction and repulsion between molecules. *Examples:* hydrogen bonding; dipole–dipole force; London force. See also *van der Waals interactions*.
internal energy (U) In thermodynamics, the total energy of a system.
International System See *SI*.
internuclear axis The straight line between the nuclei of two bonded atoms.
interpolate To find a value between two measured values.
interstice A hole or gap in a crystal lattice.
interstitial alloy See *alloy*.
interstitial compound A compound in which one type of atom occupies the gaps in a lattice of other atoms. *Example:* an interstitial carbide.
intramolecular Within a molecule.
intrinsic semiconductor A pure substance in which an empty conduction band lies close in energy to a full valence band.
ion An electrically charged atom or group of atoms. *Examples:* Al^{3+}; SO_4^{2-}. See also *anion; cation*.
ion–dipole interaction The attraction between an ion and the opposite partial charge of the electric dipole of a polar molecule.
ion exchange The exchange of one type of ion in solution for another.
ionic bond The attraction between the opposite charges of cations and anions.
ionic character The extent to which ionic structures contribute to the resonance of a molecule or ion.
ionic compound A compound that consists of ions. *Examples:* NaCl; KNO_3.
ionic conduction Electrical conduction in which the charge is carried by ions. See also *electrical conduction; electronic conductor*.
ionic equation See *complete ionic equation*.
ionic liquid An ionic compound that is liquid at ordinary temperatures because one of its ions is a relatively large, organic ion. Ionic liquids are used as nontoxic, nonvolatile solvents.
ionic model The description of bonding in terms of ions.
ionic radius The contribution of an ion to the distance between neighboring ions in a solid ionic compound. In practice, the radius of an ion is defined as its contribution to the distance between the centers of neighboring ions, with the radius of the O^{2-} ion set equal to 140. pm.
ionic solid A solid built from cations and anions. *Examples:* NaCl; KNO_3.
ionization (1) of atoms and molecules: Conversion into ions by the transfer of electrons. *Example:* $K(g) \longrightarrow K^+(g) + e^-(g)$. (2) of acids and bases: See *protonation* and *deprotonation*.
ionization constant See *acidity constant*.
ionization energy (I) The minimum energy required to remove an electron from the ground state of a gaseous atom, molecule, or ion. The *first ionization energy* is the ionization energy for the removal of the first electron from an atom. The *second ionization energy* is the ionization energy for removal of a second electron, and so on.
ionization isomers Isomers that differ by the exchange of a ligand with an anion or neutral molecule outside the coordination sphere.
ionizing radiation High-energy radiation (typically but not necessarily nuclear radiation) that can cause ionization.
ion pair A cation and anion in close proximity.
ion-selective electrode An electrode sensitive to the concentration of a particular ion.
irreversible process A process that is not reversed by an infinitesimal change in a variable.
isoelectronic species Species with the same number of atoms and the same number of valence electrons. *Examples:* F^- and Ne; SO_2 and O_3; CN^- and CO.
isolated system See *system*.
isomer One of two or more compounds that contain the same number of the same atoms in different arrangements. In *structural isomers,* the atoms have different partners or lie in a different order; in *stereoisomers,* the atoms have the same partners but are in different arrangements in space. *Optical isomers* are related like an object and its mirror image; they are types of stereoisomers. *Examples:* CH_3OCH_3 and CH_3CH_2OH (structural isomers); *cis*- and *trans*-2-butene (stereoisomers).
isomerization A reaction in which a compound is converted into one of its isomers. *Example: cis*-butene $\longrightarrow$ *trans*-butene.
isotherm A line on a graph depicting the variation of a property at constant temperature.
isothermal change A change that occurs at constant temperature.
isotope One of two or more atoms that have the same atomic number but different mass number. *Example:* ^1H, ^2H, and ^3H are all isotopes of hydrogen.
isotopic abundance See *abundance*.
isotopic dating The determination of the age of objects by measuring the activity of the radioactive isotopes that they contain, particularly ^{14}C.
isotopic label See *tracer*.
isotopomers Molecules that differ in their isotopic composition. *Examples:* $^{12}CH_4$ and $^{13}CH_4$.
isotropic Not depending on orientation.

joule (J) The SI unit of energy ($1\ J = 1\ kg \cdot m^2 \cdot s^{-2}$).
Joule–Thomson effect The cooling of a gas as it expands.

Kekulé structures Two Lewis structures of benzene, consisting of alternating single and double bonds.
kelvin (K) The SI unit of temperature. See also Appendix 1B.
Kelvin scale A fundamental scale of temperature on which the triple point of water lies at 273.16 K and the lowest attainable temperature is at 0. The unit on the Kelvin scale is the *kelvin,* K.
ketone An organic compound containing a carbonyl group between two carbon atoms, having the form R—CO—R′. *Example:* CH_3—CO—CH_2CH_3, butanone.
kilogram (kg) The SI unit of mass. See also Appendix 1B.
kinetic energy (E_k) The energy of a particle due to its motion. Kinetic energy may be *translational* (arising from motion through space), *rotational* (arising from rotation about a center of mass), or *vibrational* (arising from the oscillating motion of the atoms in a molecule). *Example:* the translational kinetic energy of a particle of mass m and speed v is $\frac{1}{2}mv^2$.
kinetic model A model of the properties of an ideal gas in which pointlike molecules are in continuous random motion in straight lines until collisions occur between them.
kinetic molecular theory (KMT) The mathematical version of the *kinetic model* of gases.
Kirchhoff's law The relation between the standard reaction enthalpies at two temperatures in terms of the temperature difference and the difference in heat capacities (at constant pressure) of the products and reactants.

labeled The replacement of an atom in a compound with a radioisotope of the same element in order to allow very small amounts of the compound to be detected.
labile Refers to species that survive only for short periods.
lanthanide Former (and still widely used) term for *lanthanoid*.
lanthanide contraction The reduction of atomic radius of the elements following the lanthanides below the values that would be expected by extrapolation of the trend down a group (and arising from the poor shielding ability of f-electrons).
lanthanoid A member of the first row of the f-block (cerium through ytterbium).
lattice An orderly array of atoms, molecules, or ions in a crystal.
lattice energy The difference between the potential energy of ions in a crystal and that of the same widely separated ions in a gas.
lattice enthalpy The standard enthalpy change for the conversion of an ionic solid into a gas of ions.
law A summary of an extensive series of observations.
law of conservation of energy Energy can be neither created nor destroyed.
law of conservation of mass Matter (and specifically atoms) is neither created nor destroyed in a chemical reaction.
law of constant composition A compound has the same composition whatever its source.
law of mass action For an equilibrium of the form $a\ A + b\ B \rightleftharpoons c\ C + d\ D$, the ratio $a_C{}^c a_D{}^d / a_A{}^a a_B{}^b$ evaluated at equilibrium is equal to a constant K, which has a specific value for a given chemical equation and temperature.
law of partial pressures See *Dalton's law of partial pressures.*
law of radioactive decay The rate of decay is proportional to the number of radioactive nuclides in the sample.
LCAO and LCAO-MO See *linear combination of atomic orbitals.*
Le Chatelier's principle When a stress is applied to a system in dynamic equilibrium, the equilibrium adjusts to minimize the effect of the stress. *Example:* a reaction at equilibrium tends to proceed in the endothermic direction when the temperature is raised.
leveling The observation that strong acids all have the same strength in water, and all behave as though they were solutions of H_3O^+ ions.
Lewis acid An electron pair acceptor. *Examples:* H^+; Fe^{3+}; BF_3.
Lewis base An electron pair donor. *Examples:* OH^-; H_2O; NH_3.
Lewis formula (for an ionic compound) A representation of the structure of an ionic compound showing the formula unit of ions in terms of their Lewis diagrams.
Lewis structure A diagram showing how electron pairs are shared between atoms in a molecule. *Examples:* H—C̈l: and Ö=C=Ö.
Lewis symbol (for atoms and ions) The chemical symbol of an element, with a dot for each valence electron.
ligand A group attached to the central metal ion in a complex; a *polydentate ligand* occupies more than one binding site. See also *ambidentate ligand*.
ligand field splitting (Δ) The energy separation of the e- and t-orbitals in a complex induced by the presence of ligands.
ligand field theory The theory of bonding in d-metal complexes, a more complete version of *crystal field theory*. See also *crystal field*.
light See *visible radiation*.
limiting enthalpy of solution See *enthalpy of solution*.
limiting law A law that is accurately obeyed only at the limit of a property, such as when a property (the pressure of a gas, for example) is made very small.
limiting reactant The reactant that governs the theoretical yield of product in a given reaction.
linear combination of atomic orbitals (LCAO) A sum of atomic orbitals to form a molecular orbital (an LCAO-MO).
linear momentum (p) The product of mass and velocity.
line structure A representation of the structure of an organic molecule in which lines represent bonds; carbon atoms and the hydrogen atoms attached to them are not usually shown explicitly.
linkage isomers Isomers that differ in the identity of the atom that a ligand uses to attach to a metal ion.
lipid A naturally occurring organic compound that dissolves in hydrocarbons but not in water. *Examples:* fats; steroids; terpenes; the molecules that form cell membranes.
liquid A fluid form of matter that has a well-defined surface and takes the shape of the part of the container that it occupies.
liquid crystal A substance that flows like a liquid but has molecules that lie in a moderately orderly array. Liquid

crystals may be *nematic, smectic,* or *cholesteric,* depending on the arrangement of the molecules.

lock-and-key mechanism A model of enzyme action in which the enzyme is thought of as a lock and its substrate as a matching key.

logarithm If a number x is written as B^y, then y is the logarithm of x to the base B. For *common logarithms* (denoted $\log x$), $B = 10$. For *natural logarithms* (denoted $\ln x$), $B = e$. See also Appendix 1D.

London force The force of attraction that arises from the interaction between instantaneous electric dipoles on neighboring molecules.

lone pair A pair of valence electrons that is not taking part in bonding.

long period A period of the periodic table with more than eight members.

long-range order An orderly arrangement of atoms or molecules that is repeated over long distances.

lowest unoccupied molecular orbital (LUMO) The lowest-energy molecular orbital that is unoccupied in the ground state.

low-spin complex A d^n complex with the minimum number of unpaired electron spins.

luminescence The emission of light from a process, other than incandescence, that results from the formation of an excited state.

Lyman series A series of lines in the spectrum of atomic hydrogen in which the transitions are to orbitals with $n = 1$.

lyotropic liquid crystal A liquid crystal that results from the action of a solvent on a solute.

macroscopic level The level at which visible objects can be observed directly.

Madelung constant (A) A number that appears in the expression for the lattice energy and depends on the type of crystal lattice. *Example:* $A = 1.748$ for the rock-salt structure.

magic numbers The numbers of protons or neutrons that correlate with enhanced nuclear stability. *Examples:* 2, 8, 20, 50, 82, and 126.

magnetic field A region of influence that affects the motion of moving charged particles.

magnetic quantum number (m_l) The quantum number that identifies the individual orbitals of a subshell of an atom and determines their orientation in space.

main group Any one of the groups forming the s- and p-blocks of the periodic table (Groups 1, 2, and 13/III through 18/VIII).

malleability The ability to be deformed by being struck by a hammer (as a metal).

manometer An instrument used for measuring the pressure of a gas confined inside a container.

mantissa (of a logarithm) The numbers to the right of the decimal point.

many-electron atom An atom with more than one electron.

mass (m) The quantity of matter in a sample.

mass number (A) The total number of nucleons (protons plus neutrons) in the nucleus of an atom. *Example:* ^{14}C, with mass number 14, has 14 nucleons (6 protons and 8 neutrons).

mass percentage composition The mass of a substance present in a sample, expressed as a percentage of the total mass of the sample.

mass spectrometer An instrument used in *mass spectrometry.*

mass spectrometry Technique for measuring the masses and abundances of atoms and molecules by passing a beam of ions through a magnetic field.

mass spectrum The display of the relative number of particles with each specified mass; the output generated by the detector of a mass spectrometer. See also *mass spectrometry.*

material balance The requirement that the sum of the concentrations of all forms of a solute in a solution be equal to the initial concentration of the solute. *Example:* the sum of the concentrations of HCN and CN^- in an aqueous solution of HCN is equal to the initial concentration of HCN.

materials science The study of the chemical structures, compositions, and properties of materials.

matter Anything that has mass and takes up space.

maximum-boiling azeotrope See *azeotrope.*

Maxwell distribution of molecular speeds The formula for calculating the percentage of molecules that move at any given speed in a gas at a specified temperature.

mean bond enthalpy (ΔH_B) The mean of A—B bond enthalpies for a number of different molecules containing the A—B bond. See also *bond enthalpy.*

mean free path The average distance that a molecule travels between collisions.

mean relative speed The mean speed at which two molecules approach each other in a gas.

mechanical equilibrium The state in which the pressure of a system is equal to that of its surroundings.

mechanism See *reaction mechanism.*

medicinal chemistry The application of chemical principles to the development of pharmaceuticals.

melting temperature The temperature at which a substance melts. The *normal melting point* is the melting point under a pressure of 1 atm.

meniscus The curved surface that a liquid forms in a narrow tube.

mesophase A state of matter showing some of the properties of both a liquid and a solid (a liquid crystal).

metal (1) A substance that conducts electricity, has a metallic luster, is malleable and ductile, forms cations, and has basic oxides. (2) A metal consists of cations held together by a sea of electrons. *Examples:* iron; copper; uranium.

metallic bond The form of bonding characteristic of metals in which cations are held together by a sea of electrons.

metallic conductor An electronic conductor with a resistance that increases as the temperature is raised.

metallic hydride See *hydride.*

metallic solid See *metal.*

metallocene A compound in which a metal atom lies between two cyclic ligands, thus resembling a sandwich. *Example:* ferrocene (dicyclopentadienyliron(0), $[Fe(C_5H_5)_2]$).

metalloid An element that has the physical appearance and properties of a metal but behaves chemically like a nonmetal. *Examples:* arsenic; polonium.

meter (m) The SI unit of length. See also Appendix 1B.

micelle A compact, often nearly spherical cluster of oriented detergent (surfactant) molecules.

Michaelis constant (K_M) A constant in the rate law for the *Michaelis–Menten mechanism*.

Michaelis–Menten mechanism A model of enzyme catalysis in which the enzyme and its substrate reach a rapid *pre-equilibrium* with the bound substrate–enzyme complex.

microporous catalyst A catalyst with an open, porous structure. *Example:* a *zeolite*.

microscopic level A level of description that refers to the very small, such as atoms.

microstate A permissible instantaneous arrangement of molecules in a sample (in the context of statistical thermodynamics and the statistical definition of entropy).

microwaves Electromagnetic radiation with wavelengths close to 1 cm.

millimeter of mercury (mmHg) The pressure exerted by a column of mercury of height 1 mm (at 15°C and in a standard gravitational field).

minerals Substances that are mined; more generally, inorganic substances.

minimum-boiling azeotrope See *azeotrope*.

mixture A type of matter that consists of more than one substance and can be separated into its components by making use of the different physical properties of the substances present.

model A simplified description of nature.

moderator A substance that slows neutrons. *Examples:* graphite; heavy water.

molality The amount of solute (in moles) per kilogram of solvent.

molar Refers to the quantity per mole. *Examples: molar mass,* the mass per mole; *molar volume,* the volume per mole. (*Molar concentration* and some related quantities are exceptions.)

molar absorption coefficient The constant of proportionality between the absorbance of a sample and the product of its molar concentration and path length. See also *Beer's law*.

molar concentration ([J]) The amount (in moles) of solute per liter of solution.

molar heat capacity (C_m) The heat capacity per mole of substance.

molarity ([J]) Molar concentration.

molar mass (1) The mass per mole of atoms of an element. (2) The mass per mole of molecules of a molecular compound. (3) The mass per mole of formula units of an ionic compound.

molar solubility (s) The numerical value of the molar concentration of a saturated solution of a substance.

molar volume The volume of a sample divided by the amount (in moles) of atoms or molecules that it contains.

mole (mol) The SI unit of chemical amount. See also Appendix 1B.

molecular biology The study of the functions of living organisms in terms of their molecular composition.

molecular compound A compound that consists of molecules. *Examples:* water; sulfur hexafluoride; benzoic acid.

molecular formula A combination of chemical symbols and subscripts showing the actual numbers of atoms of each element present in a molecule. *Examples:* H_2O; SF_6; C_6H_5COOH.

molecular hydride See *hydride*.

molecularity The number of reactant molecules (or free atoms) taking part in an *elementary reaction*. See also *bimolecular reaction; termolecular reaction; unimolecular reaction*.

molecular magnet A group of several d-block metal atoms bonded to nonmetal atoms such as carbon, hydrogen, and oxygen and which can respond to a magnetic field.

molecular orbital A wavefunction that spreads throughout a molecule and gives the probability (through its square) that an electron will be found at each location.

molecular orbital energy-level diagram A portrayal of the relative energies of the molecular orbitals in a molecule.

molecular orbital theory The description of molecular structure in which electrons occupy orbitals that spread throughout a molecule.

molecular solid A solid consisting of a collection of individual molecules held together by intermolecular forces. *Examples:* glucose; aspirin; sulfur.

molecular weight The numerical value of the *molar mass* of a molecular compound.

molecule (1) The smallest particle of a compound that possesses the chemical properties of the compound. (2) A definite, distinct, electrically neutral group of bonded atoms. *Examples:* H_2; NH_3; CH_3COOH.

mole fraction (x) The amount of particles (molecules, atoms, or ions) of a substance in a mixture expressed as a fraction of the total amount of particles in the mixture.

mole ratio The stoichiometric relation between two species in a chemical reaction written as a conversion factor. *Example:* (2 mol H_2)/(1 mol O_2) in the reaction $2\,H_2(g) + O_2(g) \rightarrow 2\,H_2O(l)$.

momentum (p) See *linear momentum*.

monatomic ion An ion formed from a single atom. *Examples:* Na^+; Cl^-.

Mond process The purification of nickel by the formation and decomposition of nickel carbonyl.

monomer A small molecule from which a polymer is formed. *Examples:* $CH_2{=}CH_2$ for polyethylene; $NH_2(CH_2)_6NH_2$ for nylon.

monoprotic acid A Brønsted acid with one acidic hydrogen atom. *Example:* CH_3COOH.

monosaccharide An individual unit from which carbohydrates are considered to be composed. *Example:* $C_6H_{12}O_6$, glucose.

multiple bond A double or triple bond between two atoms.

nanomaterials Materials composed of nanoparticles or regular arrays of molecules or atoms such as nanotubes.

nanoparticles Particles that range in size from about 1 to 100 nm and can be manufactured and manipulated at the molecular level.

nanoscience The study of materials at the nanometer scale. These materials are larger than single atoms, but too small to exhibit most bulk properties.

nanotechnology The study and manipulation of matter at the atomic level (nanometer scale).

natural abundance (of an isotope) The abundance of an isotope in a sample of a naturally occurring material.

natural antilogarithm See *exponential*.

natural logarithm See *logarithm*.

naturally occurring Found in nature without needing to be synthesized.

natural product An organic substance that occurs naturally in the environment.

negative deviation (from Raoult's law) The tendency of a nonideal solution to have a vapor pressure lower than predicted by Raoult's law.

nematic phase A liquid-crystal phase in which rod-shaped molecules have axes arranged parallel to each other but staggered with respect to one another in other directions.

Nernst equation The equation expressing the emf of an electrochemical cell in terms of the concentrations of the reagents taking part in the cell reaction; $E_{cell} = E_{cell}° - (RT/nF) \ln Q$.

net ionic equation The equation showing the net change in a chemical reaction, obtained by canceling the spectator ions in a complete ionic equation. *Example:* $Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$.

network solid A solid consisting of atoms linked together covalently throughout its extent. *Examples:* diamond; silica.

neutralization reaction The reaction of an acid with a base to form a salt. *Example:* $HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$.

neutron (n) An electrically neutral subatomic particle found in the nucleus of an atom; it has approximately the same mass as a proton.

neutron emission A nuclear decay process in which a neutron is emitted. In neutron emission, the mass number decreases by 1, but the charge number remains the same.

neutron-induced transmutation The conversion of one nucleus into another by the impact of a neutron. *Example:* ${}^{58}_{26}Fe + 2\,{}^{1}_{0}n \longrightarrow {}^{60}_{27}Co + {}^{0}_{-1}e$.

neutron-rich nucleus A nucleus with such a high proportion of neutrons that it lies above the *band of stability.*

NO_x An oxide, or mixture of oxides, of nitrogen, typically in atmospheric chemistry.

noble gas A member of Group 18/VIII of the periodic table (the helium family).

nodal plane A plane on which an electron in an atom or molecule will not be found.

node A point or surface on which a wavefunction passes through zero.

nomenclature See *chemical nomenclature.*

nonaqueous solution A solution in which the solvent is not water. *Example:* sulfur in carbon disulfide.

nonbonding orbital A valence-shell atomic orbital that has not been used to form a bond to another atom.

nonelectrolyte A substance that dissolves to give a solution that does not conduct electricity. *Example:* sucrose.

nonelectrolyte solution A solution of a nonelectrolyte.

nonexpansion work (w_e) See *work.*

nonferrous alloy An alloy based on metals other than iron. *Examples:* brass, bronze.

nonideal solution A solution that does not obey Raoult's law. Compare with *ideal solution.*

nonlabile Refers to a species that survives for a long period, even if it is thermodynamically unstable.

nonmetal A substance that does not conduct electricity and is neither malleable nor ductile. *Examples:* all gases; phosphorus; sodium chloride.

nonpolar bond (1) A covalent bond between two atoms that have zero partial charges. (2) A covalent bond between two atoms with the same or nearly the same electronegativity.

nonpolar molecule A molecule with zero electric dipole moment.

normal boiling point (T_b) (1) The boiling temperature when the pressure is 1 atm. (2) The temperature at which the vapor pressure of a liquid is 1 atm.

normal form The form of a substance under typical everyday conditions (for instance, close to 1 atm, 25°C).

normal freezing point (T_f) The temperature at which a liquid freezes at 1 atm.

normal melting point (T_f) The melting point of a substance at a pressure of 1 atm.

***n*s-orbital** An atomic orbital with principal quantum number n and $l = 0$.

n-type semiconductor See *semiconductor.*

nuclear atom The structure of the atom proposed by Rutherford: a central, small, very dense, positively charged nucleus surrounded by electrons.

nuclear binding energy (E_{bind}) The energy released when Z protons and $A - Z$ neutrons come together to form a nucleus with atomic number Z and mass number A. The greater the binding energy per nucleon, the lower the energy of the nucleus.

nuclear chemistry The study of the chemical consequences of nuclear reactions.

nuclear decay The spontaneous partial breakup of a nucleus (including its fission). Nuclear decay is also referred to as *nuclear disintegration. Example:* ${}^{226}_{88}Ra \longrightarrow {}^{222}_{86}Rn + {}^{4}_{2}\alpha$.

nuclear equation A summary of the changes in a nuclear reaction, written in a form resembling a chemical equation.

nuclear fission See *fission.*

nuclear fusion See *fusion.*

nuclear model A model of the atom in which the electrons surround a minute central nucleus.

nuclear reaction A change that a nucleus undergoes (such as a nuclear transmutation).

nuclear reactor A device for achieving controlled self-sustaining nuclear fission.

nuclear transmutation The conversion of one element into another. *Example:* ${}^{12}_{6}C + {}^{4}_{2}\alpha \longrightarrow {}^{16}_{8}O + \gamma$.

nucleic acid (1) The product of a condensation of nucleotides. (2) A molecule containing an organism's genetic information.

nucleon A proton or a neutron; thus, either of the two principal components of a nucleus.

nucleophile A reactant that seeks out centers of positive charge in a molecule. *Examples:* H_2O, OH^-.

nucleophilic substitition Substitution that results from attack by a nucleophile. *Examples:* hydrolysis of haloalkanes, $CH_3Br + H_2O \longrightarrow CH_3OH + HBr$.

nucleoside A combination of an organic base and a ribose or deoxyribose molecule.

nucleosynthesis The formation of an element.

nucleotide A nucleoside with a phosphate group attached to the carbohydrate ring; one of the units from which nucleic acids are made.

nucleus The small, positively charged particle at the center of an atom that is responsible for most of its mass.

nuclide A specific nucleus. *Examples:* ${}^{1}_{1}H$; ${}^{16}_{8}O$

nutritional calorie (Cal) A unit used in food science to measure the caloric value of food; 1 nutritional calorie = 1 kilocalorie.

occupy Have the characteristics of the wavefunction of a specified state; to be in a specified state.

octahedral complex A complex in which six ligands are arranged at the corners of a regular octahedron, with a metal atom or ion at the center. *Example:* $[Fe(CN)_6]^{4-}$.

octahedral hole A cavity in a (usually close packed) crystal lattice formed from six spheres at the corners of a regular octahedron.

octet An ns^2np^6 valence electron configuration.

octet rule When atoms form bonds, they proceed as far as possible toward completing their octets by sharing electron pairs.

oligopeptide A short chain of amino acids connected by amide (peptide) bonds.

one-component phase diagram See *phase diagram*.

open system See *system*.

optical activity The ability of a substance to rotate the plane of polarized light passing through it.

optical isomers Isomers that are related like an object and its mirror image. *Optical isomerism* is the existence of optical isomers. *Optical isomerism* is a type of *stereoisomerism*.

orbital See *atomic orbital* and *molecular orbital*.

orbital angular momentum A measure of the rate of rotation.

orbital angular momentum quantum number (l) The quantum number that specifies the subshell of a given shell in an atom and determines the shapes of the orbitals in the subshell; $l = 0, 1, 2, \ldots, n - 1$. *Examples:* $l = 0$ for the s-subshell; $l = 1$ for the p-subshell. (The quantum number l also specifies the magnitude of the angular momentum of the electron around the nucleus.)

order of reaction The power to which the concentration of a single substance is raised in a rate law. *Example:* if the rate $= k[SO_2][SO_3]^{-1/2}$, then the reaction is first order in SO_2, and of order $-\frac{1}{2}$ in SO_3.

ore The natural mineral source of a metal. *Example:* Fe_2O_3, hematite, an iron ore.

organic chemistry The branch of chemistry that deals with *organic compounds*.

organic compound A compound containing the element carbon and usually hydrogen. (The carbonates are normally excluded.)

organometallic compound A compound that contains a metal–carbon bond. *Example:* $Ni(CO)_4$.(Complexes of CN^- are normally excluded.)

oscillating Varying in a periodic manner with time.

osmometry The determination of the molar mass of a solute from osmotic pressure measurements.

osmosis The tendency of a solvent to flow through a semipermeable membrane into a more concentrated solution (a colligative property).

osmotic pressure (Π, pi) The pressure needed to stop the flow of solvent through a semipermeable membrane. See also *osmosis*.

overall formation constant See *formation constant*.

overall order The sum of the powers to which individual concentrations are raised in the rate law of a reaction. *Example:* If rate $= k[SO_2][SO_3]^{-1/2}$, then the overall order is $\frac{1}{2}$.

overall reaction The net outcome of a sequence of reactions.

overlap The merging of orbitals belonging to different atoms of a molecule.

overpotential The additional potential difference that must be applied beyond the cell potential to cause appreciable electrolysis.

oxidation (1) Combination with oxygen. (2) A reaction in which an atom, ion, or molecule loses an electron. (3) A half-reaction in which the oxidation number of an element is increased. *Examples:* (1, 2) $2\,Mg(s) + O_2(g) \longrightarrow 2\,MgO(s)$; (2, 3) $Mg(s) \longrightarrow Mg^{2+}(s) + 2\,e^-$.

oxidation number The effective charge on an atom in a compound, calculated according to a set of rules (see Toolbox K.1). An increase in oxidation number corresponds to oxidation; a decrease corresponds to reduction.

oxidation–reduction reaction See *redox reaction*.

oxidation state The actual condition of a species with a specified oxidation number.

oxidizing agent A species that removes electrons from a species being oxidized (and is itself reduced) in a redox reaction. *Examples:* O_2; O_3; MnO_4^-; Fe^{3+}.

oxoacid An acid that contains oxygen. *Examples:* H_2CO_3; HNO_3; HNO_2; HClO.

oxoanion An anion of an oxoacid. *Examples:* HCO_3^-; CO_3^{2-}.

paired electrons Two electrons with opposed spins (↑↓).

parallel spins Electrons with spins aligned in the same direction (↑↑).

paramagnetic substance See *paramagnetism*.

paramagnetism The tendency to be pulled into a magnetic field; a paramagnetic substance is composed of atoms or molecules with unpaired electrons. *Examples:* O_2; $[Fe(CN)_6]^{3-}$.

parent nucleus In a nuclear reaction, the nucleus that undergoes disintegration or transmutation.

partial charge A charge arising from small shifts in the distributions of electrons. A partial charge can be either *positive* (δ+) or *negative* (δ–).

partial pressure (P_X) The pressure that a gas (X) in a mixture would exert if it alone occupied the container.

particle in a box A particle confined between rigid walls.

parts per million (ppm) (1) The ratio of the mass of a solute to the mass of the solution, multiplied by 10^6. (2) The *mass percentage composition* multiplied by 10^4. (*Parts per billion*, ppb, the mass ratio multiplied by 10^9, also may be used.)

pascal (Pa) The SI unit of pressure: $1\ Pa = 1\ kg\cdot m^{-1}\cdot s^{-2}$. See also Appendix 1B.

passivation Protection from further reaction by a surface film. *Example:* aluminum in air.

Pauli exclusion principle See *exclusion principle*.

p-electron An electron in a p-orbital.

penetration The possibility that an s-electron may be found inside the inner shells of an atom and hence close to the nucleus.

peptide A molecule formed by a condensation reaction between amino acids; often described in terms of the number of units, for example, *dipeptide, oligopeptide, polypeptide.*

peptide bond The —CONH— group.

percentage composition See *mass percentage composition; volume percentage composition.*

percentage deprotonation The fraction of a weak acid, expressed as a percentage, that is present as its conjugate base in a solution.

percentage ionization The fraction of molecules of a substance, expressed as a percentage, that is present as ions.

percentage protonated The fraction of a base, expressed as a percentage, that is present as its conjugate acid in a solution.

percentage yield The percentage of the theoretical yield of a product achieved in practice.

period A horizontal row in the periodic table; the number of the period is equal to the principal quantum number of the valence shell of the atoms.

periodic table A chart in which the elements are arranged in order of atomic number and divided into groups and periods in a manner that shows the relationships between the properties of the elements.

pH The negative logarithm of the hydronium ion molarity in a solution: $pH = -\log[H_3O^+]$. A $pH < 7$ indicates an acidic solution; $pH = 7$, a neutral solution; and $pH > 7$, a basic solution.

phase A specific physical state of matter. A substance may exist in solid, liquid, and gaseous phases and, in certain cases, in more than one solid or liquid phase. *Examples:* white and gray tin are two solid phases of tin; ice, liquid, and vapor are three phases of water.

phase boundary (1) A line separating two areas in a phase diagram; the points on a phase boundary represent the conditions at which the two adjoining phases are in dynamic equilibrium. (2) The surface between two phases.

phase diagram A summary in graphical form of the conditions of temperature and pressure at which the various solid, liquid, and gaseous phases of a substance exist. A *one-component phase diagram* is a phase diagram for a single substance.

phase transition The conversion of a substance from one phase into another phase. *Examples:* vaporization; white tin $\longrightarrow$ gray tin.

pH curve A graph of the pH of a reaction mixture against volume of titrant added in an acid–base titration.

phenol An organic compound in which a hydroxyl group is attached directly to an aromatic ring (Ar—OH). *Example:* C_6H_5OH, phenol.

pH meter An electronic device used to measure the pH of a solution.

phosphor A phosphorescent material that emits light after excitation to higher energy states.

phosphorescence Long-lasting *luminescence.*

photochemical reaction A reaction caused by light. *Example:* $H_2(g) + Cl_2(g) \xrightarrow{h\nu} 2\,HCl(g)$.

photoelectric effect The emission of electrons from the surface of a metal when electromagnetic radiation strikes it.

photon A particle-like packet of electromagnetic radiation. The energy of a photon of frequency ν is $E = h\nu$.

physical change A change in which the identity of the substance does not change and only its physical properties are different. *Example:* freezing.

physical chemistry The study of the principles of chemistry.

physical equilibrium A state in which two or more phases of a substance coexist without a tendency to change. *Example:* ice and water at 0°C and 1 atm.

physical property A characteristic that we observe or measure without changing the identity of the substance.

physical state The condition of being a solid, a liquid, or a gas at a particular temperature.

pi (π) bond A bond formed by the side-to-side overlap of two p-orbitals.

piezoelectric Having the property of becoming electrically charged when mechanically distorted. *Example:* $BaTiO_3$.

pi (π) orbital A molecular orbital that has one nodal plane cutting through the internuclear axis.

pipet A narrow tube, sometimes with a central bulb, calibrated to deliver a specified volume.

pK_a and pK_b The negative logarithms of the acidity and basicity constants: $pK = -\log K$. The larger the value of pK_a or pK_b, the weaker the acid or base, respectively.

Planck's constant (h) A fundamental constant of nature with the value 6.626×10^{-34} J·s.

plasma (1) An ionized gas. (2) In biology, the colorless component of blood in which the red and white blood cells are dispersed.

p–n junction An interface between a p-type and an n-type semiconductor.

pOH The negative logarithm of the hydroxide ion molarity in a solution; $pOH = -\log[OH^-]$.

poison Verb: To inactivate a catalyst.

polar covalent bond A covalent bond between atoms that have partial electric charges. *Examples:* H—Cl; O—S.

polarizability (α) The ease with which the electron cloud of a molecule can be distorted.

polarizable An easily polarized species.

polarize To distort the electron cloud of an atom or ion.

polarized light Plane-polarized light is light in which the wave motion occurs in a single plane.

polarizing power The ability of an ion to polarize a neighboring atom or ion.

polar molecule A molecule with a nonzero electric dipole moment. *Examples:* HCl; NH_3.

polyamide A polymer in which the monomers are linked by amide bonds formed by condensation.

polyatomic ion An ion in which more than two atoms are linked by covalent bonds. *Examples:* NH_4^+; NO_3^-; SiF_6^{2-}.

polyatomic molecule A molecule that consists of more than two atoms. *Examples:* O_3; $C_{12}H_{22}O_{11}$.

polycyclic compound An aromatic compound containing two or more benzene rings that share two neighboring carbon atoms. *Example:* naphthalene.

polydentate ligand A ligand that can attach at several binding sites.

polyester A polymer in which the monomers are linked by ester groups formed by condensation polymerization.
polymer A substance with large molecules consisting of chains of covalently linked repeating units formed from small molecules known as *monomers*. *Examples:* polyethylene; nylon. See also *copolymer*.
polymerization The formation of a *polymer* from its *monomers*.
polynucleotide A polymer built from nucleotide units. *Examples:* DNA; RNA.
polypeptide A polymer formed by the condensation of amino acids.
polyprotic acid or base A Brønsted acid or base that can donate or accept more than one proton. (A polyprotic acid is sometimes called a polybasic acid.) *Examples:* H_3PO_4, triprotic acid; N_2H_4, diprotic base.
polysaccharide A chain of many saccharide units, such as glucose, linked together. *Examples:* cellulose; amylose.
p-orbital See *atomic orbital*.
positional disorder Disorderly locations of molecules; a contribution to the entropy.
positive ion An ion formed by loss of one or more electrons from an atom or molecule; a *cation*.
positron A fundamental particle with the same mass as an electron but with opposite charge.
positron emission A mode of radioactive decay in which a nucleus emits a positron.
potential difference An electrical potential difference between two points is a measure of the work that must be done to move an electric charge from one point to the other. Potential difference is measured in volts, V, and is commonly called the *voltage*.
potential energy (E_p) The energy arising from position. *Example:* the Coulomb potential energy of a charge is inversely proportional to its distance from another charge.
potential energy surface A surface showing the variation of the potential energy with the relative location of the atoms in a polyatomic cluster of atoms (as in a collision between a diatomic molecule and an atom).
power The rate of supply of energy. The SI unit of power is the watt, W ($1\ W = 1\ J \cdot s^{-1}$). See also Appendix 1B.
precipitate The solid formed in a precipitation reaction.
precipitation The process in which a solute comes out of solution rapidly as a finely divided powder, called a *precipitate*. A precipitation reaction is a reaction in which a precipitate is formed when two solutions are mixed. *Example:* $KBr(aq) + AgNO_3(aq) \longrightarrow KNO_3(aq) + AgBr(s)$.
precise measurements (1) Measurements with a large number of significant figures. (2) A series of measurements with small random error and hence in close mutual agreement.
precision Freedom from random error. Compare with *accuracy*.
pre-equilibrium condition A pre-equilibrium arises (or is assumed) when an intermediate is formed in a rapid equilibrium reaction prior to a slow step in a reaction mechanism.
pre-exponential factor (A) The constant obtained from the y intercept in an Arrhenius plot.
pressure (P) Force divided by the area to which it is applied.
primary alcohol See *alcohol*.
primary cell A *galvanic cell* that produces electricity from chemicals sealed within it at the time of manufacture. It cannot be recharged.
primary pollutant A pollutant directly introduced into the environment. *Example:* SO_2.
primary structure The sequence of amino acids in the polypeptide chain of a protein.
primitive cubic structure A structure in which the unit cell consists of spheres (representing atoms or ions) at the corners of a cube.
principal quantum number (n) The quantum number that specifies the energy of an electron in a hydrogen atom and labels the shells of the atom.
probability density (of a particle) A function that, when multiplied by the volume of the region, gives the probability that the particle will be found in that region of space. See also *Born interpretation*.
product A species formed in a chemical reaction.
promotion (of an electron) The conceptual excitation of an electron to an orbital of higher energy in the description of bond formation.
propagation A series of steps in a chain reaction in which one chain carrier reacts with a reactant molecule to produce another carrier. *Examples:* $Br\cdot + H_2 \longrightarrow HBr + H\cdot$; $H\cdot + Br_2 \longrightarrow HBr + Br\cdot$. See also *chain reaction*.
property A characteristic of matter. *Examples:* vapor pressure; color; density; temperature. See also *chemical property; physical property*.
protective oxide An oxide that protects a metal from further oxidation. *Example:* aluminum oxide.
proton (p) A positively charged subatomic particle found in the nucleus of an atom.
protonation Proton transfer to a Brønsted base. *Example:* $H_3O^+(aq) + HS^-(s) \longrightarrow H_2S(g) + H_2O(l)$.
proton emission A nuclear decay process in which a proton is emitted. In proton emission, the mass and charge numbers of the nucleus both decrease by 1.
proton-rich nucleus A nucleus that has a low proportion of neutrons and lies below the *band of stability*.
proton transfer equilibrium The equilibrium involving the transfer of a hydrogen ion between an acid and a base.
proton transfer reaction See *proton transfer equilibrium*.
pseudo-first-order reaction A reaction with a rate law that is effectively first order because all but one species have virtually constant concentrations.
p-type semiconductor See *semiconductor*.
pX The quantity $-\log X$. *Example:* $pOH = -\log [OH^-]$.
pyrometallurgical process The extraction of metals by using reactions at high temperatures. *Example:* $Fe_2O_3(s) + 3\ CO(g) \xrightarrow{\Delta} 2\ Fe(l) + 3\ CO_2(g)$.

quadratic equation An equation of the form $ax^2 + bx + c = 0$. See also Appendix 1E.
qualitative A nonnumerical description of the properties of a substance, system, or process. See *qualitative analysis*.
qualitative analysis The identification of the substances present in a sample.
quanta The plural of *quantum*.

quantitative A numerical description of the properties of a substance, system, or process. See *quantitative analysis*.

quantitative analysis The determination of the amount of each substance present in a sample.

quantization The restriction of a property to certain values. *Examples:* the quantization of energy and angular momentum.

quantum A packet of energy.

quantum dot A small three-dimensional cluster of semiconducting materials. *Example:* 10 to 10^5 atoms of Cd and Se (as cadmium selenide, CdSe).

quantum mechanics The description of matter that takes into account the wave–particle duality of matter and the fact that the energy of an object may be changed only in discrete steps.

quantum number An integer (sometimes, a half-integer) that labels a wavefunction and specifies the value of a property. *Example:* principal quantum number, *n*.

quaternary ammonium ion An ion of the form NR_4^+, where R denotes hydrogen or an alkyl group (the four groups may be different).

quaternary structure The manner in which neighboring polypeptide units stack together to form a protein molecule.

racemic mixture A mixture containing equal amounts of two enantiomers.

rad A (non-SI) unit of *absorbed dose* of radiation; 1 rad corresponds to an energy deposit of 10^{-2} J·kg^{-1}. See also *gray*.

radial distribution function The function that gives the probability that an electron in an atom will be found at a particular radius regardless of the direction.

radial wavefunction ($R(r)$) The radial part of a wavefunction, particularly the radial component of the wavefunctions of the hydrogen atom; the probability amplitude of an electron as a function of distance from the nucleus.

radiation absorbed dose (rad) The amount of radiation that deposits 10^{-2} J of energy per kilogram of tissue.

radical An atom, molecule, or ion with at least one unpaired electron. *Examples:* ·NO; ·O·; $\cdot CH_3$.

radical chain reaction A chain reaction propagated by radicals.

radical polymerization A polymerization procedure that utilizes a radical chain reaction.

radical scavenger A substance that reacts with radicals and inhibits a chain reaction.

radioactive A nucleus is radioactive if it can change its structure spontaneously and emit radiation.

radioactive series A step-by-step nuclear decay path in which α and β particles are successively ejected and which terminates at a stable nuclide (often a nuclide of lead).

radioactivity The spontaneous emission of radiation by nuclei. Such nuclei are radioactive.

radiocarbon dating *Isotopic dating* based specifically on the use of carbon-14.

radioisotope A radioactive isotope.

radius ratio The ratio of the radius of the smaller ion in an ionic solid to the radius of the larger ion. The radius ratio controls which crystal structure is adopted by a simple ionic solid.

random copolymer See *copolymer*.

random error An error that varies randomly from measurement to measurement, sometimes giving a high value and sometimes a low one.

Raoult's law The vapor pressure of a liquid solution of a nonvolatile solute is directly proportional to the mole fraction of the solvent in the solution: $P = x_{\text{solvent}}P_{\text{pure}}$, where P_{pure} is the vapor pressure of the pure solvent.

rate The change in a property divided by the time interval.

rate constant (k) The constant of proportionality in a rate law.

rate-determining step The elementary reaction that governs the rate of the overall reaction. *Example:* the step $O + O_3 \longrightarrow O_2 + O_2$ in the decomposition of ozone.

rate law An equation expressing the instantaneous reaction rate in terms of the concentrations, at any instant, of the substances taking part in the reaction. *Example:* rate = $k[NO_2]^2$.

rate of reaction See *instantaneous rate; reaction rate*.

reactant A species acting as a starting material in a chemical reaction; a reagent taking part in a specified reaction.

reaction enthalpy (ΔH) The change of enthalpy for the reaction as expressed by the chemical equation, with stoichiometric coefficients interpreted as the amounts in moles. *Example:* $CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(l)$, $\Delta H = -890$ kJ.

reaction Gibbs free energy (ΔG) The change in Gibbs free energy for the reaction as expressed by the chemical equation with stoichiometric coefficients interpreted as amounts in moles.

reaction intermediate A species that is produced and consumed during a reaction but does not appear in the overall chemical equation.

reaction mechanism The pathway that is proposed for an overall reaction and accounts for the experimental rate law.

reaction order See *order of reaction*.

reaction profile The variation in potential energy as two reactants meet, form an activated complex, and separate as products.

reaction quotient (Q) The ratio of the activities of the products to those of the reactants, each raised to a power equal to the stoichiometric coefficient (as in the definition of the equilibrium constant, but at an arbitrary stage of a reaction). *Example:* for $N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g)$, $Q = (P_{NH_3})^2/P_{N_2}(P_{H_2})^3$.

reaction rate The unique rate of a chemical reaction calculated by dividing the change in concentration of a substance by the interval during which the change takes place and by taking into account the stoichiometric coefficient of the substance. See also *unique average reaction rate*.

reaction sequence A series of reactions in which the products of one reaction take part as reactants in the next. *Example:* $2\,C(s) + O_2(g) \longrightarrow 2\,CO(g)$, followed by $2\,CO(g) + O_2(g) \longrightarrow 2\,CO_2(g)$.

reaction stoichiometry The quantitative relation between the amounts of reactants consumed and those of products formed in chemical reactions as expressed by the balanced chemical equation for the reaction.

reagent A substance or a solution that reacts with other substances.

real gas An actual gas; a gas that differs from an ideal gas in its behavior.

recrystallization Purification by repeated dissolving and crystallization.

redox couple The oxidized and reduced forms of a substance taking part in a reduction or oxidation half-reaction. The notation is oxidized species/reduced species. *Example:* H^+/H_2.

redox indicator See *indicator.*

redox reaction A reaction in which oxidation and reduction take place. *Example:* $S(s) + 3\,F_2(g) \rightarrow SF_6(g)$.

redox titration See *titration.*

reducing agent The species that supplies electrons to a substance being reduced (and is itself oxidized) in a redox reaction. *Examples:* H_2; H_2S; SO_3^{2-}.

reduction (1) The removal of oxygen from, or the addition of hydrogen to, a compound. (2) A reaction in which an atom, ion, or molecule gains an electron. (3) A half-reaction in which the oxidation number of an element is decreased. *Example:* $Cl_2(g) + 2\,e^- \rightarrow 2\,Cl^-(aq)$.

re-forming reaction A reaction in which a hydrocarbon is converted into carbon monoxide and hydrogen over a nickel catalyst.

refractory Able to withstand high temperatures.

relative biological effectiveness (Q) A factor used when assessing the damage caused by a given dose of radiation.

rem See *roentgen equivalent man.*

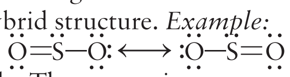
repeating unit The combination of atoms in a polymer that repeats over and over again in the polymer chain.

residual entropy The nonzero entropy at $T = 0$ in certain systems, which is due to a surviving disorder in the orientation of molecules.

residue (biochemical) An amino acid in a polypeptide chain.

resistance (electrical) A measure of the ability of matter to conduct electricity: the lower the resistance, the better it conducts.

resonance A blending of Lewis structures into a single composite, hybrid structure. *Example:*



resonance hybrid The composite structure that results from resonance.

reverse osmosis The passage of solvent out of a solution when a pressure greater than the osmotic pressure is applied on the solution side of a semipermeable membrane.

reversible isothermal expansion Expansion at constant temperature against an external pressure matched to the pressure of the system.

reversible process A process that can be reversed by an infinitesimal change in a variable.

rock-salt structure A crystal structure the same as that of a mineral form of sodium chloride.

roentgen equivalent man (rem) The (non-SI) unit for reporting *dose equivalent*. See also *sievert*.

root mean square speed (v_{rms}) The square root of the average value of the squares of the speeds of the molecules in a sample.

roots (of an equation) The solutions of the equation $f(x) = 0$. See also Appendix 1E.

rotational kinetic energy See *kinetic energy.*

rounding off The adjustment of a numerical result to the correct number of significant figures.

Rydberg constant ($\mathcal{R}$) The constant in the formula for the frequencies of the lines in the spectrum of atomic hydrogen; $\mathcal{R} = 3.290 \times 10^{15}$ Hz.

sacrificial anode A metal electrode that is allowed to decay in order to protect a metallic artifact. See *cathodic protection.*

saline hydride See *hydride.*

salt (1) An ionic compound. (2) The ionic product of the reaction between an acid and a base. *Examples:* NaCl; K_2SO_4.

salt bridge An inverted U-shaped tube containing a concentrated salt (potassium chloride or potassium nitrate) in a gel that acts as an electrolyte and provides a conducting path between two compartments of an electrochemical cell.

sample A representative part of a whole.

saturated Unable to take up further material.

saturated hydrocarbon A hydrocarbon with no carbon–carbon multiple bonds. *Example:* CH_3CH_3.

saturated solution A solution in which the dissolved and undissolved solute are in dynamic equilibrium.

Schrödinger equation An equation for calculating the wavefunction of a particle, especially for an electron in an atom or molecule. See also *wavefunction.*

science The systematically collected and organized body of knowledge based on experiment, observation, and careful reasoning.

scientific method A set of procedures employed to develop a scientific understanding of nature.

scientific notation The expression of numbers in the form $n.nnn \ldots \times 10^a$.

scintillation counter A device for detecting and measuring radioactivity that makes use of the fact that certain substances give a flash of light when they are exposed to radiation.

sea of instability A region in a graph of mass number against atomic number corresponding to unstable nuclei that decay spontaneously with the emission of radiation. See also *band of stability.*

second (s) The SI unit of time. See also Appendix 1B.

secondary alcohol See *alcohol.*

secondary cell A *galvanic cell* that must be charged (or recharged) by using an externally supplied current before it can be used.

secondary pollutant A pollutant formed by the chemical reaction of another species in the environment. *Example:* SO_3 from the oxidation of SO_2.

secondary structure The manner in which a polypeptide chain is coiled. *Examples:* α helix; β sheet.

second derivative (d^2y/dx^2) A measure of the curvature of a function. See also Appendix 1F.

second ionization energy (I_2) The energy needed to remove an electron from a singly charged gas-phase cation. *Example:* $Cu^+(g) \rightarrow Cu^{2+}(g) + e^-(g)$, $I_2 = 1958\ kJ\cdot mol^{-1}$.

second law of thermodynamics A spontaneous change is accompanied by an increase in the total entropy of the system and its surroundings.

second-order reaction (1) A reaction with a rate that is proportional to the square of the molar concentration of a reactant. (2) A reaction with an overall order of 2.

second virial coefficient (B) See *virial equation*.
selective precipitation The precipitation of one compound in the presence of other, more soluble compounds.
self-sustaining fission Induced nuclear fission that, once it is initiated, can continue even if the supply of neutrons from outside is discontinued.
semiconductor An *electronic conductor* with a resistance that decreases as the temperature is raised. In an *n-type semiconductor,* the current is carried by electrons in a largely empty band; in a *p-type semiconductor,* the conduction is a result of electrons missing from otherwise filled bands.
semi-empirical method The calculation of molecular structure that draws on experimental information to simplify the procedure. Compare with *ab initio method*.
semipermeable membrane A membrane that allows only certain types of molecules or ions to pass.
sequester Form a complex between a cation and a bulky molecule or ion that enwraps the central ion. *Example:* Ca^{2+} and $O_3POPO_2OPO_3{}^{3-}$.
series (in spectroscopy) A family of spectral lines arising from transitions that have one state in common. *Example:* the Balmer series in the spectrum of atomic hydrogen.
shell All the orbitals of a given principal quantum number. *Example:* the single 2s- and three 2p-orbitals of the shell with $n = 2$.
shielding The repulsion experienced by an electron in an atom that arises from the other electrons present and opposes the attraction exerted by the nucleus.
shift reaction A reaction between carbon monoxide and water: $CO(g) + H_2O(g) \longrightarrow CO_2(g) + H_2(g)$; the reaction is used in the manufacture of hydrogen.
short-range order Atoms or molecules lying in a regular arrangement that does not extend very far past their nearest neighbors.
SI (Système International) The International System of units; a collection of definitions of units and symbols and their deployment. It is an extension and rationalization of the metric system. See also Appendix 1B.
side chain A hydrocarbon substituent on a hydrocarbon chain.
sievert (Sv) The SI unit of dose equivalent: $1\ Sv = 1\ J \cdot kg^{-1}$.
sigma (σ) bond Two electrons in a cylindrically symmetrical cloud between two atoms.
sigma (σ) orbital A molecular orbital that has no nodal plane containing the internuclear axis.
significant figures (sf, in a measurement) The digits in the measurement, up to and including the first uncertain digit in scientific notation. *Example:* 0.0260 mL (that is, 2.60×10^{-2} mL), a measurement with three significant figures (3 sf).
single bond A shared electron pair.
skeletal equation An unbalanced equation that summarizes the qualitative information about the reaction. *Example:* $H_2 + O_2 \rightarrow H_2O$.
slip plane A layer of atoms in a solid that may slide relatively easily across a neighboring layer.
slope (of graph) The gradient of a graph. See also Appendix 1E.
smectic phase A liquid-crystal phase in which molecules lie parallel to one another and form layers.
soft matter Matter that deforms readily when subjected to an applied force.
sol A colloidal dispersion of solid particles in a liquid.
solid A rigid form of matter that maintains the same shape whatever the shape of its container.
solid electrolyte A solid ionic conductor.
solid emulsion A colloidal dispersion of a liquid in a solid. *Example:* butter, an emulsion of water in butterfat.
solid solution A solid homogeneous mixture of two or more substances.
solubility The concentration of a saturated solution of a substance.
solubility constant See *solubility product*.
solubility product (K_{sp}) The product of ionic molar concentrations in a saturated solution; the dissolution equilibrium constant. *Example:* $Hg_2Cl_2(s) \rightleftharpoons Hg_2{}^{2+}(aq) + 2\ Cl^-(aq)$, $K_{sp} = [Hg_2{}^{2+}][Cl^-]^2$.
solubility rules A summary of the solubility pattern of a range of common compounds in water. See also Table I.1.
soluble substance A substance that dissolves to a significant extent in a specified solvent. When the solvent is not specified, water is generally meant.
solute A dissolved substance.
solution A homogeneous mixture. See also *solute; solvent*.
solvated Surrounded by and linked to solvent molecules. *Hydration* is the special case in which the solvent is water.
solvent (1) The most abundant component of a solution. (2) The component of a solution in which the other components are considered to be dissolved.
solvent extraction A process for separating a mixture of substances that makes use of their differing solubilities in various solvents.
s-orbital See *atomic orbital*.
space-filling model A depiction of a molecule in which atoms are represented by spheres that indicate the space occupied by each atom.
sp^3d^n hybrid orbital A hybrid orbital formed from one s-orbital, three p-orbitals, and n d-orbitals.
species An atom, ion, or molecule.
specific enthalpy (of a fuel) The enthalpy of combustion per gram (without the negative sign).
specific heat capacity The heat capacity of a sample divided by its mass.
spectator ion An ion that is present but remains unchanged during a reaction. *Examples:* Na^+ and $NO_3{}^-$ in $NaCl(aq) + AgNO_3(aq) \longrightarrow NaNO_3(aq) + AgCl(s)$.
spectral line Radiation of a single wavelength emitted or absorbed by an atom or molecule.
spectrochemical series Ligands ordered according to the strength of the ligand field splitting that they produce.
spectrometer An instrument for recording the spectrum of a sample.
spectrophotometer An instrument for measuring and recording electronically the intensity of radiation passing through a sample as the wavelength of the radiation is changed and hence recording the spectrum of the sample.
spectroscopy The analysis of the electromagnetic radiation emitted, absorbed, or scattered by substances.
spectrum The frequencies or wavelengths of the electromagnetic radiation emitted, absorbed, or scattered by substances.

speed The magnitude of the velocity; the rate of change of position.
sphalerite structure See *zinc-blende structure*.
spherically symmetrical Independent of orientation about a central point.
spherical polar coordinates The coordinates of a point expressed in terms of the *radius r*, the *colatitude* θ, and the *azimuth* ϕ.
sp^n hybrid orbital A hybrid orbital constructed from an s-orbital and *n* p-orbitals. There are two *sp hybrid orbitals*, three *sp^2 hybrid orbitals,* and four *sp^3 hybrid orbitals*.
spin The intrinsic angular momentum of an electron; the spin cannot be eliminated and can occur in only two senses, denoted $\uparrow$ and $\downarrow$ or α and β.
spin magnetic quantum number (m_s) The quantum number that distinguishes the two spin states of an electron: $m_s = +\frac{1}{2}$ ($\uparrow$) and $m_s = -\frac{1}{2}$ ($\downarrow$).
spontaneous change A natural change, one that has a tendency to occur without needing to be driven by an external influence. *Examples:* a gas expanding into a vacuum; a hot object cooling; methane burning.
spontaneous neutron emission The decay of *neutron-rich nuclei* by the emission of neutrons without an external stimulus to do so.
spontaneous nuclear fission See *fission*.
square planar complex A complex in which four ligands lie at the corners of a square with the metal atom at the center.
stability constant See *formation constant*.
stable See *thermodynamically stable compound*.
standard ambient temperature and pressure (SATP) 25°C (298.15 K) and 1 bar.
standard cell potential ($E_{cell}°$) The *cell potential* when the concentration of each solute taking part in the cell reaction is 1 mol·L^{-1} (strictly, unit activity) and all the gases are at 1 bar. The standard cell potential of a galvanic cell is the difference between its two standard potentials: $E_{cell}° = E°(\text{cathode}) - E°(\text{anode})$.
standard emf See *standard cell potential*.
standard enthalpy of combustion ($\Delta H_c°$) The change of enthalpy per mole of substance when it burns (reacts with oxygen) completely under standard conditions.
standard enthalpy of formation ($\Delta H_f°$) The standard reaction enthalpy per mole of compound for the compound's synthesis from its elements in their most stable form at 1 bar and the specified temperature.
standard entropy of fusion ($\Delta S_{fus}°$) The standard entropy change per mole accompanying fusion (the conversion of a substance from the solid state into the liquid state).
standard entropy of vaporization ($\Delta S_{vap}°$) The standard entropy change per mole accompanying vaporization (the conversion of a substance from the liquid state into the vapor state).
standard Gibbs free energy of formation ($\Delta G_f°$) The standard reaction Gibbs free energy per mole for the formation of a compound from its elements in their most stable form.
standard Gibbs free energy of fusion ($\Delta G_{fus}°$) The standard Gibbs free energy change per mole accompanying fusion (the conversion of a substance from the solid state into the liquid state).
standard Gibbs free energy of reaction ($\Delta G°$) The Gibbs free energy of reaction under standard conditions.
standard Gibbs free energy of vaporization ($\Delta G_{vap}°$) The standard Gibbs free energy change per mole accompanying vaporization (the conversion of a substance from the liquid state into the vapor state).
standard hydrogen electrode (SHE) A hydrogen electrode that is in its standard state (hydrogen ions at concentration 1 mol·L^{-1} (strictly, unit activity) and hydrogen pressure 1 bar) and is defined as having $E° = 0$ at all temperatures.
standard molar entropy ($S_m°$) The entropy per mole of a pure substance at 1 bar.
standard potential ($E°$) (1) The contribution of an electrode to the standard emf of a cell. (2) The standard emf of a cell when the left-hand electrode is a standard hydrogen electrode and the right-hand electrode is the electrode of interest.
standard pressure ($P°$) A pressure of 1 bar exactly.
standard reaction enthalpy ($\Delta H°$) The reaction enthalpy under standard conditions.
standard reaction entropy ($\Delta S°$) The reaction entropy under standard conditions.
standard state The pure form of a substance at 1 bar; for a solute, the concentration 1 mol·L^{-1}.
standard temperature and pressure (STP) 0°C (273.15 K) and 1 atm (101.325 kPa).
standing wave A wave stable over time; a wave with peaks and troughs that do not migrate with time.
state function A property of a substance that is independent of how the sample was prepared. *Examples:* pressure; enthalpy; entropy; color.
state of matter The physical condition of a sample. The most common states of a pure substance are solid, liquid, or gas (vapor).
state property See *state function*.
state symbol A symbol (abbreviation) denoting the state of a species. *Examples:* s (solid); l (liquid); g (gas); aq (aqueous solution).
statistical entropy The entropy calculated from statistical thermodynamics; $S = k \ln W$.
statistical thermodynamics The interpretation of the laws of thermodynamics in terms of the behavior of large numbers of atoms and molecules.
steady-state approximation The assumption that the net rate of formation of reaction intermediates is 0.
Stefan–Boltzmann law The total intensity of radiation emitted by a heated black body is proportional to the fourth power of the absolute temperature.
stereoisomers Isomers in which atoms have the same partners arranged differently in space.
stereoregular polymer A polymer in which each unit or pair of repeating units has the same relative orientation.
steric factor (P) An empirical factor that takes into account the steric requirement of a reaction.
steric requirement A constraint on an elementary reaction in which the successful collision of two molecules depends on their relative orientation.
Stern–Gerlach experiment The demonstration of the quantization of electron spin by passing a beam of atoms through a magnetic field.
stick structure See *line structure*.

stock solution A solution stored in concentrated form.
stoichiometric coefficients The numbers multiplying chemical formulas in a chemical equation. *Examples:* 1, 1, and 2 in $H_2 + Br_2 \longrightarrow 2\ HBr$.
stoichiometric point The stage in a titration when exactly the right volume of solution needed to complete the reaction has been added.
stoichiometric proportions Reactants in the same proportions as their coefficients in the chemical equation. *Example:* equal amounts of H_2 and Br_2 in the formation of HBr.
stoichiometric relation An expression that equates the relative amounts of reactants and products that participate in a reaction. *Example:* 1 mol $H_2 \simeq$ 2 mol HBr for $H_2 + Br_2 \longrightarrow 2\ HBr$.
stoichiometry See *reaction stoichiometry.*
stopped-flow technique A procedure for observing fast reactions, involving the spectrometric analysis of a reaction mixture immediately after the rapid injection of reactants into a mixing chamber.
STP See *standard temperature and pressure.*
strong acids and bases Acids and bases that are fully deprotonated or protonated, respectively, in solution. *Examples:* HCl, $HClO_4$ (strong acids); NaOH, $Ca(OH)_2$ (strong bases).
strong electrolyte See *electrolyte.*
strong-field ligand A ligand that produces a large *ligand field splitting* and lies above H_2O in the spectrochemical series.
strong force A short-range but very strong force that acts between nucleons and binds them together to form a nucleus.
structural formula A chemical formula that shows how atoms in a compound are attached to one another. See also *condensed structural formula.*
structural isomers Isomers in which the atoms have different partners.
subatomic particle A particle smaller than an atom. *Examples:* electron; proton; neutron.
subcritical Having a mass less than the *critical mass.*
sublimation The direct conversion of a solid into a vapor without first forming a liquid.
sublimation vapor pressure The vapor pressure of a solid.
subshell All the atomic orbitals of a given shell of an atom that have the same value of the quantum number *l*. *Example:* the five 3d-orbitals of an atom.
substance A single, pure type of matter; either a compound or an element.
substituent An atom or group that has replaced a hydrogen atom in an organic molecule.
substitutional alloy See *alloy.*
substitution reaction (1) A reaction in which an atom (or a group of atoms) replaces an atom in the original molecule. (2) In complexes, a reaction in which one Lewis base expels another and takes its place. *Examples:* (1) $C_6H_5OH + Br_2 \longrightarrow BrC_6H_4OH + HBr$; (2) $[Fe(OH_2)_6]^{3+}(aq) + 6\ CN^-(aq) \longrightarrow [Fe(CN)_6]^{3-}(aq) + 6\ H_2O(l)$.
substrate The chemical species on which an enzyme acts.
superconductor An *electronic conductor* that conducts electricity with zero resistance. See also *high-temperature superconductor.*
supercooled Refers to a liquid cooled to below its freezing point but not yet frozen.
supercritical Having a mass greater than the *critical mass.*
supercritical fluid A fluid phase of a substance above its *critical temperature* and *critical pressure.*
superfluidity The ability to flow without viscosity.
superimpose The combination of atomic orbitals to form a molecular orbital.
surface-active agent See *surfactant.*
surface tension (γ) The tendency of molecules at the surface of a liquid to be pulled inward, resulting in a smooth surface.
surfactant A substance that accumulates at the surface of a solution and affects the surface tension of the solvent; a component of detergents. *Example:* the stearate ion of soaps.
surroundings The region outside a system, where observations are made.
suspension A mist of small particles in a fluid medium.
sustainable development The economical utilization and renewal of resources coupled with hazardous waste reduction and concern for the environment.
symbolic level The discussion of chemical phenomena in terms of chemical symbols and mathematical equations.
synthesis A reaction in which a substance is formed from simpler starting materials. *Example:* $N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$.
synthesis gas A mixture of carbon monoxide and hydrogen produced by the catalyzed reaction of a hydrocarbon and water.
system The object of study, usually a reaction vessel and its contents. An *open system* can exchange both matter and energy with the surroundings. A *closed system* has a fixed amount of matter but can exchange energy with the surroundings. An *isolated system* has no contact with its surroundings.
systematic error An error that persists in a series of measurements and does not average out. See also *accuracy.*
systematic name The name of a compound that reveals which elements are present (and, in its most complete form, how the atoms are arranged). *Example:* methylbenzene is the systematic name for toluene.
Système International d'Unités See *SI.*

temperature (T) (1) How hot or cold a sample is. (2) The intensive property that determines the direction in which heat will flow between two objects in contact.
temperature–composition diagram A *phase diagram* showing how the normal boiling point of a liquid mixture varies with composition.
template synthesis A process in which nanostructures are formed by laying down atoms on a pre-existing substrate.
termination A step in a *chain reaction* in which chain carriers combine to form products. *Example:* $Br\cdot + Br\cdot \longrightarrow Br_2$.
termolecular reaction An *elementary reaction* in which three species collide simultaneously.
tertiary alcohol See *alcohol.*
tertiary structure The shape into which the α-helical and β-sheet sections of a polypeptide are twisted as a result of interactions between peptide groups lying in different parts of the primary structure.

tetrahedral complex A complex in which four ligands lie at the corners of a regular tetrahedron with a metal atom at the center. *Example:* $[Cu(NH_3)_4]^{2+}$.

tetrahedral hole A cavity in a (usually close-packed) crystal structure formed by one sphere lying in the dip formed by three others.

theoretical chemistry The study of molecular structure and properties in terms of mathematical models.

theoretical yield The maximum quantity of product that can be obtained, according to the reaction stoichiometry, from a given quantity of a specified reactant.

theory A collection of ideas and concepts used to account for a scientific law.

thermal decomposition See *decomposition.*

thermal disorder The disorder arising from the thermal motion of molecules.

thermal energy The sum of the potential and kinetic energies due to thermal motion.

thermal equilibrium The state in which a system is at the same temperature as its surroundings.

thermal motion The random, chaotic motion of atoms.

thermal pollution The damage caused to the environment by the waste heat of an industrial process.

thermite reaction (thermite process) The reduction of a metal oxide by aluminum. *Example:* $2\,Al(s) + Fe_2O_3(s) \longrightarrow Al_2O_3(s) + 2\,Fe(l)$.

thermochemical equation An expression consisting of the balanced chemical equation and the corresponding reaction enthalpy.

thermochemistry The study of the heat released or absorbed by chemical reactions; a branch of thermodynamics.

thermodynamically stable compound (1) A compound with no thermodynamic tendency to decompose into its elements. (2) A compound with a negative Gibbs free energy of formation.

thermodynamically unstable compound (1) A compound with a thermodynamic tendency to decompose into its elements. (2) A compound with a positive Gibbs free energy of formation.

thermodynamics The study of the transformations of energy from one form to another. See also *first law of thermodynamics; second law of thermodynamics, third law of thermodynamics.*

thermonuclear explosion An explosion resulting from uncontrolled nuclear fusion.

thermoplastic polymer A polymer that can be softened by heating after it has been molded.

thermosetting polymer A polymer that takes on a permanent shape in a mold and does not soften on heating.

thermotropic liquid crystal A liquid crystal prepared by melting the solid phase.

third law of thermodynamics The entropies of all perfect crystals are the same at the absolute zero of temperature.

third virial coefficient See *virial equation.*

three-center bond A chemical bond in which a hydrogen atom lies between two other atoms (typically boron atoms) and one electron pair binds all three atoms together.

tie line (in a temperature–composition phase diagram) A line joining the point indicating the boiling point of a mixture of given composition with the corresponding composition of the vapor at that temperature.

titrant The solution of known concentration added from a buret in a titration.

titration The analysis of composition by measuring the volume of one solution needed to react with a given volume of another solution. In an *acid–base titration,* an acid is titrated with a base; in a *redox titration,* an oxidizing agent is titrated with a reducing agent.

t-orbital One of the orbitals d_{xy}, d_{yz}, and d_{zx} in an octahedral or tetrahedral complex. In an octahedral complex, these orbitals are designated t_{2g}.

torr (symbol: Torr) A unit of pressure: 760 Torr = 1 atm exactly.

total energy See *energy.*

tracer An isotope that can be tracked from compound to compound in the course of a sequence of reactions.

trajectory The path of a particle on which location and linear momentum are specified at each instant.

transition A change of state. (1) In thermodynamics, a change of physical state. (2) In spectroscopy, a change of quantum state.

transition metal An element that belongs to Groups 3 through 11. *Examples:* vanadium; iron; gold.

transition state See *activated complex.*

transition state theory A theory of reaction rates in which the reactants form an activated complex.

translational kinetic energy See *kinetic energy.*

transmeitnerium elements The elements beyond meitnerium; those with $Z > 109$.

transmutation See *nuclear transmutation.*

transuranium elements The elements beyond uranium; those with $Z > 92$.

triboluminescence Luminescence that results from mechanical shock to a crystal.

triple bond (1) Three electron pairs shared by two neighboring atoms. (2) One σ-bond and two π-bonds between neighboring atoms.

triple point The point where three phase boundaries meet in a phase diagram. Under the conditions represented by the triple point, all three adjoining phases coexist in dynamic equilibrium.

triprotic See *polyprotic acid or base.*

Trouton's rule The empirical observation that the entropy of vaporization at the boiling point (the enthalpy of vaporization divided by the boiling temperature) is approximately $85\ J{\cdot}K^{-1}{\cdot}mol^{-1}$ for many liquids.

tube structure A representation of molecular structure that uses tubes to indicate the lengths and distances of bonds. The ends of each tube are colored to indicate the identities of the elements forming the bond.

ultraviolet catastrophe The classical prediction that any black body at any temperature should emit intense ultraviolet radiation.

ultraviolet radiation Electromagnetic radiation with a higher frequency (shorter wavelength) than that of violet light.

unbranched alkane An alkane with no side chains, in which all the carbon atoms lie in a linear chain.

uncertainty principle See *Heisenberg uncertainty principle.*

unimolecular reaction An elementary reaction in which a single reactant molecule changes into products. *Example:* $O_3 \rightarrow O_2 + O$.

unique average reaction rate The rate of change in the concentration of a reactant or product divided by its stoichiometric coefficient in the balanced equation. All unique average rates are reported as positive quantities. See also *average reaction rate*.

unit See *base units*.

unit cell The smallest unit that, when stacked together repeatedly without any gaps, can reproduce an entire crystal.

universe (in thermodynamics) The system and its surroundings.

unsaturated hydrocarbon A hydrocarbon with at least one carbon–carbon multiple bond. *Examples:* $CH_2{=}CH_2$; C_6H_6.

valence The number of bonds that an atom can form.

valence band In the theory of solids, a band of energy levels fully occupied by electrons.

valence-bond theory The description of bond formation in terms of the pairing of spins in the atomic orbitals of neighboring atoms.

valence electrons The electrons that belong to the valence shell.

valence shell The outermost shell of an atom. *Example:* the $n = 2$ shell of Period 2 atoms.

valence-shell electron-pair repulsion model (VSEPR model) A model for predicting the shapes of molecules, using the fact that electron pairs repel one another.

van der Waals equation An approximate equation of state for a real gas in which two parameters represent the effects of intermolecular forces.

van der Waals interactions Intermolecular interactions that depend on the inverse sixth power of the separation. See *intermolecular forces*.

van der Waals parameters The experimentally determined coefficients that appear in the van der Waals equation and are unique for each real gas. The parameter a is an indication of the strength of attractive intermolecular forces, and the parameter b is an indication of the strength of repulsive intermolecular forces. See also *van der Waals equation*.

van der Waals radius Half the distance between the centers of nonbonded, touching atoms in a solid.

van 't Hoff equation (1) The equation for the osmotic pressure in terms of the molarity, $\Pi = i[J]RT$. (2) An equation that shows how the equilibrium constant varies with temperature.

van 't Hoff *i* factor See *i* factor.

vapor The gaseous phase of a substance (specifically, of a substance that is a liquid or solid at the temperature in question). See also *gas*.

vaporization The formation of a gas or a vapor from a liquid.

vapor-phase synthesis A process in which a substance is vaporized and then condensed or mixed with a reactant and the condensed product forms tiny crystals.

vapor pressure The pressure exerted by the vapor of a liquid (or a solid) when the vapor and the liquid (or solid) are in dynamic equilibrium.

variable covalence The ability of an element to form different numbers of covalent bonds. *Example:* S in SO_2 and SO_3.

variable valence The ability of an element to form ions with different charges. *Example:* In^+ and In^{3+}.

velocity The rate of change of position.

vibrational kinetic energy See *kinetic energy*.

virial equation An equation of state expressed in powers of $1/V_m$: specifically, $PV = nRT(1 + B/V_m + C/V_m{}^2 + \cdots)$, where B is the *second virial coefficient* and C is the *third virial coefficient*.

viscosity The resistance of a fluid (a gas or a liquid) to flow: the higher the viscosity, the slower the flow.

visible light See *visible radiation*.

visible radiation Electromagnetic radiation that can be detected by the human eye, with wavelengths in the range from 700 nm to 400 nm. Visible radiation is also called *visible light* or simply *light*.

volatile Having a high vapor pressure at ordinary temperatures. A substance is typically regarded as volatile if its boiling point is below 100°C.

volatility The readiness with which a substance vaporizes. See also *volatile*.

volt (V) The SI unit of electrical potential. See also Appendix 1B.

voltaic cell See *electrochemical cell*.

volume (V) The amount of space that a sample occupies.

volumetric analysis An analytical method using measurement of volume, as in a *titration*.

volumetric flask A flask calibrated to contain a specified volume.

water autoprotolysis constant (K_w) The equilibrium constant for the autoprotolysis (autoionization) of water, $2\,H_2O(l) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$, $K_w = [H_3O^+][OH^-]$.

water of hydration See *hydration*.

water-splitting reaction The photochemical decomposition of water into hydrogen and oxygen.

wavefunction (ψ) A solution of the Schrödinger equation; the probability amplitude.

wavelength (λ) The peak-to-peak distance of a wave.

wave–particle duality The combined wavelike and particlelike character of both radiation and matter.

weak acids and bases Acids and bases that are only incompletely deprotonated or protonated, respectively (commonly, in aqueous solution) at normal concentrations. *Examples:* HF, CH_3COOH (weak acids); NH_3, CH_3NH_2 (weak bases).

weak electrolyte See *electrolyte*.

weak-field ligand A ligand that produces a small *ligand field splitting* and that lies below NH_3 in the *spectrochemical series*.

Wien's law The wavelength corresponding to the maximum in the radiation emitted by a heated *black body* is inversely proportional to the absolute temperature.

work (w) The energy expended during the act of moving an object against an opposing force. In *expansion work*, the

system expands against an opposing pressure; *nonexpansion work* is work that does not arise from a change in volume.

work function (Φ) The energy required to remove an electron from a metal.

x-ray Electromagnetic radiation with wavelengths from about 10 pm to about 1000 pm.

x-ray diffraction The analysis of crystal structures by studying the interference pattern in a beam of x-rays.

yield See *percentage yield; theoretical yield*.

zeolite A microporous aluminosilicate.

zero-order reaction A reaction with a rate that is independent of the concentration of the reactant. *Example:* the catalyzed decomposition of ammonia.

zero-point energy The lowest possible energy of a system. *Example:* $E = h^2/8mL^2$ for a particle of mass m in a box of length L.

Ziegler–Natta catalyst A stereospecific catalyst for polymerization reactions, consisting of titanium tetrachloride and triethylaluminum.

zinc-blende structure A crystal structure in which the cations occupy half the tetrahedral holes in a nearly close-packed cubic lattice of anions; also known as *sphalerite structure*.

zone refining A method for purifying a solid by repeatedly passing a molten zone along the length of a sample.

zwitterion A form of an amino acid in which in which the amino group is protonated and the carboxyl group is deprotonated. *Example*: $^+H_3NCH_2CO_2^-$.

ANSWERS

Self-Tests B

Fundamentals

A.1B 250. g × 1.000 lb/453.6 g × 16 oz/1 lb = 8.82 oz

A.2B $9.81\ \text{m·s}^{-2} \times 1\ \text{km}/10^3\ \text{m} \times (3600\ \text{s}/1\ \text{h})^2 = 1.27 \times 10^5\ \text{km·h}^{-2}$

A.3B $V = m/d = (10.0\ \text{g})/(0.17685\ \text{g·L}^{-1}) = 56.5\ \text{L}$

A.4B $E_k = mv^2/2 = {}^1/_2 \times (1.5\ \text{kg}) \times (3.0\ \text{m·s}^{-1})^2 = 6.8\ \text{J}$

A.5B $E_k = mgh = (0.350\ \text{kg}) \times (9.81\ \text{m·s}^{-2}) \times (443\ \text{m}) \times (10^{-3}\ \text{kJ/J}) = 1.52\ \text{kJ}$

B.1B number of Au atoms = m(sample)/m(one atom) = (0.0123 kg)/(3.27×10^{-25} kg) = 3.76×10^{22} Au atoms

B.2B (a) 8, 8, 8; (b) 92, 144, 92

C.1B (a) Potassium is a Group 1 metal. Cation, +1, so K^+. (b) Sulfur is a nonmetal in Group 16/VI. Anion, 16 − 18 = −2, so S^{2-}.

C.2B (a) Li_3N; (b) $SrBr_2$

D.1B (a) dihydrogen arsenate; (b) ClO_3^-

D.2B (a) gold(III) chloride; (b) calcium sulfide; (c) manganese(III) oxide

D.3B (a) phosphorus trichloride; (b) sulfur trioxide; (c) hydrobromic acid

D.4B (a) $Cs_2S·4H_2O$; (b) Mn_2O_7; (c) HCN; (d) S_2Cl_2

D.5B (a) pentane; (b) carboxylic acid

E.1B atoms of H = (3.14 mol H_2O) × (2 mol H)/(1 mol H_2O) × (6.022×10^{23} atoms/mol) = 3.78×10^{24} H atoms

E.2B (a) $n = m/M = (5.4 \times 10^3\ \text{g})/(26.98\ \text{g·mol}^{-1}) = 2.0 \times 10^2$ mol; (b) $N = N_A \times n = (6.022 \times 10^{23}$ Al atoms/mol) × (2.0×10^2 mol) = 1.2×10^{26} Al atoms

E.3B copper-63: $(62.94\ \text{g·mol}^{-1}) \times 0.6917 = 43.536\ \text{g·mol}^{-1}$; copper-65: $(64.93\ \text{g·mol}^{-1}) \times 0.3083 = 20.018\ \text{g·mol}^{-1}$; $43.536\ \text{g·mol}^{-1} + 20.018\ \text{g·mol}^{-1} = 63.55\ \text{g·mol}^{-1}$

E.4B (a) phenol: 6 C, 6 H, 1 O; $6(12.01\ \text{g·mol}^{-1}) + 6(1.008\ \text{g·mol}^{-1}) + (16.00\ \text{g·mol}^{-1}) = 94.11\ \text{g·mol}^{-1}$;(b) $Na_2CO_3·10H_2O$: 2 Na, 1 C, 13 O, 20 H; $2(22.99\ \text{g·mol}^{-1}) + (12.01\ \text{g·mol}^{-1}) + 13(16.00\ \text{g·mol}^{-1}) + 20(1.008\ \text{g·mol}^{-1}) = 286.15\ \text{g·mol}^{-1}$

E.5B $Ca(OH)_2$: 1 Ca, 2 O, 2 H; $(40.08\ \text{g·mol}^{-1}) + 2(16.00\ \text{g·mol}^{-1}) + 2(1.008\ \text{g·mol}^{-1}) = 74.10\ \text{g·mol}^{-1}$; $(1.00 \times 10^3$ g lime$)/(74.10\ \text{g·mol}^{-1})$ = 13.5 mol formula units of lime

E.6B CH_3COOH: 2 C, 4 H, 2 O; $2(12.01\ \text{g·mol}^{-1}) + 4(1.008\ \text{g·mol}^{-1}) + 2(16.00\ \text{g·mol}^{-1}) = 60.05\ \text{g·mol}^{-1}$; $(60.05\ \text{g·mol}^{-1})(1.5\ \text{mol}) = 90.$ g

F.1B % C = (6.61 g/7.50 g) × 100% = 88.1%; % H = (0.89 g/7.50 g) × 100% = 11.9%

F.2B $AgNO_3$: $(107.87\ \text{g·mol}^{-1}) + (14.01\ \text{g·mol}^{-1}) + 3\ (16.00\ \text{g·mol}^{-1}) = 169.88\ \text{g·mol}^{-1}$; % Ag = $(107.87\ \text{g·mol}^{-1})/(169.88\ \text{g·mol}^{-1}) \times 100\%$ = 63.498%

F.3B carbon: 0.778 × (100 g eucalyptol) = 77.8 g C; (77.8 g C)/$(12.01\ \text{g·mol}^{-1})$ = 6.48 mol C; hydrogen: (11.8 g H)/$(1.0079\ \text{g·mol}^{-1})$ = 11.7 mol H; oxygen: (10.4 g O)/$(16.00\ \text{g·mol}^{-1})$ = 0.650 mol O; 6.48 C:11.7 H:0.650 O

F.4B n(O) = (18.59 g)/$(16.00\ \text{g·mol}^{-1})$ = 1.162 mol O; n(S) = (37.25 g)/$(32.07\ \text{g·mol}^{-1})$ = 1.162 mol; n(F) = (44.16 g)/$(19.00\ \text{g·mol}^{-1})$ = 2.324 mol. 1:1:2 ratio, formula is SOF_2.

F.5B $M(CHO_2) = 45.012\ \text{g·mol}^{-1}$. $(90.0\ \text{g·mol}^{-1})/(45.012\ \text{g·mol}^{-1})$ = 2.00; 2 × (CHO_2) = $C_2H_2O_4$

G.1B $M(Na_2SO_4) = 142.05\ \text{g·mol}^{-1}$. (15.5 g)/$(142.05\ \text{g·mol}^{-1})$ = 0.109 mol; (0.109 mol)/(0.350 L) = 0.312 M Na_2SO_4(aq)

G.2B $(0.125\ \text{mol·L}^{-1})$ × (0.05000 L) = 0.00625 mol oxalic acid. M(oxalic acid) = $90.036\ \text{g·mol}^{-1}$. (0.00625 mol) × $(90.036\ \text{g·mol}^{-1})$ = 0.563 g oxalic acid

G.3B (2.55×10^{-3} mol HCl)/(0.358 mol HCl/L) = 7.12×10^{-3} L = 7.12 mL

G.4B $V_{init} = (c_{final} \times V_{final})/c_{init} = (1.59 \times 10^{-5}\ \text{mol·L}^{-1}) \times (0.02500\ \text{L})/(0.152\ \text{mol·L}^{-1}) = 2.62 \times 10^{-3}$ mL

H.1B $Mg_3N_2(s) + 4\ H_2SO_4(aq) \longrightarrow 3\ MgSO_4(aq) + (NH_4)_2SO_4(aq)$

I.1B (a) molecular compound and not an acid, so a nonelectrolyte, does not conduct electricity; (b) ionic compound, so a strong electrolyte, conducts electricity

I.2B $3\ Hg_2^{2+}(aq) + 2\ PO_4^{3-}(aq) \longrightarrow (Hg_2)_3(PO_4)_2(s)$

I.3B $SrCl_2$ and Na_2SO_4; $Sr^{2+}(aq) + SO_4^{2-}(aq) \longrightarrow SrSO_4(s)$

J.1B (a) is neither an acid nor a base; (b) and (c) are acids; (d) *supplies* the base OH^-

J.2B $3\ Ca(OH)_2(aq) + 2\ H_3PO_4(aq) \longrightarrow Ca_3(PO_4)_2(s) + 6\ H_2O$

K.1B $Cu^+(aq)$ is oxidized, $I_2(s)$ is reduced.

K.2B (a) $x + 3(-2) = -2$; $x = +4$ for S; (b) $x + 2(-2) = -1$; $x = +3$ for N; (c) $x + 1 + 3(-2) = 0$; $x = +5$ for Cl

K.3B H_2SO_4 is the oxidizing agent (S is reduced from +6 to +4); NaI is the reducing agent (I is oxidized from −1 to +5).

K.4B $2\ Ce^{4+}(aq) + 2\ I^-(aq) \longrightarrow 2\ Ce^{3+}(aq) + I_2(s)$

L.1B (2 mol Fe)/(1 mol Fe_2O_3) × 25 mol Fe_2O_3 = 50. mol Fe

L.2B 2 mol CO_2/1 mol $CaSiO_3$; mol CO_2 = (3.00×10^2 g)/$(44.01\ \text{g·mol}^{-1})$ = 6.82 mol; (1 mol $CaSiO_3$/2 mol CO_2) × (6.82 mol CO_2) = 3.41 mol $CaSiO_3$; (3.41 mol $CaSiO_3$) × $(116.17\ \text{g·mol}^{-1}$ $CaSiO_3$) = 396 g $CaSiO_3$

L.3B $2\ KOH + H_2SO_4 \longrightarrow K_2SO_4 + 2\ H_2O$; 2 mol KOH $\simeq$ 1 mol H_2SO_4; $(0.255\ \text{mol KOH·L}^{-1})$ × (0.025 L) = 6.375×10^{-3} mol KOH. (6.375×10^{-3} mol KOH) × (1 mol H_2SO_4)/(2 mol KOH) = 3.19×10^{-3} mol H_2SO_4; (3.19×10^{-3} mol H_2SO_4)/ (0.01645 L) = 0.194 M H_2SO_4

L.4B (0.100 × 0.02815) mol $KMnO_4$ × (5 mol As_4O_6)/(8 mol $KMnO_4$) × $395.28\ \text{g·mol}^{-1}$ = 6.96×10^{-2} g As_4O_6

M.1B $2\ Fe_2O_3(s) \longrightarrow 4\ Fe(s) + 3\ O_2(g)$; (15 kg Fe_2O_3)/$159.69\ \text{g·mol}^{-1}$) × (2 mol Fe)/(1 mol Fe_2O_3) × $(55.85\ \text{g·mol}^{-1})$ = 10.5 kg Fe; 8.8 kg/10.5 kg × 100% = 84% yield

M.2B $2\ NH_3 + CO_2 \longrightarrow OC(NH_2)_2 + H_2O$; $n(NH_3)$ = (14.5×10^3 g)/$(17.034\ \text{g·mol}^{-1})$ = 851 mol NH_3; $n(CO_2)$ = (22.1×10^3 g)/$(44.01\ \text{g·mol}^{-1})$ = 502 mol CO_2; 2 mol NH_3 $\simeq$ 1 mol CO_2; (a) NH_3 is the limiting reactant. (851 mol NH_3/2) < (502 mol CO_2). (b) 2 mol NH_3/1 mol urea. 426 mol, or 25.6 kg of urea can be produced. (c) (502 − 426) mol = 76 mol CO_2 excess = 3.3 kg CO_2

M.3B $3\ NO_2(g) + H_2O(l) \longrightarrow 2\ HNO_3(l) + NO(g)$. There is 0.61 mol NO_2 and 1.0 mol H_2O. 1 mol H_2O $\simeq$ 3 mol NO_2; therefore, there is not enough NO_2, so NO_2 is the limiting reactant. 22 g, or 0.35 mol HNO_3, were produced. Theoretical yield is (0.61 mol NO_2) × (2 mol HNO_3)/(3 mol NO_2) = 0.407 mol HNO_3. Percentage yield = (0.35 mol)/(0.407 mol) × 100% = 86%.

M.4B The sample contains 0.0118 mol C (0.142 g C) and 0.0105 mol H (0.0106 g H). Mass of O = 0.236 − (0.142 + 0.0105)g = 0.0834 g O (0.00521 mol O). The C:H:O mole ratios are 0.0118:0.0105:0.00521, or 2.26:2.02:1. Multiplying these numbers by 4 gives 9:8:4 and the empirical formula $C_9H_8O_4$.

Chapter 1

1.1B $\lambda = c/\nu = (2.998 \times 10^8\ \text{m·s}^{-1})/(98.4 \times 10^6\ \text{Hz}) = 3.05$ m

1.2B $\nu = R(1/2^2 - 1/5^2) = 21R/100$; $\lambda = c/\nu = 100c/21R = (100 \times 2.998 \times 10^8\ \text{m·s}^{-1})/(21 \times 3.29 \times 10^{15}\ \text{s}^{-1}) = 434$ nm; violet line

1.3B $T = \text{constant}/\lambda_{max} = (2.9 \times 10^{-3}\ \text{m·K})/(700. \times 10^{-9}\ \text{m}) = 4.1 \times 10^3$ K

1.4B $E = h\nu = (6.626 \times 10^{-34}\ \text{J·s}) \times (4.8 \times 10^{14}\ \text{Hz}) = 3.2 \times 10^{-19}$ J

1.5B (a) $E_k = 1/2 \times (9.109 \times 10^{-31}\ \text{kg}) \times (7.85 \times 10^5\ \text{m·s}^{-1})^2 = 2.81 \times 10^{-19}$ J; (b) 3.63 eV $\times (1.602 \times 10^{-19}\ \text{J·eV}^{-1}) = 5.82 \times 10^{-19}$ J, $\lambda = [(3.00 \times 10^8\ \text{m·s}^{-1}) \times (6.626 \times 10^{-34}\ \text{J·s})]/(5.82 \times 10^{-19}\ \text{J}) = 342$ nm
1.6B $\lambda = h/mv = (6.626 \times 10^{-34}\ \text{J·s})/(0.0050\ \text{kg} \times 2 \times 331\ \text{m·s}^{-1}) = 2.0 \times 10^{-34}$ m
1.7B $\Delta v = \hbar/2m\Delta x = (1.05457 \times 10^{-34}\ \text{J})/(2 \times 2.0\ \text{t} \times 10^3\ \text{kg·t}^{-1} \times 1\ \text{m}) = 3 \times 10^{-38}\ \text{m·s}^{-1}$
1.8B $E_3 - E_2 = 5h^2/8m_eL^2 = h\nu$; $\nu = 5h/8m_eL^2$; $\lambda = c/\nu = 8m_ecL^2/5h = [8 \times (9.10939 \times 10^{-31}\ \text{kg}) \times (2.998 \times 10^8\ \text{m·s}^{-1}) \times (1.50 \times 10^{-10}\ \text{m})^2]/(5 \times 6.626 \times 10^{-34}\ \text{J·s}) = 14.8 \times 10^{-9}$ m, or 14.8 nm
1.9B ratio $= (e^{-6a_0/a_0}/\pi a_0^3)/(1/\pi a_0^3) = e^{-6} = 0.0025$
1.10B 3p
1.11B $1s^22s^22p^63s^23p^1$ or $[Ne]3s^23p^1$
1.12B $[Ar]3d^{10}4s^24p^3$
1.13B (a) $r(Ca^{2+}) < r(K^+)$; (b) $r(Cl^-) < r(S^{2-})$
1.14B In the third ionization of Be, the electron is removed from the noble-gas core, but in the third ionization of B, the electron is removed from the valence shell. Core electrons are closer to the nucleus, so greater amounts of energy are required to remove them.
1.15B In fluorine (Group 17), an additional electron fills the single vacancy in the valence shell; the shell now has the noble-gas configuration of neon and is complete. In neon, an additional electron would have to enter a new shell, where it would be farther from the attraction of the nucleus.

Chapter 2

2.1B (a) $[Ar]3d^5$; (b) $[Xe]4f^{14}5d^{10}$
2.2B I^-, $[Kr]4d^{10}5s^25p^6$
2.3B KCl, because Cl^- has a smaller radius than Br^-
2.4B ; H has no lone pairs, Br has 3 lone pairs.
2.5B 2.6B 2.7B 2.8B 2.9B 2.10B ; 10 electrons

separation = 2.25 m − 2.22 m = 0.03 m, or 30. cm

6.10B $SiO_2(s) + OH^-(aq) \longrightarrow HSiO_3^-(aq)$

6.11B $10.\text{ kg }SiO_2\times\dfrac{10^{3}\text{ g }SiO_2}{1\text{ kg }SiO_2}\times\dfrac{1\text{ mol }SiO_2}{60.09\text{ g }SiO_2}\times\dfrac{30\text{ mol e}^-}{1\text{ mol }SiO_2}\times\dfrac{6.022\times10^{23}\text{ e}^-}{1\text{ mol e}^-}\times\dfrac{9.10939\times10^{-31}\text{ kg}}{1\text{ e}^-}\times\dfrac{10^{3}\text{ g e}^-}{1\text{ kg e}^-} = 0.27\text{ g}$

6.12B

$$R = \frac{l}{A\times\kappa} = \frac{0.10\text{ mm}\times\dfrac{1\text{ m}}{10^{3}\text{ mm}}}{\left(1.0\text{ cm}^2\times\dfrac{1\text{ m}^2}{(100\text{ cm})^2}\right)\left(0.2\text{ mS}\cdot\text{m}^{-1}\times\dfrac{1\text{ S}}{10^{3}\text{ mS}}\right)} = 5\times10^{3}\text{ S}^{-1}\times\frac{1\,\Omega}{1\text{ S}^{-1}} = 5\times10^{3}\,\Omega$$

6.13B $1.0\text{ cm}\times\dfrac{10^{12}\text{ pm}}{10^{2}\text{ cm}}\times\dfrac{1\text{ Ca atom}}{(2\times197\text{ pm})}\times\dfrac{2\text{ valence e}^-}{1\text{ Ca atom}}\times\dfrac{1\text{ orbital}}{2\text{ valence e}^-} = 2.5\times10^{7}$

6.14B p-type

6.15B In chemiluminescence, light is emitted as the result of molecules being excited during a chemical reaction. In phosphorescence, light is emitted when molecules remain excited after the stimulus has ceased.

6.16B

(a) $6.0\text{ mL}\times\dfrac{1\text{ L}}{10^{3}\text{ mL}}\times\dfrac{0.0012\text{ mol }Pb^{2+}}{1\text{ L}}\times\dfrac{1\text{ mol PbSe}}{1\text{ mol }Pb^{2+}}\times\dfrac{6.022\times10^{23}\text{ f.u.}}{1\text{ mol PbSe}}\times\dfrac{1\text{ q.d.}}{165\text{ f.u.}}\times\dfrac{1\text{ mol q.d.}}{6.022\times10^{23}\text{ q.d.}}\times\dfrac{1}{2\times6.0\text{ mL}}\times\dfrac{10^{3}\text{ mL}}{1\text{ L}} = 3.6\times10^{-6}\text{ mol}\cdot\text{L}^{-1}$

(b) $165\times(207.2+78.96)\text{ g}\cdot\text{mol}^{-1}\times(1\text{ kg})/(1000\text{ g}) = 47.2\text{ kg}\cdot\text{mol}^{-1}$

(c) $d = 2r = 2\times\left(\dfrac{3h\lambda}{8m_ec}\right)^{1/2} = 2\times\left(\dfrac{3\times(6.626\times10^{-34}\text{ J}\cdot\text{s})\times(601\times10^{-9}\text{ m})}{8\times(9.109\times10^{-31}\text{ kg})\times(2.998\times10^{8}\text{ m}\cdot\text{s}^{-1})}\right)^{1/2} =$ 1.48 mm

Chapter 7

7.1B $w = -P\Delta V = -(9.60\text{ atm})\times(2.2\text{ L}-0.22\text{ L})\times(101.325\text{ J}\cdot\text{L}^{-1}\cdot\text{atm}^{-1}) = -1926\text{ J} = -1.9\text{ kJ}$

7.2B $w = -P\Delta V = -(1.00\text{ atm})\times(4.00\text{ L}-2.00\text{ L})\times101.325\text{ J}\cdot\text{L}^{-1}\cdot\text{atm}^{-1} = -202\text{ J}$; $w = -nRT\ln(V_{final}/V_{initial}) = -(1.00\text{ mol})\times(8.3145\text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1})\times(303\text{ K})\times\ln(4.00\text{ L}/2.00\text{ L}) = -1.75\text{ kJ}$; isothermal reversible expansion does more work

7.3B $q = nC_m\Delta T = (3.00\text{ mol})\times(111\text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1})\times[15°\text{C}\times(1\text{ K}/1°\text{C})] = 5.0\text{ kJ}$

7.4B $C_{cal} = \dfrac{q_{cal}}{\Delta T} = \dfrac{4.16\text{ kJ}}{3.24°\text{C}} = 1.28\text{ kJ}\cdot(°\text{C})^{-1}$

7.5B $w = \Delta U - q = -150\text{ J} - (+300\text{ J}) = -450\text{ J}$; $w < 0$ (the system did work)

7.6B $q = +1.00\text{ kJ}$; $w = -(2.00\text{ atm})\times(3.00\text{ L}-1.00\text{ L})-(101.325\text{ J}\cdot\text{L}^{-1}\cdot\text{atm}^{-1}) = -405\text{ J}$; $\Delta U = q + w = 1.00\text{ kJ} + (-0.405\text{ kJ}) = +0.60\text{ kJ}$

7.7B (a) $\Delta H = +30\text{ kJ}$; (b) $\Delta U = q + w = 30\text{ kJ} + 40\text{ kJ} = +70\text{ kJ}$

7.8B

(a) $\Delta T = \dfrac{q}{nC_V} = \dfrac{1.20\text{ kJ}\times\dfrac{1000\text{ J}}{1\text{ kJ}}}{1.00\text{ mol}\times\left(\dfrac{5}{2}\times8.3145\text{ L}\cdot\text{atm}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}\right)} =$

57.7 K, $T_f = 298\text{ K} + 57.7\text{ K} = 356\text{ K}$; $\Delta U = q + w = 1.20\text{ kJ} + 0 = 1.20\text{ kJ}$

(b) (step 1) constant volume, find final temperature:

$$\Delta T = \frac{q}{nC_P} = \frac{1.20\text{ kJ}\times\dfrac{1000\text{ J}}{1\text{ kJ}}}{1.00\text{ mol}\times\left(\dfrac{7}{2}\times8.3145\text{ L}\cdot\text{atm}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}\right)} =$$

41.2 K;

$T_f = 298\ \text{K} + 41.2\ \text{K} = 339\ \text{K}$; $\Delta U = q + w = q + 0$, so $\Delta U = q = nC_V\Delta T = (1\ \text{mol}) \times (5/2) \times (8.3145\ \text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}) \times (41.2\ \text{K}) = 856\ \text{J}$; (step 2) isothermal, $\Delta T = 0$, so $\Delta U = 0$; Therefore, after both steps, $\Delta U = +856\ \text{J}$, $T_f = 339\ \text{K}$

7.9B $\dfrac{22\ \text{kJ}}{23\ \text{g}} \times \dfrac{46.07\ \text{g}}{1\ \text{mol}} = 44\ \text{kJ}\cdot\text{mol}^{-1}$

7.10B $\Delta H_{sub} = \Delta H_{vap} + \Delta H_{fus} = (38 + 3)\ \text{kJ}\cdot\text{mol}^{-1} = 41\ \text{kJ}\cdot\text{mol}^{-1}$

8.6B
$$\Delta S_{vap}^\circ = \frac{\Delta H_{vap}}{T_b} = \frac{40.7\ \text{kJ}\cdot\text{mol}^{-1}}{373.2\ \text{K}} \times \frac{10^3\ \text{J}}{1\ \text{kJ}} = 109\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$$

8.7B $\Delta H_{vap}^\circ = (85\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1})(273.2\ \text{K} + 24.5\ \text{K}) \times (1\ \text{kJ}/10^3\ \text{J}) = 26.2\ \text{kJ}\cdot\text{mol}^{-1}$

8.8B $\Delta S_{fus}^\circ = \Delta H_{fus}^\circ/T_f = (10.59 \times 10^3\ \text{J}\cdot\text{mol}^{-1})/(278.6\ \text{K}) = 38.01\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$

8.9B $\Delta S = k\ \ln W = (1.38066 \times 10^{-23}\ \text{J}\cdot\text{K}^{-1})(1.0\ \text{mol})(6.022 \times 10^{23}\ \text{mol}^{-1})\ \ln(6) = +15\ \text{J}\cdot\text{K}^{-1}$

8.10B Nonzero entropy at $T = 0$ indicates disorder. This disorder results when a molecule can orient itself more than one way in the crystal. In ice, each O atom is surrounded by four H atoms, of which there are two types. Two of the H atoms are covalently bonded to the O atom and the other two H atoms, which belong to neighboring water molecules, are interacting with the central O atom through hydrogen bonds. Thus, more than one orientation is possible in the crystal and entropy will not be zero at $T = 0$.

8.11B (a) $\Delta S = S_{gray} - S_{white} = (44.14 - 51.55)\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1} = -7.41\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$; the gray form; (b) $\Delta S = S_{graphite} - S_{diamond} = (5.7 - 2.4)\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1} = +3.3\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$; diamond

8.12B positive, because a gas is produced from a solid

8.13B $\Delta S_r^\circ = (229.60 - 219.56 - 130.68)\ \text{J}\cdot\text{K}^{-1} = -120.64\ \text{J}\cdot\text{K}^{-1}$

8.14B $\Delta S_{surr} = -\Delta H/T = -(2.00\ \text{mol} \times -46.11\ \text{kJ}\cdot\text{mol}^{-1})/298\ \text{K} \times (10^3\ \text{J}/1\ \text{kJ}) = +309\ \text{J}\cdot\text{K}^{-1}$

8.16B $\Delta S = nR \times \ln(V_2/V_1) = (2.00\ \text{mol}) \times (8.3145\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}) \times \ln(0.200/4.00) = -49.8\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$; $\Delta S_{surr} = +49.8\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$; $\Delta S_{tot} = 0$

8.17B $\Delta S_{surr} = -\Delta H_{vap}/T = -(30.8 \times 10^3\ \text{J}\cdot\text{mol}^{-1})/353.2\ \text{K} = -87.2\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$; $\Delta S = +87.2\ \text{J}\cdot\text{K}^{-1}$; $\Delta S_{tot} = \Delta S + \Delta S_{surr} = +87.2\ \text{J}\cdot\text{K}^{-1} + (-87.2\ \text{J}\cdot\text{K}^{-1}) = 0$ at 353.2 K

8.18B Yes. $\Delta G = \Delta H - T\Delta S$. When $\Delta S > 0$, $T\Delta S > 0$. Hence, as temperature increases, $-T\Delta S$ becomes more negative; eventually $\Delta G < 0$ and the process becomes spontaneous.

8.19B (a) $\Delta G_m = \Delta H_m - T\Delta S_m = 59.3\ \text{kJ}\cdot\text{mol}^{-1} - (623\ \text{K}) \times (0.0942\ \text{kJ}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}) = +0.6\ \text{kJ}\cdot\text{mol}^{-1}$; vaporization is nonspontaneous; (b) $\Delta G_m = \Delta H_m - T\Delta S_m = 59.3\ \text{kJ}\cdot\text{mol}^{-1} - (643\ \text{K}) (0.0942\ \text{kJ}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}) = -1.3\ \text{kJ}\cdot\text{mol}^{-1}$; vaporization is spontaneous.

8.20B $3\ H_2\ (g) + 3\ C\ (s, \text{graphite}) \longrightarrow C_3H_6\ (g)$, $\Delta S_r = 237.4\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1} - [3(130.68\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}) + 3(5.740\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1})] = -171.86\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$, $\Delta G_r = \Delta H_r - T\Delta S_r = +53.30\ \text{kJ}\cdot\text{mol}^{-1} - (298\ \text{K})(-171.86\ \text{J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}) \times (1\ \text{kJ}/10^3\ \text{J}) = +104.5\ \text{kJ}\cdot\text{mol}^{-1}$

8.21B From Appendix 2A, $\Delta G_f^\circ(CH_3NH_2, g) = +32.16\ \text{kJ}\cdot\text{mol}^{-1}$ at 298 K. Because $\Delta G_f^\circ > 0$, CH_3NH_2 is less stable than its elements at the stated conditions.

8.22B $\Delta G = [-910 + (6\ \text{mol})(0)] \times [(6\ \text{mol})(-394.36) + (6\ \text{mol})(-237.13)] = +2879\ \text{kJ}$

8.23B $MgCO_3(s) \longrightarrow MgO(s) + CO_2(g)$; $\Delta H^\circ = -601.70 + (-393.51) - (-1095.8) = +100.6\ \text{kJ}$; $\Delta S^\circ = 26.94 + 213.74 - 65.7\ \text{J}\cdot\text{K}^{-1} = +175.0\ \text{J}\cdot\text{K}^{-1}$;

$$T = \frac{\Delta H^\circ}{\Delta S^\circ} = \frac{100.6\ \text{kJ}}{175.0\ \text{J}\cdot\text{K}^{-1}} \times \frac{10^3\ \text{J}}{1\ \text{kJ}} = 574.9\ \text{K}$$

Chapter 9

9.1B $CH_3CH_2CH_3$; molecules of the two substances have the same molar mass and thus the same number of electrons and comparable London forces. However, CH_3CHO is polar and also experiences dipole–dipole forces.

9.2B
$$\ln\left(\frac{P_2}{94.6\ \text{Torr}}\right) = \frac{30.8 \times 10^3\ \text{J}\cdot\text{mol}^{-1}}{8.3145\ \text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}}\left(\frac{1}{298\ \text{K}} - \frac{1}{308\ \text{K}}\right);$$

$P_2 = 142\ \text{Torr}$

9.3B
$$\ln\left(\frac{760\ \text{Torr}}{400\ \text{Torr}}\right) = \frac{35.3 \times 10^3\ \text{J}\cdot\text{mol}^{-1}}{8.3145\ \text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}}\left(\frac{1}{323\ \text{K}} - \frac{1}{T_2}\right);$$

$T_2 = 339\ \text{K}$

9.4B The positive slope of the solid−liquid boundary shows that monoclinic sulfur is more dense than liquid sulfur over the temperature range in which monoclinic sulfur is stable; the solid is more stable at high pressure.

9.5B Carbon dioxide is liquid at 60 atm and 25° C. When it is released into a room at 1 atm and 25° C, as the pressure decreases, the

system reaches the liquid–vapor boundary, at which pressure the liquid is changed to vapor. The vaporization absorbs sufficient heat to cool the CO_2 to below its sublimation temperature at 1 atm. As a result, fine particles of solid CO_2 "snow" are produced.

9.6B Critical temperature increases with the strength of intermolecular forces. For example, CH_4 cannot form hydrogen bonds; so it has a lower critical temperature than either NH_3 or H_2O, which can form hydrogen bonds.

9.7B $s = (2.3 \times 10^{-2}\ \text{mol·L}^{-1}\text{·atm}^{-1})(1.00\ \text{atm}) = 2.3 \times 10^{-2}\ \text{mol·L}^{-1}$; $n(CO_2) = 0.900\ \text{L} \times (2.3 \times 10^{-2}\ \text{mol·L}^{-1}) = 0.021\ \text{mol}$

9.8B $\text{molality} = \dfrac{7.36\ \text{g KClO}_3}{0.200\ \text{kg H}_2\text{O}} \times \dfrac{1\ \text{mol KClO}_3}{122.55\ \text{g KClO}_3} = 0.300\ \text{mol·kg}^{-1}$

9.9B $x_{H_2O} = 1 - 0.250 = 0.750$; $0.750\ \text{mol H}_2\text{O} \times 18.02\ \text{g·mol}^{-1} \times 1\ \text{kg}/10^3\ \text{g} = 0.0135\ \text{kg}$; $b(H_2O) = 0.0135\ \text{kg H}_2\text{O}$; molality $=$

$$\frac{0.250\ \text{mol CH}_3\text{OH}}{0.0135\ \text{kg H}_2\text{O}} = 18.5\ \text{mol}\cdot\text{kg}^{-1}$$

9.10B Assume a 1 L solution; $m_{NaCl} = 1\ \text{L} \times \dfrac{1.83\ \text{mol NaCl}}{1\ \text{L soln}} \times 58.44\ \text{g·mol}^{-1} = 106.9\ \text{g NaCl}$; $m_{solution} = 1\ \text{L soln} \times \dfrac{10^3\ \text{mL}}{1\ \text{L}} \times \dfrac{1.07\ \text{g}}{1\ \text{mL}} = 1.07 \times 10^3\ \text{g}$; $m_{H_2O} = 1070\ \text{g} - 107\ \text{g} = 9.6 \times 10^3\ \text{g}$; $1.83\ \text{mol}/0.96\ \text{kg} = 1.9\ \text{mol·kg}^{-1}$

9.11B $n_{C_9H_8O} = 2.00\ \text{g} \times \dfrac{1\ \text{mol}}{132.16\ \text{g}} = 0.0151\ \text{mol}$;

$$n_{C_2H_5OH} = 50.0\ \text{g} \times \frac{1\ \text{mol}}{46.07\ \text{g}} = 1.09\ \text{mol};$$

$$x_{C_2H_5OH} = \frac{1.09\ \text{mol}}{(1.09 + 0.0151)\ \text{mol}} = 0.986;$$

$P = (0.986)(5.3\ \text{kPa}) = 5.2\ \text{kPa}$

9.12B $\Delta T_f = k_f m = (39.7\ \text{K·kg·mol}^{-1})(0.050\ \text{mol·kg}^{-1}) = 1.99\ \text{K} = 1.99°\text{C}$; $T_f = 179.8°\text{C} - 1.99°\text{C} = 177.8°\text{C}$

9.13B $i = 1$ since sucrose is a nonelectrolyte and does not dissociate; $(1)(0.08206\ \text{L·atm·mol}^{-1}\text{·K}^{-1})(298\ \text{K})\ (0.120\ \text{mol·L}^{-1}) = 2.93\ \text{atm}$

9.14B $b = 0.51\ \text{K}/39.7\ \text{kg·K·mol}^{-1} = 0.0128\ \text{mol·kg}^{-1}$; $n(\text{linalool}) = 0.100\ \text{kg} \times (0.0128\ \text{mol}/1\ \text{kg}) = 1.28 \times 10^{-3}\ \text{mol}$; $M = 0.200\ \text{g}/(1.28 \times 10^{-3}\ \text{mol}) = 156\ \text{g·mol}^{-1}$

9.15B $n = cV = \left(\dfrac{2.11\ \text{kPa}}{(1) \times (8.3145\ \text{L·kPa·K}^{-1}\text{·mol}^{-1}) \times (293\ \text{K})}\right) \times 0.175\ \text{L} = 1.52 \times 10^{-4}\ \text{mol}$;

$$M = \left(\frac{1.50\ \text{g}}{1.52 \times 10^{-4}\ \text{mol}}\right) = 9.87 \times 10^3\ \text{g}\cdot\text{mol}^{-1} = 9.87\ \text{kg}\cdot\text{mol}^{-1}$$

9.16B Equal masses; therefore, assume 50.00 g of each.

$$n_{C_6H_6} = 50.00\ \text{g} \times \frac{1\ \text{mol}}{78.11\ \text{g}} = 0.6401\ \text{mol};$$

$$n_{C_7H_8} = 50.00\ \text{g} \times \frac{1\ \text{mol}}{92.13\ \text{g}} = 0.5427\ \text{mol};$$

$$x_{C_6H_6} = \frac{0.6401\ \text{mol}}{(0.6401 + 0.5427)\ \text{mol}} = 0.5412;$$

$$x_{C_7H_8} = \frac{0.5427\ \text{mol}}{(0.6401 + 0.5427)\ \text{mol}} = 0.4588;$$

$P_{total} = (0.5412) \times (94.6\ \text{Torr}) + (0.4588) \times (29.1\ \text{Torr}) = 64.5\ \text{Torr}$

9.17B (a) $P = (0.500)(94.6\ \text{Torr}) + (0.500)(29.1\ \text{Torr}) = 61.8\ \text{Torr}$;

(b) $x_{C_6H_6,vap} = \dfrac{(0.500) \times (94.6\ \text{Torr})}{61.8\ \text{Torr}} = 0.765$; $x_{C_7H_8,vap} = 1 - 0.765 = 0.235$

Major Technique 4

MT4.1B HCl is in the mobile phase; the order of elution of the compounds will be the same as the order of their solubilities in HCl: $CuCl_2 > CoCl_2 > NiCl_2$.

Chapter 10

10.1B $K = (P_{SO_2})^2(P_{H_2O})^2/(P_{H_2S})^2(P_{O_2})^3$

10.2B $K = [ZnCl_2](P_{H_2})/[HCl]^2$

10.3B $K = 1/(P_{O_2})^5$

10.4B $\Delta G_r = 4.73\ \text{kJ·mol}^{-1} + (8.3145\ \text{J·mol}^{-1}\text{·K}^{-1})(298\ \text{K}) \times \ln\{(2.10)^2/0.80\} \times (1\ \text{kJ}/10^3\ \text{J}) = +8.96\ \text{kJ·mol}^{-1}$. Because $\Delta G > 0$, reaction proceeds toward reactants.

10.5B $\Delta G_r° = 2\Delta G_f°\ (NO_2(g)) - [\Delta G_f°\ (O_2(g)) + 2\Delta G_f°\ (NO(g))] = [2(51.31 - (0 + 2(86.55))]\ \text{kJ·mol}^{-1} = -70.48\ \text{kJ·mol}^{-1}$; $\ln K = -(-70.48 \times 10^3\ \text{J·mol}^{-1})/(8.3145\ \text{kJ·K}^{-1}\text{·mol}^{-1} \times 298\ \text{K}) = 28.45$; $K = 2.3 \times 10^{12}$

10.6B $52\ \text{kPa} \times (1\text{bar})/(10^2\ \text{kPa}) = 0.52\ \text{bar}$; $P_{NO} = [K \times P_{N_2} \times P_{O_2}]^{1/2} = [(3.4 \times 10^{-21}) \times (0.52\ \text{bar}) \times (0.52\ \text{bar})]^{1/2} = 3.0 \times 10^{-11}\ \text{bar}$, or $3.0 \times 10^{-6}\ \text{Pa}$

10.7B $Q = (1.2)^2/2.4 = 0.60$; $K = 0.15$, and so $Q > K$ and the partial pressure of N_2O_4 will increase.

10.8B $K_c = K(T/12.03\ \text{K})^{-\Delta n}$, $\Delta n = 2 - 1 = +1$; $K_c = (47.9) \times (12.03\ \text{K}/400.\ \text{K}) = 1.44$

10.9B $K_c = (7.3 \times 10^{-13})^{1/2} = 8.5 \times 10^{-7}$

10.10B $K = (2x)^2(x)/(0.012 - 2x)^2 \approx 4x^3/(0.012)^2 = 3.5 \times 10^{-32}$; $x = 1.1 \times 10^{-12}$. At equilibrium: $P_{HCl} = 0.012\ \text{bar}$; $P_{HI} = 2.2 \times 10^{-12}\ \text{bar}$; $P_{Cl_2} = 1.1 \times 10^{-12}\ \text{bar}$; some solid I_2 remains as well.

10.11B $Q = (0.100)^2/(0.200)(0.100) = 0.5$, so $Q < K$; $K = 20. = (0.100 + 2x)^2/[(0.200 - x)(0.100 - x)]$; $x = 0.0750\ \text{bar}$; $P_{ClF} = 0.100 + 2x = 0.250\ \text{bar}$

10.12B The equilibrium tends to shift toward (a) products; (b) products; (c) reactants.

10.13B $Q = (1.30)^2/(0.080)(0.050)^3 = 1.7 \times 10^5$; $Q < K$. $K = (1.30 + 2x)^2/(0.080 - x)(0.050 - x)^3 = 6.8 \times 10^5$; $x = 5.86 \times 10^{-3}\ \text{bar}$; 0.074 bar N_2; 1.31 bar NH_3; 0.032 bar H_2

10.14B Compression affects gaseous species only. In the forward reaction, 1 mol of $CO_2(g)$ reacts to form an aqueous species. Therefore, compression favors the formation of $H_2CO_3(aq)$.

10.15B $\Delta H r° = 2(-393.51\ \text{kJ·mol}^{-1}) - 2\ (-110.53\ \text{kJ·mol}^{-1}) - 0 = -565.96\ \text{kJ·mol}^{-1}$. The reaction is exothermic; therefore, lowering the temperature shifts the reaction to the products. The pressure of CO_2 will increase.

10.16B $\Delta H_r° = 0 + (-287.0\ \text{kJ·mol}^{-1}) - (-374.9\ \text{kJ·mol}^{-1}) = +87.9\ \text{kJ·mol}^{-1}$;

$$\ln\left(\frac{K_2}{K_1}\right) = \frac{87.9 \times 10^3\ \text{J}\cdot\text{mol}^{-1}}{8.3145\ \text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}}\left[\frac{1}{523\ \text{K}} - \frac{1}{800\ \text{K}}\right] = 7.0;$$

$K_2 = K_1 e^{7.0} = (78.3)e^{7.0} = 8.6 \times 10^4$

Chapter 11

11.1B (a) H_3O^+ (it has one more H^+ than H_2O); (b) NH_2^- (it has one less H^+ than NH_3)

11.2B (a) Brønsted acids: $NH_4^+(aq)$, $H_2CO_3(aq)$; Brønsted bases: $HCO_3^-(aq)$, $NH_3(aq)$; (b) Lewis acid: $H^+(aq)$; Lewis bases: $NH_3(aq)$, $HCO_3^-(aq)$

11.3B (a) $[H_3O^+] = (1.0 \times 10^{-14})/(2.2 \times 10^{-3}) = 4.5 \times 10^{-12}\ \text{mol·L}^{-1}$; (b) $[OH^-] = [NaOH]_{initial} = 2.2 \times 10^{-3}\ \text{mol·L}^{-1}$

11.4B $[OH^-] = [NaOH]_{initial} = 0.077\ \text{mol·L}^{-1}$; $[H_3O^+] = (1.0 \times 10^{-14})/(0.077) = 1.30 \times 10^{-13}\ \text{mol·L}^{-1}$; $\text{pH} = -\log(1.3 \times 10^{-13}) = 12.89$

11.5B $[H_3O^+] = 10^{-8.2} = 6 \times 10^{-9}\ \text{mol·L}^{-1}$

11.6B The conjugate base of HIO_3 is IO_3^-; $pK_b = pK_w - pK_a = 14.00 - 0.77 = 13.23$

11.7B (a) $1.8 \times 10^{-9} = K_b(C_5H_5N) < K_b(NH_2NH_2) = 1.7 \times 10^{-6}$, so NH_2NH_2 is the stronger base. (b) From part a, C_5H_5N is the weaker base, so $C_5H_5NH^+$ is the stronger acid. (c) $1.7 \times 10^{-1} = K_a(HIO_3) > K_a(HClO_2) = 1.0 \times 10^{-2}$, so HIO_3 is the stronger acid. (d) $K_b(HSO_3^-) = (1.0 \times 10^{-14})/(1.5 - 10^{-2}) = 6.7 \times 10^{-13}$; $K_b(ClO_2^-) = (1.0 \times 10^{-14})/(1.0 - 10^{-2}) = 1.0 \times 10^{-12}$; $K_b(HSO_3^-) < K_b(ClO_2^-)$; therefore, ClO_2^- is the stronger base.

11.8B $CH_3COOH < CH_2ClCOOH < CHCl_2COOH$ (The electronegativity of Cl is greater than that of H. Therefore, the acidity increases as the number of attached chlorine atoms increases.)

11.9B Check approximation: $K_a = 1.4 \times 10^{-3} = x^2/(0.22 - x)$, $x = 0.018$, $> 5\%$ of 0.22, so the quadratic equation is required: $x^2 + (1.4 \times 10^{-3})x - 3.1 \times 10^{-4} = 0$; $x = 1.7 \times 10^{-2}$ mol·L^{-1} = $[H_3O^+]$; pH = 1.77; percentage deprotonation = $[(1.7 \times 10^{-2})/0.22] \times 100\% = 7.7\%$

11.10B $[H_3O^+] = 10^{-2.35} = 4.5 \times 10^{-3}$ mol·L^{-1}; $K_a = (4.5 \times 10^{-3})^2/\{0.50 - (4.5 \times 10^{-3})\} = 4.1 \times 10^{-5}$

11.11B $K_b = 1.0 \times 10^{-6} = x^2/(0.012 - x) \approx x^2/.012$; $x = 1.1 \times 10^{-4} = [OH^-]$; pOH = 3.96; pH = 14.00 − 3.96 = 10.04; percentage protonated = $(1.1 \times 10^{-4})/(0.012) \times 100 = 0.92\%$

11.12B (a) CO_3^{2-} is the conjugate base of HCO_3^-, which is a weak acid; therefore, the solution is basic. (b) $K_a(Al(H_2O)_6^{3+}) = 1.4 \times 10^{-5}$; therefore, the solution is acidic. (c) K^+ is a "neutral cation" and NO_3^- is a conjugate base of a strong acid; therefore, the aqueous solution is neutral.

11.13B $NH_4^+(aq) + H_2O(l) \rightleftharpoons NH_3(aq) + H_3O^+(aq)$; $K_b(NH_3) = 1.8 \times 10^{-5}$; $K_a(NH_4^+) = (1.0 \times 10^{-14})/(1.8 \times 10^{-5}) = 5.6 \times 10^{-10}$; $K_a = 5.6 \times 10^{-10} = x^2/(0.10 - x) \approx x^2/0.10$; $x = 7.5 \times 10^{-6}$; pH = $-\log(7.5 \times 10^{-6}) = 5.12$

11.14B $F^-(aq) + H_2O(l) \rightleftharpoons HF(aq) + OH^-(aq)$; $K_a(HF) = 3.5 \times 10^{-4}$; $K_b(F^-) = (1.0 \times 10^{-14})/(3.5 \times 10^{-4}) = 2.9 \times 10^{-11}$; $K_b = 2.9 \times 10^{-11} = x^2/(0.020 - x) \approx x^2/0.020$; $x = 7.56 \times 10^{-7}$; pOH = 6.12; pH = 14.00 − 6.12 = 7.88

11.15B $0.012 = (0.10 + x)(x)/(0.10 - x)$; $x^2 + 0.11x - 0.0012 = 0$; from the quadratic formula, $x = 0.0098$; $[H_3O^+] = 0.10 + 0.0098 = 0.11$; pH = 0.96

11.16B $pK_{a1}(H_3PO_4) = 2.12$; $pK_{a2}(H_3PO_4) = 7.21$; pH = $\frac{1}{2}(2.12 + 7.21) = 4.66$

11.17B $[Cl^-] = 0.50$ mol·L^{-1}; $^+NH_3CH_2COOH(aq) + H_2O(l) \rightleftharpoons {}^+NH_3CH_2COO^-(aq) + H_3O^+(aq)$, $K_{a1} = 4.5 \times 10^{-3}$ but > 5% ionization, so approximation not valid, $x^2 + (4.5 \times 10^{-3})x - 0.00225 = 0$; $x = 0.045 = [H_3O^+] = [{}^+NH_3CH_2COO^-]$; $[{}^+NH_3CH_2COOH] = (0.50 - 0.045)$ mol·L^{-1} = 0.45 mol·L^{-1}; $^+NH_3CH_2COO^-(aq) + H_2O(l) \rightleftharpoons NH_2CH_2COO^-(aq) + H_3O^+(aq)$, $K_{a2} = 1.7 \times 10^{-10} = (x)(0.045)/(0.045 - x)$, $x = 1.7 \times 10^{-10}$ mol·L^{-1} = $[NH_2CH_2COO^-]$ (< 5% ionization, so approximation is valid); $[OH^-] = K_w/[H_3O^+] = (1.0 \times 10^{-14})/(0.045) = 2.2 \times 10^{-13}$ mol·L^{-1}

11.18B $K_w = [H_3O^+]([H_3O^+] + [NaOH]_{initial}) = x(x + [NaOH]_{initial})$, $x^2 + (2.0 \times 10^{-7})x - (1.0 \times 10^{-14})$, $x = 4.1 \times 10^{-8}$ mol·L^{-1}, pH = $-\log(4.1 \times 10^{-8}) = 7.39$

11.19B $K_a(HIO) = 2.3 \times 10^{-11}$, $x^3 + (2.3 \times 10^{-11})x^2 - [1.0 \times 10^{-14} + (2.3 \times 10^{-11})(1.0 \times 10^{-2}]x - (2.3 \times 10^{-11})(1.0 \times 10^{-14}) = 0$, $x^3 + (2.3 \times 10^{-11})x^2 - 2.4 \times 10^{-13})x - (2.3 \times 10^{-25}) = 0$, $x = 4.9 \times 10^{-7} = [H_3O^+]$, pH = $-\log(4.9 \times 10^{-7}) = 6.31$

Chapter 12

12.1B $K_a = 5.6 \times 10^{-10}$; pH = $-\log(5.6 \times 10^{-10}) + \log(0.030/0.040) = 9.13$

12.2B $n(CH_3CO_2^-)_{final} = [(0.500\text{ L}) \times (0.040\text{ mol·L}^{-1})] - 0.0100$ mol = 0.0100 mol, $[CH_3CO_2^-]_{final} = (0.0100\text{ mol})/(0.500\text{ L}) = 0.0200$ mol·L^{-1}; $n(CH_3COOH)_{final} = [(0.500\text{ L}) \times (0.080\text{ mol·L}^{-1})] + 0.0100$ mol = 0.0500 mol, $[CH_3COOH]_{final} = (0.0500\text{ mol})/(0.500\text{ L}) = 0.100$ mol·L^{-1}; pH = 4.75 + log(0.0200/0.100) = 4.05; $pH_{final} - pH_{initial} = 4.05 - 4.45 = -0.4$ (a decrease of 0.4)

12.3B $(CH_3)_3NH^+/(CH_3)_3N$, because the $pK_a = 9.81$, which is close to 10

12.4B pH − pK_a = 3.50 − 4.19 = −0.69; $([C_6H_5CO_2^-]/[C_6H_5COOH]) = 10^{-0.69} = 0.20{:}1$

12.5B Amount of H_3O^+ added = 0.012 L × (0.340 mol)/1 L = 0.00408 mol; amount of OH^- remaining = 0.00625 − 0.00408 mol = 0.00217 mol, $[OH^-]$ = (0.00217 mol)/(0.0370 L) = 0.0586 mol·L^{-1}; pOH = 1.232; pH = 14.00 − 1.232 = 12.77

12.6B initial amount of NH_3 = 0.025 L × (0.020 mol·L^{-1}) = 5.0×10^{-4} mol; volume of HCl added = $(5.0 \times 10^{-4}\text{ mol})/(0.015\text{ mol·L}^{-1})$ = 0.0333 L; $[NH_4^+] = (5.0 \times 10^{-4}\text{ mol})/(0.0333 + 0.02500)$ L = 0.0086 mol·L^{-1}; $K_a = [H_3O^+][NH_3]/[NH_4^+] = 5.6 \times 10^{-10} = (x^2)/(0.0086 - x) \approx (x^2)/(0.0086)$; $[H_3O^+] = x = 2.2 \times 10^{-6}$; pH = 5.66

12.7B final volume of solution = 25.00 + 15.00 mL = 40.00 mL; amount of HCO_2^- formed = amount of OH^- added = (0.150 mol·L^{-1}) × (15.00 mL) = 2.25 mmol; amount of HCOOH remaining = 2.50 − 2.25 mmol = 0.25 mmol; [HCOOH] = $(0.25 \times 10^{-3}\text{ mol})/(0.04000\text{ L})$ = 0.062 mol·L^{-1}; $[HCO_2^-] = (2.25 \times 10^{-3}\text{ mol})/(0.04000\text{ L})$ = 0.0562 mol·L^{-1}; pH = 3.75 + log(0.0562/0.0062) = 4.71

12.8B (a) amount of H_3PO_4 = (0.030 L)(0.010 mol·L^{-1}) = 3.0×10^{-4} mol; at first stoichiometric point, initial amount of H_3PO_4 = amount of NaOH added; volume of NaOH = 3.0×10^{-4} mol/ 0.020 mol·L^{-1} = 0.015 L, or 15 mL. (b) 2 ×15 mL = 30. mL

12.9B (0.020 L)(0.100 mol·L^{-1}) = 0.0020 mol H_2S; 0.0020 mol/ (0.300 mol·L^{-1}) = 0.0067 L, or 6.7 mL NaOH for first stoichiometric point and 2 × 6.7 mL = 13.4 mL for second stoichiometric point; (a) before first stoichiometric point; primary species present are Na^+, H_2S, and HS^-; (b) at second stoichiometric point, primary species present are Na^+ and S^{2-} (also HS^- and OH^- because S^{2-} has a relatively large K_b)

12.10B $K_{sp} = [Ag^+][Br^-] = (8.8 \times 10^{-7})^2 = 7.7 \times 10^{-13}$

12.11B $K_{sp} = [Pb^{2+}][F^-]^2 = (s)(2s)^2 = 4s^3$; $3.7 \times 10^{-8} = 4s^3$; $s = 2.1 \times 10^{-3}$ mol·L^{-1}

12.12B In 0.10 M $CaBr_2$(aq), $[Br^-]$ = 2 × (0.10 mol·L^{-1}) = 0.20 mol·L^{-1}; $s = [Ag^+] = K_{sp}/[Br^-] = (7.7 \times 10^{-13})/(0.20) = 3.8 \times 10^{-12}$ mol·L^{-1}

12.13B $[Ba^{2+}] = \{(1.0 \times 10^{-3}\text{ mol·L}^{-1}) \times (100\text{ mL})\}/300\text{ mL} = 3.3 \times 10^{-4}$ mol·L^{-1}. $[F^-] = \{(1.0 \times 10^{-3}\text{ mol·L}^{-1}) \times (200\text{ mL})\}/300\text{ mL} = 6.7 \times 10^{-4}$ mol·L^{-1}. $Q_{sp} = (3.3 \times 10^{-4})(6.7 \times 10^{-4})^2 = 1.5 \times 10^{-10} < K_{sp} = 1.7 \times 10^{-6}$; therefore, no precipitate of BaF_2 forms.

12.14B (a) For $PbCl_2$ to precipitate, $[Cl^-] = (K_{sp}/[Pb^{2+}])^{1/2} = (1.6 \times 10^{-5}/0.020)^{1/2} = 2.8 \times 10^{-2}$ mol·L^{-1}. For AgCl to precipitate, $[Cl^-] = (K_{sp}/[Ag^+]) = (1.6 \times 10^{-10}/0.0010) = 1.6 \times 10^{-7}$ mol·L^{-1}. Therefore, AgCl precipitates first at $[Cl^-] = 1.6 \times 10^{-7}$ mol·L^{-1}, then $PbCl_2$ precipitates at $[Cl^-] = 2.8 \times 10^{-2}$ mol·L^{-1}. (b) When the $PbCl_2$ precipitates, $[Ag^+] = (K_{sp}/[Cl^-]) = (1.6 \times 10^{-10})/(2.8 \times 10^{-2}) = 5.7 \times 10^{-9}$ mol·L^{-1}.

12.15B $CuS(s) + 4\,NH_3(aq) \rightleftharpoons Cu(NH_3)_4^{2+}(aq) + S^{2-}(aq)$; $K = (1.3 \times 10^{-36}) \times (1.2 \times 10^{13}) = 1.6 \times 10^{-23}$; $K = [Cu(NH_3)_4^{2+}][S^{2-}]/[NH_3]^4 = 1.6 \times 10^{-23} = x^2/(1.2 - 4x)^4 \approx x^2/(1.2\,)^4$; $x/(1.2)^2 = 4.0 \times 10^{-12}$; $x = [S^{2-}] = 5.8 \times 10^{-12}$ mol·L^{-1}

Chapter 13

13.1B reduction: $(8\,H^+ + MnO_4^- + 5\,e^- \longrightarrow Mn^{2+} + 4\,H_2O) \times 2$; oxidation: $(H_2O + H_2SO_3 \longrightarrow HSO_4^- + 2\,e^- + 3\,H^+) \times 5$; net reaction: $H^+(aq) + 2\,MnO_4^-(aq) + 5\,H_2SO_3(aq) \longrightarrow 2\,Mn^{2+}(aq) + 5\,HSO_4^-(aq) + 3\,H_2O(l)$

13.2B oxidation: $(3\,I^- \longrightarrow I_3^- + 2\,e^-) \times 8$; reduction: $9\,H_2O + 16\,e^- + 3\,IO_3^- \longrightarrow I_3^- + 18\,OH^-$; net reaction: $3\,H_2O(l) + IO_3^-(aq) + 8\,I^-(aq) \longrightarrow 3\,I_3^-(aq) + 6\,OH^-(aq)$

13.3B Half reactions for the silver battery in Table 13.2 show that $n = 2$; $\Delta G = -(2\text{ mol})(9.6485 \times 10^4\text{ C·mol}^{-1})(1.6\text{ V}) = -3.09 \times 10^5$ C·V·mol^{-1} = -3.1×10^2 kJ.

13.4B $Mn(s)|Mn^{2+}(aq)||Cu^{2+}(aq),Cu^+(aq)|Pt(s)$

13.5B (a) left: $2\,Hg(l) + 2\,HCl(aq) \longrightarrow Hg_2Cl_2(s) + 2\,e^-$; right: $2\,e^- + Hg_2(NO_3)_2(aq) \longrightarrow 2\,Hg(l) + 2\,NO_3^-(aq)$; $2\,HCl(aq) + Hg_2(NO_3)_2(aq) \longrightarrow Hg_2Cl_2(s) + 2\,HNO_3(aq)$. (b) yes

13.6B $E°(Pb^{2+}/Pb) = E°_{cell} + E°(Fe^{2+}/Fe) = 0.31\text{ V} + (-0.44\text{ V}) = -0.13$ V

13.7B $Mn^{3+} + e^- \longrightarrow Mn^{2+}$, $E°_1 = +1.51$ V; $Mn^{2+} + 2e^- \longrightarrow Mn(s)$, $E°_2 = -1.18$ V; net half-reaction: $Mn^{3+} + 3\,e^- \longrightarrow Mn(s)$, $E°_3 = [(n_1E_1 + n_2E_2)/(n_3)] = [(1\text{ mol})(1.51\text{ V}) + (2\text{ mol})(-1.18\text{ V})]/(3\text{ mol}) = -0.28$ V

13.8B $O_2 + 2\,H_2O + 4e^- \longrightarrow 4\,OH^-$, $E° = +0.40$ V; $Cl_2 + 2\,e^- \longrightarrow 2\,Cl^-$, $E° = +1.36$ V. Yes, $Cl_2(g)$ can oxidize H_2O to $O_2(g)$ in basic solution under standard conditions because the Cl_2 reduction half-reaction has a more positive standard potential than the O_2 reduction half-reaction.

13.9B oxidation half-reaction: $Cu^{2+} + 2\,e^- \longrightarrow Cu$, $E° = +0.34$ V; reduction half-reaction: $Ag^+ + e^- \longrightarrow Ag$, $E° = +0.80$ V; net reaction: $Cu(s) + 2\,Ag^{2+}(aq) \longrightarrow Cu^{2+}(aq) + 2\,Ag(s)$, $E° = +0.46$ V. Therefore, Ag^+ is the stronger oxidizing agent. $Cu(s)|Cu^{2+}(aq)\|Ag^+(aq)|Ag(s)$

13.10B $Cd(OH)_2 + 2\,e^- \longrightarrow Cd + 2\,OH^-$, $E° = -0.81$ V; $Cd^{2+} + 2\,e^- \longrightarrow Cd$, $E° = -0.40$ V; net: $Cd(OH)_2(s) \longrightarrow Cd^{2+}(aq) + 2\,OH^-(aq)$, $E° = -0.41$ V; $\ln K_{sp} = (2)(-0.41\text{ V})/0.025693\text{ V} = -31.92$; $K_{sp} = 1.4 \times 10^{-14}$

13.11B cell reaction: $Ag^+(aq, 0.010\text{ mol·L}^{-1}) \longrightarrow Ag^+(aq, 0.0010\text{ mol·L}^{-1})$, $E° = 0.0$ V, $n = 1$; $E = 0.0\text{ V} - (0.025693\text{ V}) \times \ln(0.0010/0.010) = +0.059$ V

13.12B At pH = 12.5, pOH = 1.5 and $[OH^-] = 10^{-1.5} = 0.032\text{ mol·L}^{-1}$; $[Ag^+] = (K_{sp}/[OH^-]) = (1.5 \times 10^{-8}/(0.032)) = 4.7 \times 10^{-7}\text{ mol·L}^{-1}$. $E = -(0.025693\text{ V}/1)\ln(4.7 \times 10^{-7}/1.0) = 0.37$ V

13.13B The reduction half-reactions are: $Br_2(l) + 2\,e^- \longrightarrow 2\,Br^-(aq)$, $E° = +1.09$ V; $O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2H_2O\,(l)$, $E = +0.82$ V at pH = 7; $2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g)$, $E° = 0.00$ V. Product at the cathode: H_2; product at the anode: O_2 and Br_2. (We predict that H_2O will be oxidized rather than Br^-. However, because of the high overpotential for oxygen production, bromine may also be produced.)

13.14B 12.0 mol e^- × (1 mol Cr)/(6 mol e^-) = 2 mol Cr

13.15B $$m_{Cr} = \frac{(6.20\text{ C}\cdot\text{s}^{-1})(6.00\text{ h} \times 3600\text{ s}\cdot\text{h}^{-1})}{9.6485 \times 10^4\text{ C}\cdot\text{mol}^{-1}} \times \frac{1\text{ mol Cr}}{6\text{ mol e}^-} \times \frac{52.00\text{ g Cr}}{1\text{ mol Cr}} = 12.0\ g\ Cr$$

13.16B $$12.00\text{ g Cr} \times \frac{1\text{ mol Cr}}{52.00\text{ g Cr}} \times \frac{6\text{ mol e}^-}{1\text{ mol Cr}} = 1.385\text{ mol e}^-;$$
$$t = \frac{(1.385\text{ mol e}^-)(9.6485 \times 10^4\text{ C}\cdot\text{mol}^{-1})}{6.20\text{ C}\cdot\text{s}^{-1}} \times \frac{1\text{ h}}{3600\text{ s}} = 5.99\text{ h}$$

13.17B (b) Aluminum. It is the only one of the metals with a standard potential (−1.66 V) lower than that of iron (+0.44 V), so it is the only one more easily oxidized than iron.

Chapter 14

14.1B average rate of disappearance of Hb =
$$\frac{-[(8.0 \times 10^{-7}) - (1.2 \times 10^{-6})](\text{mmol Hb})\cdot\text{L}^{-1}}{0.10\ \mu\text{s}} = 4 \times 10^{-6}\text{ mmol}\cdot\text{L}^{-1}\cdot\mu\text{s}^{-1}$$

14.2B (a) ½[5.0×10^{-3} (mmol HI)·L^{-1}·s^{-1}] = 2.5×10^{-3} (mmol H_2)·L^{-1}·s^{-1}; (b) unique average rate = $\Delta[H_2]/\Delta t = \Delta[I_2]/\Delta t = -½(\Delta[HI]/\Delta t) = 2.5 \times 10^{-3}$ mmol·L^{-1}·s^{-1}

14.3B (a) first order in C_4H_9Br; zero order in OH^-; (b) first order overall; (c) s^{-1}

14.4B rate = $k\,[CO]^m\,[Cl_2]^n$
$$\frac{\text{rate (2)}}{\text{rate (1)}} = \frac{0.241}{0.121} = \left(\frac{0.24}{0.12}\right)^m\left(\frac{0.20}{0.20}\right)^n;\ 2 = (2)^m;\ m = 1;$$
$$\frac{\text{rate (3)}}{\text{rate (2)}} = \frac{0.682}{0.241} = \left(\frac{0.24}{0.24}\right)^m\left(\frac{0.40}{0.20}\right)^n;\ 2.8 = (2)^n;\ n = \frac{\log 2.8}{\log 2} = 1.5;$$
Therefore, rate = $k\,[CO][Cl_2]^{3/2}$. From experiment 1,
$$k = \frac{0.121\text{ mol·L}^{-1}\text{·s}^{-1}}{(0.12\text{ mol·L}^{-1})(0.20\text{ mol·L}^{-1})^{3/2}} = 11\text{ L}^{3/2}\text{·mol}^{-3/2}\text{·s}^{-1}$$

14.5B $[C_3H_6]_t = [C_3H_6]_0\,e^{-kt} = (0.100\text{ mol·L}^{-1})[e^{-(6.7 \times 10^{-4}\cdot\text{s}^{-1})(200\text{ s})}] = 0.087\text{ mol·L}^{-1}$

14.6B A plot of $\ln(CH_3N_2CH_3)$ against time is linear, showing that the reaction must be first order; $k = 3.60 \times 10^{-4}\text{ s}^{-1}$.

14.7B Reaction is first order with $k = 6.7 \times 10^{-4}\text{ s}^{-1}$ at 500° C;
$$t = \frac{1}{k}\ln\frac{[C_3H_6]_0}{[C_3H_6]_t} = \frac{1}{6.7 \times 10^{-4}\text{s}^{-1}}\ln\left(\frac{1.0\text{ mol}\cdot\text{L}^{-1}}{0.0050\text{ mol}\cdot\text{L}^{-1}}\right) = 7.9 \times 10^3\text{ s} = 2.2\text{ h}$$

14.8B $$k = \frac{\ln 2}{2.4 \times 10^4\text{ y}};\ t = \frac{2.4 \times 10^4\ y}{\ln 2}\left[\ln\left(\frac{1.0}{0.20}\right)\right] = 5.6 \times 10^4\text{ y}$$

14.9B (a) Four half-lives are required for the concentration to fall to one-sixteenth of its initial value: $(1/2)^4 = 1/16$; (b) The reaction is first order with $k = 5.5 \times 10^{-4}\text{ s}^{-1}$ at 973 K. $t_{1/2} = (\ln 2)/k = (\ln 2)/(5.5 \times 10^{-4}\text{ s}^{-1}) = 1.3 \times 10^3\text{ s} = 21$ min. $t = 4t_{1/2} = 4 \times 21\text{ min} = 84$ min.

14.10B (a) bimolecular (two reactants); (b) unimolecular (one reactant)

14.11B net rate$_{\text{disappearance of B}} = k_1[H_2A][B] + k_2[HA^-][B] - k_1'[HA^-][BH^+]$;
net rate$_{\text{formation of HA}^-} = k_1[H_2A][B] - k_1'[HA^-][BH^+] - k_2[HA^-][B] = 0$; $[HA^-] = (k_1[H_2A][B])/(k_1'[BH^+] + k_2[B])$;
substitute for $[HA^-]$: net rate$_{\text{disappearance of B}}$ =
$$k_1[H_2A][B] + \frac{(k_2k_1[H_2A][B]^2)}{k_1'[BH^+] + k_2[B]} - \frac{k_1'k_1[H_2A][B][BH^+]}{k_1'[BH^+] + k_2[B]};$$
assume $k_2[B] \ll k_1'[BH^+]$; then net rate$_{\text{disappearance of B}}$ = $k[H_2A][B]^2[BH^+]^{-1}$; $k = (2k_2k_1)/k_1'$; $H_2A + 2\,B \longrightarrow 2\,BH^+ + A^{2-}$

14.12B $$\ln\left(\frac{k'}{k}\right) = \frac{E_a}{R}\left[\frac{1}{T} - \frac{1}{T'}\right];\ \ln\left(\frac{4.35}{3.00}\right) = \frac{E_a}{8.3145\text{ J·mol}^{-1}\text{·}K^{-1}}\left[\frac{1}{291\text{ K}} - \frac{1}{303\text{ K}}\right];$$
$E_a = 2.3 \times 10^4\text{ J·mol}^{-1} = 23\text{ kJ·mol}^{-1}$

14.13B $$\ln\left(\frac{k'}{k}\right) = \frac{E_a}{R}\left[\frac{1}{T} - \frac{1}{T'}\right];\ \ln\left(\frac{k'}{k}\right) = \frac{2.72 \times 10^5\text{ J·mol}^{-1}}{8.3145\text{ J·mol}^{-1}\text{·K}^{-1}}\left[\frac{1}{773} - \frac{1}{573}\right] = -14.77\ k'/k =$$
$e^{-14.77}$; $k' = (6.7 \times 10^{-4}\text{ s}^{-1})(e^{-14.77}) = 2.6 \times 10^{-10}\text{ s}^{-1}$

14.14B (a) The homogeneous catalyst changes the reaction pathway, and therefore changes the rate law. (b) Since a catalyst does not change the thermodynamics of the reaction, a homogeneous catalyst does not change the equilibrium constant.

Chapter 15

15.1B Oxygen. It is above both gallium and tellurium in the periodic table and to the right of gallium.

15.2B Aluminum forms an amphoteric oxide in which it has the oxidation state +3; therefore, aluminum is the element.

15.3B Hydrogen is a nonmetal and a diatomic gas at room temperature. It has an intermediate electronegativity ($\chi = 2.2$), so it forms covalent bonds with nonmetals and forms anions in combination with metals. In contrast, Group 1 elements are solid metals that have low electronegativities and form cations in combination with nonmetals.

15.4B $K(s) + O_2(g) \longrightarrow KO_2(s)$

15.5B The molar mass of potassium is smaller than that of cesium. Thus the same amount of O_2 can be obtained from a smaller mass of KO_2 than can be obtained from a larger mass of CsO_2.

15.6B $2\,Ba(s) + O_2(g) \longrightarrow 2\,BaO(s)$

15.7B Lewis acid–base reaction; CaO is the base and SiO_2 is the acid.

15.8B Boric acid acts as a Lewis acid. The boron atom in $B(OH)_3$ has an incomplete octet and forms a bond by accepting a lone pair of electrons from a water molecule, which is acting as a Lewis base. The complex formed is a weak Brønsted acid in which an acidic proton can be lost from an H_2O molecule in the complex.

15.9B (a) +3, because the oxidation number of H in this hydride is taken to be −1; (b) +3

15.10B Lewis acid–base reaction; CO is the Lewis acid and OH^- is the Lewis base.

15.11B SiH_4 is a Lewis acid that can react with the Lewis base OH^-. CH_4 is not a Lewis acid, because the C atom is much smaller than the Si atom and has no accessible d-orbitals to accommodate added electron pairs.

15.12B (a)  ;

(b) Other resonance structures violate the octet rule, so the one shown in (a) is the major resonance contributor. (c) The azide ion is linear and nonpolar.

15.13B Assume 1 L solution; 1 L soln × (10^3 mL/1 L) × (1.7 g soln/1 mL soln) × (85 g H_3PO_4/100 g soln) × (1 mol H_3PO_4/97.99 g H_3PO_4) = 15 M H_3PO_4(aq)

15.14B Reduction: 2 ($2\,e^- + F_2 \longrightarrow 2\,F^-$); oxidation: $2\,H_2O \longrightarrow O_2 + 4\,H^+ + 4\,e^-$; overall: $2\,H_2O(l) + 2\,F_2(g) \longrightarrow O_2(g) + 4\,H^+(aq) + 4\,F^-(aq)$; $E° = 2.87 - 1.23\text{ V} = +1.64\text{ V}$; $\Delta G° = -(4\text{ mol})(96.485\text{ kC·mol}^{-1})(1.64\text{ V}) = -633\text{ kJ}$

15.15B (a) +1; (b) +6

15.16B The melting and boiling points of the halogens increase down the group because the intermolecular attractions become stronger; London forces become stronger as the number of electrons present increase.

15.17B In the reduction of $HClO_3$ an acid is a reactant. Therefore, increasing the pH reduces the oxidizing ability of $HClO_3$.

15.18B square pyramidal

Chapter 16

16.1B Each metal atom will lose one 4s-electron. V^+, Mn^+, Co^+, and Ni^+ will have one electron in the 4s-orbital, but Cr^+ and Cu^+ will have zero electrons in the 4*s*-orbital. Because their outermost valence electrons will be in 3d-orbitals and not the 4s-orbital, their radii should be smaller than the other cations.

16.2B Oxidation: $2\,Hg(l) \longrightarrow Hg_2^{2+}(aq) + 2\,e^-$; reduction: $4\,H^+(aq) + NO_3^-(aq) + 3\,e^- \longrightarrow NO(aq) + 2\,H_2O(l)$; overall: $6\,Hg(l) + 8\,H^+(aq) + 2\,NO_3^-(aq) \longrightarrow 3\,Hg_2^{2+}(aq) + 2\,NO(aq) + 4\,H_2O(l)$; $E° = 0.96\text{ V} - 0.79\text{ V} = +0.17\text{ V}$

16.3B (a) pentaaminebromidocobalt(II) sulfate; (b) $[Cr(NH_3)_4(OH_2)_2]Br_3$

16.4B The ratio of $CrCl_3·6H_2O$ to Cl is 1:3; therefore, the isomer $[Cr(OH_2)_6]Cl_3$ is present.

16.5B (a) NCS^- is replaced by SCN^-; linkage isomers; (b) H_2O is exchanged for Cl^-; hydrate isomers.

16.6B (a) not chiral; (b) chiral; (c) not chiral; (d) chiral; no enantiomeric pairs

16.7B $\Delta_O = hc/\lambda = (6.022 \times 10^{23}\text{ mol}^{-1})(6.626 \times 10^{-34}\text{ J·s}^{-1})(2.998 \times 10^8\text{ m·s}^{-1})/(305 \times 10^{-9}\text{ m}) \times (1\text{ kJ}/10^3\text{ J}) = 392\text{ kJ·mol}^{-1}$

16.8B (a) Strong-field ligands have large Δ_O. The configuration is $t_{2g}^6e_g^1$ and there is one unpaired electron. (b) Weak-field ligands have small Δ_O. The configuration is $t_{2g}^5e_g^2$ and there are three unpaired electrons.

16.9B The ligand en is strong-field, and H_2O is a weak-field ligand. However, because Ni^{2+} has eight d-electrons it is a d^8 complex and there is no empty e_g orbital. Therefore, both $[Ni(en)_3]^{2+}$ and $[Ni(H_2O)_6]^{2+}$ have a $t_{2g}^6e_g^2$ configuration, and are paramagnetic.

Chapter 17

17.1B (a) ${}^{232}_{90}Th \longrightarrow {}^{A}_{Z}E + {}^{4}_{2}\alpha$; ${}^{228}_{88}Ra$ is produced. (b) ${}^{228}_{88}Ra \longrightarrow {}^{A}_{Z}E + {}^{0}_{-1}e$; ${}^{228}_{89}Ac$ is produced.

17.2B (a) ${}^{55}_{26}Fe + {}^{0}_{-1}e \longrightarrow {}^{A}_{Z}E$; ${}^{55}_{25}Mn$ is produced. (b) ${}^{11}_{6}C \longrightarrow {}^{A}_{Z}E + {}^{0}_{+1}e$; ${}^{11}_{5}B$ is produced.

17.3B (c) Ce-148 is neutron rich (in the blue band) and therefore might undergo β emission, which converts a neutron into a proton, to reach stability.

17.4B (a) mass number: $250 + A = 257 + 4(1)$, $A = 11$; atomic number: $98 + Z = 103 + 4(0)$, $Z = 5$; the missing nuclide is ${}^{11}_{5}B$. (b) mass number: $A + 12 = 254 + 4(1)$, $A = 246$; atomic number: $Z + 6 = 102 + 4(0)$, $Z = 96$; the missing nuclide is ${}^{246}_{96}Cm$.

17.5B $m = m_0e^{-kt} = (5.0\ \mu g)e^{-(3.3\times10^{-7}a^{-1})(1.0\times10^{6}\ a)} = 3.6\ \mu g$

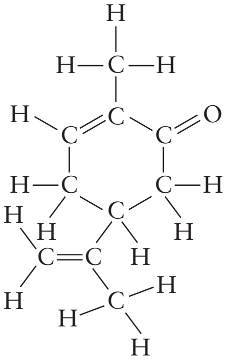
17.6B $t = -\left(\dfrac{5.73 \times 10^3\text{ y}}{\ln 2}\right) \times \ln\left(\dfrac{1.4 \times 10^4}{18400}\right) = 2.3 \times 10^3\text{ y}$

17.7B $\Delta m = \{(235.0439m_u) - 92(1.0078m_u) - 143(1.0087m_u)\} \times (1.6605 \times 10^{-27}\text{ kg}) = -3.1845 \times 10^{-27}\text{ kg}$; $E_{bind} = |3.1845 \times 10^{-27}\text{ kg}| \times (3.00 \times 10^8\text{ m·s}^{-1})^2 \times (1\text{ eV})/(1.60218 \times 10^{-19}\text{ J}) = 1.79 \times 10^9\text{ eV}$

17.8B $\Delta m = \{137.91m_u + 85.91m_u + 12(1.0087m_u) - (235.04m_u + 1.0087m_u)\} \times 1.6605 \times 10^{-27}\text{ kg} = -2.06 \times 10^{-28}$ kg per nucleus; $\Delta E = (1.0 \times 10^{-3}\text{ kg})/(235.0 \times 1.6605 \times 10^{-27}\text{ kg}) \times (-2.06 \times 10^{-28}\text{ kg}) \times (3.00 \times 10^8\text{ m·s}^{-1})^2 = -4.8 \times 10^{10}\text{ J}$

Chapter 18

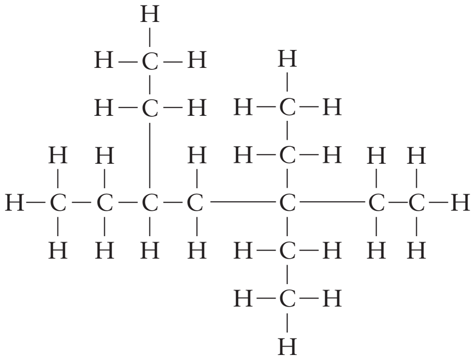
18.1B (a)



(b) $(CH_3)_2CH(CH_2)_3CH(CH_3)CH_2CH_3$

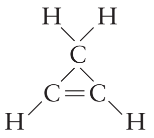
18.2B (a) 4-ethyl-2-methylhexane;

(b)



18.3B (a) 4-ethyl-2-hexene;

(b)



18.4B $CH_3(CH_2)_2CH_2Br$; $CH_3CH_2CHBrCH_3$; $(CH_3)_2CHCH_2Br$; $(CH_3)_3CBr$

18.5B 27a and 27b are both trans.
18.6B (c) is chiral, because the second C atom is attached to four different groups.
18.7B (a) has the higher boiling point because it has a longer chain than (b), and therefore has stronger London forces.
18.8B $CH_3CHClCH_2CH_3$
18.9B 1-ethyl-3,5-dimethyl-2-propylbenzene

Chapter 19

19.1 B (a) $HCOOCH_2CH_3$; (b) CH_3OH and $CH_3(CH_2)_2COOH$
19.2B C: sp^2 hybridization ; N: sp^3 hybridization
19.3B (a) 3-pentanol; (b) 3-pentanone; (c) ethylmethylamine
19.4B (a) $CH_2{=}C(CH_3)COOCH_3$;
(b) $—NHCH(CH_3)CO—NHCH(CH_3)CO—$
19.5B The A and B monomers alternate; therefore, —ABABAB— copolymer is an alternating copolymer.

Odd-Numbered Exercises

Fundamentals

A.1 (a) chemical; (b) physical; (c) physical

A.3 The temperature of the injured camper, the evaporation and condensation of water are physical properties. The ignition of propane is a chemical change.

A.5. (a) physical; (b) chemical; (c) chemical

A.7 (a) intensive; (b) intensive; (c) extensive; (d) extensive

A.9 (a) 1 kilograin; (b) 1 centibatman; (c) 1 megamutchkin

A.11 236 mL

A.13 19.3 $g{\cdot}cm^{-3}$

A.15 0.0427 cm^3

A.17 0.8589 $g{\cdot}cm^{-3}$

A.19 7.41 cm

A.21 3 (0.989)

A.23 (a) 4.82×10^3 pm; (b) 30.5 $mm^3{\cdot}s^{-1}$; (c) 1.88×10^{-12} kg; (d) 2.66×10^3 $kg{\cdot}m^{-3}$; (e) 0.044 $mg{\cdot}cm^{-3}$

A.25 (a) 1.72 $g{\cdot}cm^{-3}$ (more precise); (b) 1.7 $g{\cdot}cm^{-3}$

A.27 (a) formula: $X = 50 + 2°C$; (b) 94°X

A.29 32 J

A.31 4.0×10^3 kJ; 150 m

A.33 6.0 J

A.35 Since $R = R_E + h$,

$$E_P = \Delta E_P = \frac{-Gm_Em}{R_E + h} - \left(\frac{-Gm_Em}{R_E}\right)$$

$$= \frac{-Gm_Em}{R_E}\left(\frac{1}{1 + \frac{h}{R_E}} - 1\right) = \frac{Gm_Em}{R_E}\left(1 - \frac{1}{1 + \frac{h}{R_E}}\right)$$

If $x = \frac{h}{R_E}$, then

$$\frac{1}{1 + \frac{h}{R_E}} \approx 1 - \frac{h}{R_E}$$

from the expansion in x. Then

$$E_P = \frac{Gm_Em}{R_E}\left(1 - \left(1 - \frac{h}{R_E}\right)\right) = \frac{Gm_Emh}{{R_E}^2} = mgh$$

where $g = \frac{Gm_E}{{R_E}^2}$

B.1 1.40×10^{22} atoms

B.3 (a) 5p, 6n, 5e; (b) 5p, 5n, 5e; (c) 15p, 16n, 15e; (d) 92p, 146n, 92e

B.5 (a) ^{194}Ir; (b) ^{22}Ne; (c) ^{51}V

B.7 chlorine, ^{36}Cl, 17, 19, 17, 36; zinc, ^{65}Zn, 30, 35, 30, 65; calcium, ^{40}Ca, 20, 20, 20, 40; lanthanum, ^{137}La, 57, 80, 57, 137

B.9 (a) They all have the same mass. (b) They have differing numbers of protons, neutrons, and electrons.

B.11 (a) 0.5519; (b) 0.4479; (c) 2.459×10^{-4}; (d) 551.9 kg

B.13 (a) Scandium is a Group 3 metal. (b) Strontium is a Group 2 metal. (c) Sulfur is a Group 16/VI nonmetal. (d) Antimony is a Group 15/V metalloid.

B.15 (a) Sr, metal; (b) Xe, nonmetal; (c) Si, metalloid

B.17 fluorine, F, $Z = 9$, gas; chlorine, Cl, $Z = 17$, gas; bromine, Br, $Z = 35$, liquid; iodine, I, $Z = 53$, solid

B.19 (a) d-block; (b) p-block; (c) d-block; (d) s-block; (e) p-block; (f) d-block

B.21 The element is Pb. It is located in Group 14/IV and Period 6. It is a metal.

C.1 (a) mixture, one compound and one element; (b) single element

C.3 $C_{40}H_{56}O_2$

C.5 (a) $C_3H_7O_2N$; (b) C_2H_7N

C.7 (a) cation, Cs^+; (b) anion, I^-; (c) Se^{2-}; (d) Ca^{2+}

C.9 (a) 4 p, 6 n, 2 e; (b) 8 p, 9 n, 10 e; (c) 35 p, 45 n, 36 e; (d) 33 p, 42 n, 36 e

C.11 (a) $^{19}F^-$; (b) $^{24}Mg^{2+}$; (c) $^{128}Te^{2-}$; (d) $^{86}Rb^+$

C.13 (a) Al_2Te_3; (b) MgO; (c) Na_2S; (d) RbI

C.15 (a) Group 13/III; (b) aluminum, Al

C.17 (a) 0.542; (b) 0.458; (c) 2.49×10^{-4}; (d) 14 kg

C.19 (a) Na_2HPO_3; (b) $(NH_4)_2CO_3$; (c) +2; (d) +2

C.21 (a) molecular compound; (b) element; (c) ionic compound; (d) element; (e) molecular compound; (f) ionic compound

D.1 (a) $MnCl_2$; (b) $Ca_3(PO_4)_2$; (c) $Al_2(SO_3)_3$; (d) Mg_3N_2

D.3 (a) calcium phosphate; (b) tin(IV) sulfide, stannic sulfide; (c) vanadium(V) oxide; (d) copper(I) oxide, cuprous oxide

D.5 (a) TiO_2; (b) $SiCl_4$; (c) CS_2; (d) SF_4; (e) Li_2S; (f) SbF_5; (g) N_2O_5; (h) IF_7

D.7 (a) sulfur hexafluoride; (b) dinitrogen pentoxide; (c) nitrogen triiodide; (d) xenon tetrafluoride; (e) arsenic tribromide; (f) chlorine dioxide

D.9 (a) hydrochloric acid; (b) sulfuric acid; (c) nitric acid; (d) acetic acid; (e) sulfurous acid; (f) phosphoric acid

D.11 (a) ZnF_2; (b) $Ba(NO_3)_2$; (c) AgI; (d) Li_3N; (e) Cr_2S_3

D.13 (a) $BaCl_2$; (b) ionic

D.15 (a) sodium sulfite; (b) iron(III) oxide or ferric oxide; (c) iron(II) oxide or ferrous oxide; (d) magnesium hydroxide; (e) nickel(II) sulfate hexahydrate; (f) phosphorus pentachloride; (g) chromium(III) dihydrogen phosphate; (h) diarsenic trioxide; (i) ruthenium(II) chloride

D.17 (a) $CuCO_3$, copper (II) carbonate; (b) K_2SO_3, potassium sulfite; (c) LiCl, lithium chloride

D.19 (a) heptane; (b) propane; (c) pentane; (d) butane

D.21 (a) cobalt(III) oxide monohydrate, $Co_2O_3{\cdot}H_2O$; (b) cobalt(II) hydroxide, $Co(OH)_2$

D.23 E = Si; SiH_4, silicon tetrahydride; Na_4Si, sodium silicide

D.25 (a) lithium aluminum hydride, ionic (with a molecular anion); (b) sodium hydride, ionic

D.27 (a) selenic acid; (b) sodium arsenate; (c) calcium tellurite; (d) barium arsenate; (e) antimonic acid; (f) nickel(III) selenate

D.29 (a) alcohol; (b) carboxylic acid; (c) haloalkane

E.1 8.67×10^{10} km

E.3 18 Ca atoms

E.5 (a) 1.0×10^{-14} mol; (b) 3.2×10^6 years

E.7 (a) 1.38×10^{23} O atoms; (b) 1.26×10^{22} formula units; (c) 0.146 mol of H_2O

E.9 (a) 6.94 $g{\cdot}mol^{-1}$; (b) 6.96 $g{\cdot}mol^{-1}$

E.11 % ^{10}B = 73.8%; % ^{10}B = 26.2%

E.13 (a) 75 g of indium. (b) 15.0 g of P. (c) Neither, they have the same number of moles.

E.15 (a) 20.027 $g{\cdot}mol^{-1}$. (b) 1.11 $g{\cdot}cm^{-3}$. (c) volume of the spherical tank 905 m^3; volume calculated from the density data 901 m^3. (d) no. (e) The assumption in part (b) is reasonable because the nuclei are so small and the volume difference between a D_2O molecule and a H_2O can be ignored.

E.17 (a) 0.0981 mol, 5.91×10^{22} molecules; (b) 1.30×10^{-3} mol, 7.83×10^{20} molecules; (c) 4.56×10^{-5} mol, 2.79×10^{19} molecules; (d) 6.94 mol, 4.18×10^{24} molecules; (e) 0.312 mol N atoms, 1.88×10^{23} N atoms; 0.156 mol N_2, 9.39×10^{22} N_2 molecules

E.19 (a) 0.0134 mol; (b) 8.74×10^{-3} mol; (c) 430. mol; (d) 0.0699 mol

E.21 (a) 4.52×10^{23} formula units; (b) 124 mg; (c) 3.036×10^{22} formula units

E.23 (a) 2.992×10^{-23} $g{\cdot}molecule^{-1}$; (b) 3.34×10^{25} molecules

E.25 (a) 0.0417 mol; (b) 0.0834 mol; (c) 1.00×10^{23} molecules; (d) 0.3099

E.27 (a) \$109.28 per L H_2O; (b) \$70.20

E.29 (a) 12.013 $g{\cdot}mol^{-1}$; (b) 197.18 $g{\cdot}mol^{-1}$

E.31 3.18 mol

E.33 0.39%

F.1 78.90% C, 10.59% H, 10.51% O

F.3 52.15% C, 9.3787% H, 8.691% N, 29.78% O

F.5 (a) 63.4 $g{\cdot}mol^{-1}$; (b) copper(I) oxide

F.7 (a) Na_3AlF_6; (b) $KClO_3$; (c) NH_6PO_4 or $[NH_4][H_2PO_4]$

F.9 (a) PCl_5; (b) phosphorus pentachloride

F.11 $C_{16}H_{13}ClN_2O$

F.13 (a) OsC_4O_4; (b) $Os_3C_{12}O_{12}$

F.15 $C_8H_{10}N_4O_2$

F.17 $C_{49}H_{78}N_6O_{12}$
F.19 ethene (85.63%) > heptane (83.91%) > propanol (59.96%)
F.21 (a) empirical formula: C_2H_3Cl, molecular formula: $C_4H_6Cl_2$; (b) empirical formula: CH_4N, molecular formula: $C_2H_8N_2$
F.23 45.1%
G.1 (a) false. They can only be separated by chemical methods. (b) true. (c) false. The properties of a compound are unlike those of the elements that compose it.
G.3 (a) heterogeneous, decanting; (b) heterogeneous, dissolving followed by filtration and distillation; (c) homogeneous, distillation
G.5 Measure 482.2 g H_2O on a balance and pour it into a beaker. Then weigh 27.8 g of K_2NO_3 and mix it with the water until it totally dissolves.
G.7 15.2 g
G.9 (a) 13.5 mL; (b) 62.5 mL; (c) 5.92 mL
G.11 (a) Weigh 1.6 g (0.010 mol, molar mass of $KMnO_4$ = 158.04 $g{\cdot}mol^{-1}$) into a 1.0-L volumetric flask and add water to give a total volume of 1.0 L. Smaller (or larger) volumes could also be prepared by using a proportionally smaller (or larger) mass of $KMnO_4$.
(b) Starting with 0.050 $mol{\cdot}L^{-1}$ $KMnO_4$, add four volumes of water to one volume of starting solution, because the concentration desired is one-fifth of that of the starting solution. This relation can be derived from the expression $V_i \times \text{molarity}_i = V_f \times \text{molarity}_f$ where i represents the initial solution and f the final solution. For example, to prepare 50 mL of solution, you would add 40 mL of water to 10 mL of 0.050 $mol{\cdot}L^{-1}$ $KMnO_4$.
G.13 (a) 4.51 mL. (b) Add 48.0 mL of water to 12.0 mL of 2.5 $mol{\cdot}L^{-1}$ NaOH.
G.15 (a) 8.0 g; (b) 12. g
G.17 (a) 4.58×10^{-2} $g{\cdot}mol^{-1}$; (b) 9.07×10^{-3} $g{\cdot}mol^{-1}$
G.19 (a) 21.8 g; (b) 0.24 g; (c) 60 g
G.21 0.13 M Cl^- (aq)
G.23 Less than one molecule will be left after 69 doublings; no health benefits.
G.25 600. mL
G.27 The level that the instrument can detect: 2.07 ppb < 10 ppb. The instrument can detect levels lower than 10 ppb. It is satisfactory.
H.1 (a) You cannot add a different compound or element to the chemical equation which is not produced (or involved) in the chemical reaction. In this case, an O atom is not produced by the defined reaction. (b) $2\,Cu + SO_2 \longrightarrow 2\,CuO + S$
H.3 $2\,SiH_4 + 4\,H_2O \longrightarrow 2\,SiO_2 + 8\,H_2$
H.5 (a) $NaBH_4(s) + 2\,H_2O(l) \longrightarrow NaBO_2(aq) + 4\,H_2(g)$
(b) $Mg(N_3)_2(s) + 2\,H_2O(l) \longrightarrow Mg(OH)_2(aq) + 2\,HN_3(aq)$
(c) $2\,NaCl(aq) + SO_3(g) + H_2O(l) \longrightarrow Na_2SO_4(aq) + 2\,HCl(aq)$
(d) $4\,Fe_2P(s) + 18\,S(s) \longrightarrow P_4S_{10}(s) + 8\,FeS(s)$
H.7 (a) $Ca(s) + 2\,H_2O(l) \longrightarrow H_2(g) + Ca(OH)_2(aq)$
(b) $Na_2O(s) + H_2O(l) \longrightarrow 2\,NaOH(aq)$
(c) $3\,Mg(s) + N_2(g) \longrightarrow Mg_3N_2(s)$
(d) $4\,NH_3(g) + 7\,O_2(g) \longrightarrow 6\,H_2O(g) + 4\,NO_2(g)$
H.9 (I) $3\,Fe_2O_3(s) + CO(g) \longrightarrow 2\,Fe_3O_4(s) + CO_2(g)$
(II) $Fe_3O_4(s) + 4\,CO(g) \longrightarrow 3\,Fe(s) + 4\,CO_2(g)$
H.11 (I) $N_2(g) + O_2(g) \longrightarrow 2\,NO(g)$
(II) $2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g)$
H.13 $4\,HF(aq) + SiO_2(s) \longrightarrow SiF_4(aq) + 2\,H_2O(l)$
H.15 $C_7H_{16}(l) + 11\,O_2(g) \longrightarrow 7\,CO_2(g) + 8\,H_2O(g)$
H.17 $C_{14}H_{18}N_2O_5(s) + 16\,O_2(g) \longrightarrow 14\,CO_2(g) + 9\,H_2O(l) + N_2(g)$
H.19 $2\,C_{10}H_{15}N(s) + 26\,O_2(g) \longrightarrow 19\,CO_2(g) + 13\,H_2O(l) + CH_4N_2O(aq)$
H.21 (I) $H_2S(g) + 2\,NaOH(s) \longrightarrow Na_2S(aq) + 2\,H_2O(l)$
(II) $4\,H_2S(g) + Na_2S(alc) \longrightarrow Na_2S_5(alc) + 4\,H_2(g)$
(III) $2\,Na_2S_5(alc) + 9\,O_2(g) + 10\,H_2O(l) \longrightarrow 2Na_2S_2O_3{\cdot}5H_2O(s) + 6\,SO_2(g)$
H.23 (a) P_2O_5, P_2O_3; (b) P_4O_{10} (phosphorus(V) oxide); P_4O_6 (phosphorus(III) oxide); (c) $P_4(s) + 3\,O_2(g) \longrightarrow P_4O_6(s)$; $P_4(s) + 5\,O_2(g) \longrightarrow P_4O_{10}(s)$

I.1 The picture would show a precipitate, $CaSO_4(s)$, at the bottom of the flask composed of red and pink particles in a 1:1 ratio. Sodium (black) and chloride (blue) ions, NaCl(aq), would remain throughout the solution.
I.3 (a) dilute H_2SO_4, $Pb^{2+}(aq) + SO_4^{2-}(aq) \longrightarrow PbSO_4(s)$
(b) H_2S solution, $Mg^{2+}(aq) + S^{2-}(aq) \longrightarrow MgS(s)$
I.5 (a) nonelectrolyte; (b) strong electrolyte; (c) strong electrolyte
I.7 (a) soluble; (b) slightly soluble; (c) insoluble; (d) insoluble
I.9 (a) $Na^+(aq)$ and $I^-(aq)$;
(b) $Ag^+(aq)$ and $CO_3^{2-}(aq)$, Ag_2CO_3 is insoluble;
(c) $NH_4^+(aq)$ and $PO_4^{3-}(aq)$; (d) $Fe^{2+}(aq)$ and $SO_4^{2-}(aq)$
I.11 (a) $Fe(OH)_3$, precipitate; (b) Ag_2CO_3, precipitate forms; (c) no precipitate
I.13 (a) $Fe^{2+}(aq) + S^{2-}(aq) \longrightarrow FeS(s)$; Na^+, Cl^-

1.65 (a) $$V(r) = \left(\frac{-3e^2}{4\pi\boldsymbol{\varepsilon}_0}\right)\left(\frac{1}{r_2} + \frac{1}{r_2} + \frac{1}{r_3}\right) + \frac{e^2}{4\pi\boldsymbol{\varepsilon}_0}\left(\frac{1}{r_{12}} + \frac{1}{r_{13}} + \frac{1}{r_{23}}\right)$$
(b) The first term represents the coulombic attractions between the nucleus and each electron, and the second term represents the coulombic repulsions between each pair of electrons.

1.67 (a) false. Z_{eff} is considerably affected by the total number of electrons present in the atom because the electrons in the lower energy orbitals will "shield" the electrons in the higher energy orbitals from the nucleus. This effect arises because the e–e repulsions tend to offset the attraction of the electron to the nucleus. (b) true. (c) false. The electrons are increasingly less able to penetrate to the nucleus as l increases. (d) true

1.69 (a) excited state; (b) excited state; (c) excited state; (d) ground state

1.87 (a) silicon > sulfur > chlorine; (b) titanium > chromium > cobalt; (c) mercury > cadmium > zinc; (d) bismuth > antimony > phosphorus

1.89 $P^{3-} > S^{2-} > Cl^-$

1.91 (a) Ca; (b) Na; (c) Na

1.93 (a) Oxygen > selenium > tellurium; ionization energies generally decrease as one goes down a group. (b) Gold > osmium > tantalum; ionization energies generally decrease as one goes from right to left in the periodic table. (c) Lead > barium > cesium; ionization energies generally decrease as one goes from right to left in the periodic table.

1.95 (a) fluorine; (b) carbon; (c) chlorine; (d) lithium

1.97 (a) The inert-pair effect is the term used to describe the fact that heavy (Period 5 and greater) p-block elements have a tendency to form ions that are two units lower in charge than that expected based on their group number. (b) The inert-pair effect is presumed to be observed only for heavy elements because of the poor shielding ability of the d-electrons in these elements, enhancing the ability of the s-electrons to penetrate to the nucleus and therefore be bound tighter than expected.

1.99 (a) A diagonal relationship is a similarity in chemical properties between an element in the periodic table and one lying one period lower and one group to the right. (b) It is caused by the similarity in size of the ions. The lower-right element in the pair would generally be larger because it lies in a higher period, but it also will have a higher oxidation

state, which will cause the ion to be smaller. (c) For example, Al^{3+} and Ge^{4+} compounds show the diagonal relationship, as do Li^+ and Mg^{2+}.

1.101 (b) Li and Mg

1.103 The ionization energies of the s-block metals are considerably lower, thus making it easier for them to lose electrons in chemical reactions.

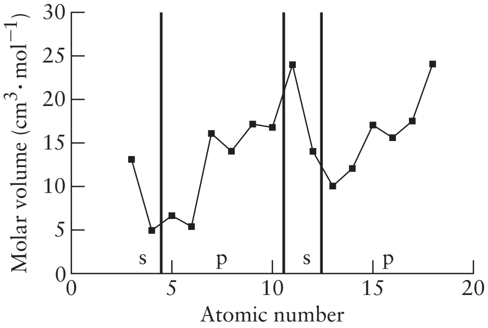
1.105 (a) metal; (b) nonmetal; (c) metal; (d) metalloid; (e) metalloid; (f) metal

1.107 (a) The observed values (7.30 MJ·mol^{-1} and 0.52 MJ·mol^{-1}) correspond respectively to the second (7300 kJ·mol^{-1}) and first (519 kJ·mol^{-1}) ionization energies of Li ($1s^2\,2s^1$). (b) The PES values observed (1.6 MJ·mol^{-1} and 0.90 MJ·mol^{-1}) correspond respectively to the second (1760 kJ·mol^{-1}) and first (900 kJ·mol^{-1}) ionization energies of Be ($1s^2\,2s^2$).

1.109 (a) 1.1×10^{14} s^{-1}; (b) 7.2×10^{-20} J; (c) 43 kJ·mol^{-1}

1.111 A ground-state oxygen atom has four electrons in the p-orbitals. This configuration means that as one goes across the periodic table in Period 2, oxygen is the first element encountered in which the p-electrons must be paired. This added electron–electron repulsion energy causes the ionization energy to be lower.

1.113



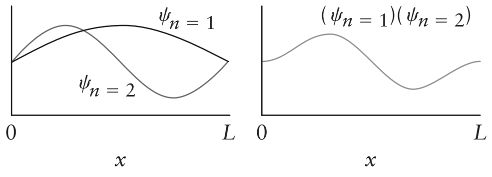
The molar volume roughly parallels atomic size (volume), which decreases as the s-subshell begins to fill and subsequently increases as the p-subshell fills (refer to the text discussion of periodic variation of atomic radii). In the above plot, this effect is most clearly seen in passing from Ne(10) to Na(11) and Mg(12), then to Al(13) and Si(14). Ne has a filled 2p-subshell; the 3s-subshell fills with Na and Mg; and the 3p-subshell begins to fill with Al.

1.115 In general, as the principal quantum number increases, the energy spacing between orbitals becomes smaller. This trend indicates that it does not take very much change in electronic structure to cause the normal orbital energy pattern to rearrange.

1.117 (a) $$\int_0^L \left(\sin\frac{\pi\cdot x}{L}\right)\cdot\left(\sin\frac{2\pi\cdot x}{L}\right)dx =$$

$$\frac{L}{2\pi}\left(\sin\frac{\pi\cdot x}{L}\right) - \frac{L}{6\pi}\left(\sin\frac{3\pi\cdot x}{L}\right)\Bigg|_0^L = 0$$

(b) Below is a plot of the first two wavefunctions describing the one-dimensional particle-in-a-box and the product of these two wavefunctions. Notice that the area above zero in the product exactly cancels the area below zero, making the integral of the product zero. This happens whenever a wavefunction that is unaltered by a reflection through the center of the box (wavefunctions with odd n) is multiplied by a wavefunction that changes sign everywhere when reflected through the center of the box (wavefunctions with even n).



1.119 (a) no; (b) increase

1.121 (a) 9.35×10^{-18} J. (b) x-ray. (c) 9.35×10^{-24} J. (d) The individual energy levels get closer as the chain gets longer.

1.123 (a) In copper, it is energetically favorable for an electron to be promoted from the 4s-orbital to a 3d-orbital, giving a completely filled 3d-subshell. In the case of Cr, it is energetically favorable for an electron to be promoted from the 4s-orbital to a 3d-orbital to exactly $\frac{1}{2}$ fill the 3d-subshell. (b) From Appendix 2C, the other elements for which anomalous electron configurations exist are Nb, Mo, Ru, Rh, Pd, Ag, Pt, and Au. Of these, the explanation used for chromium and copper is valid for Mo, Pd, Ag, and Au. (c) Because the np-orbitals are so much lower in energy than the $(n + 1)$s-orbitals, no elements are known where the $(n + 1)$s-orbitals fill in preference to the np-orbitals.

1.125 The element must be either tin or hafnium.

1.127 (a) 285 pm; (b) 194 pm; (c) 356 kJ·mol^{-1}

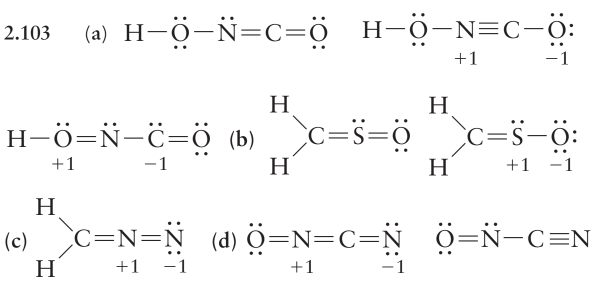
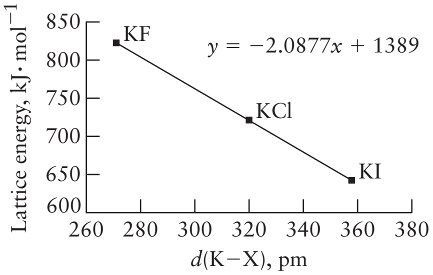
2.103



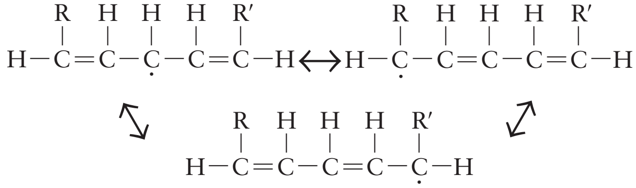
2.105

	d(K−X)	Lattice energy (kJ·mol^{-1})
fluoride	271 pm	826
chloride	319 pm	717
iodide	358 pm	645



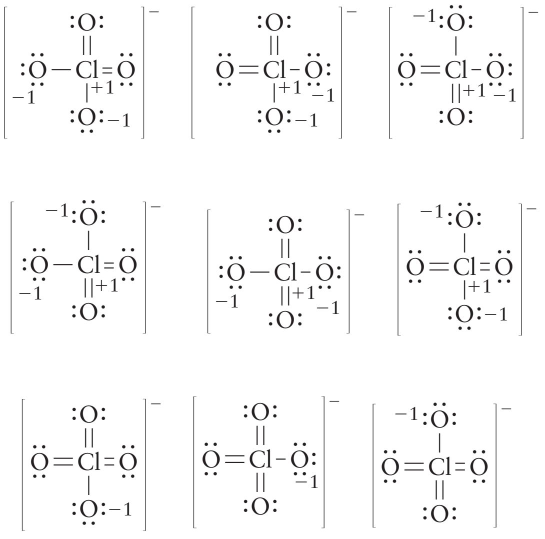
The data fit a straight line with a correlation coefficient of greater than 99%. (b) 693 kJ·mol^{-1}. (c) 689 kJ·mol^{-1}; the agreement is very good.

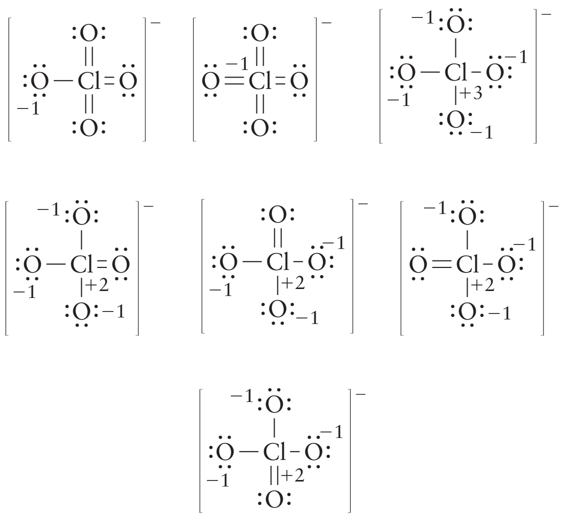
2.107



2.109 (a) I: Tl_2O_3; II: Tl_2O. (b) +3; +1. (c) [Xe]$4f^{14}5d^{10}$; [Xe]$4f^{14}5d^{10}6s^2$. (d) Because compound II has a lower melting point, it is probably more covalent, which is consistent with the fact that the +3 ion is more polarizing.

2.111 (a)

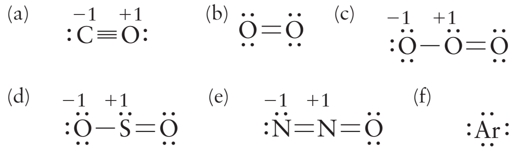




The four structures with three double bonds and the one with four double bonds are the most plausible Lewis structures according to formal charge arguments because these five structures minimize the formal charges. (b) The structure with four double bonds fits these observations best since its bond lengths would all be 140 pm, or only 4 pm shorter than the observed length. However, the four structures with three double bonds also fit because, if the double bonds are delocalized by resonance, we can estimate the average bond length to be $\frac{1}{4}$(170 pm) + $\frac{3}{4}$(140 pm) = 147.5 pm, or just 3.5 pm longer than observed. (c) +7. The structure with all single bonds fits this criterion best. (d) Approaches (a) and (b) are consistent but approach (c) is not. This result is reasonable because oxidation numbers are assigned by assuming ionic bonding.

2.113 The alkyne group has the stiffer C—H bond because a large force constant, *k*, results in a higher-frequency absorption.

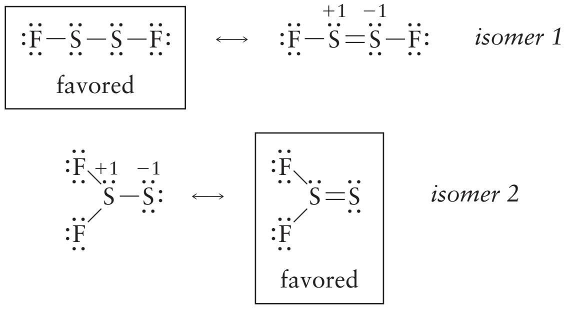
2.115 Look at the Lewis structures for the molecules:



Of these, (a), (c), (d), and (e) can all function as greenhouse gases.

2.117 (a) one; (b) ozone

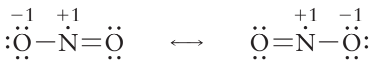
2.119 (a) They have some double bond character. (b) and (c) The Lewis structures for the two possible S_2F_2 are



If resonance is occurring, then one would expect that the S—S bond length is indeed between a single and a double bond in length.

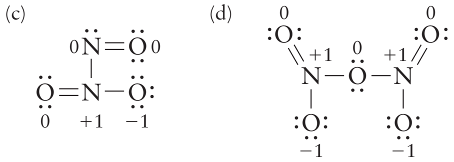
2.121 (a) The Lewis structures of NO and NO_2 are

(best possible structure)



(equivalent resonance structures)

From Table 2.4, the average bond dissociation energy of a N=O bond is 630 kJ·mol^{-1}, which is right in line with the Lewis structure of NO. The bond dissociation energy of each NO bond in NO_2 is 469 kJ·mol^{-1}, which is about half-way between an N—O double and an N—O single bond, suggesting that the resonance picture of NO_2 is a reasonable one. (b) An N—O single bond should have a bond length of 149 pm while an NO double bond should have a bond length of 120 pm (values are obtained by summing the respective covalent radii values from Figure 2.21). From Table 2.5 the length of a N—O triple bond can be estimated to be between 105 and 110 pm. Since NO itself has a bond length of 115 pm, this suggests that its actual bond order is somewhere between that of a double and a triple bond.



(e) $N_2O_5(g) + H_2O(l) \longrightarrow 2\ HNO_3(aq)$. Nitric acid is produced.
(f) 7.50×10^{-2} mol·L^{-1}. (g) NO: +2; NO_2: +4; N_2O_3: +3; N_2O_5: +5.

Chapter 3

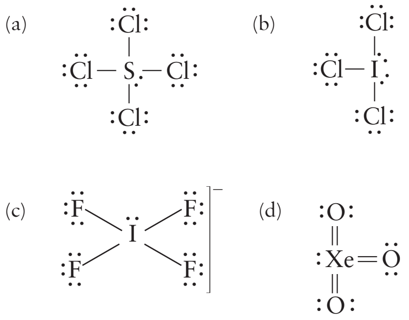
3.1 (a) must have lone pairs; (b) may have lone pairs

3.3 (a) angular; (b) slightly less than 120°

3.5 (a) trigonal pyramidal; (b) all O—S—Cl bond angles are equal; (c) slightly less than109.5°

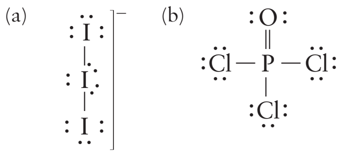
3.7 (a) linear; (b) slightly less than 180°

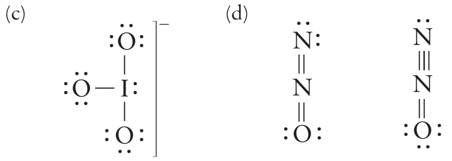
3.9



(a) seesaw AX_4E; (b) T-shaped AX_3E_2; (c) square planar AX_4E_2; (d) trigonal pyramidal AX_3E

3.11 The Lewis structures are





(resonance forms possible)

(a) linear, 180°, AX_2E_3 ; (b) tetrahedral, 109.5°, AX_4 ; (c) trigonal pyramid, less than 109.5°, AX_3E ; (d) linear, 180°, AX_2

3.13 The Lewis structures are

(a)  (b) 
(c)  (d) 
(a) tetrahedral; 109.5°, AX_4; (b) seesaw; 90° and 120°, AX_4E; (c) trigonal planar, 120°, AX_3; (d) trigonal pyramidal, 109.5°, AX_3E

3.15 (a) The angles represented by a and b are expected to be about 120°, while c is expected to be about 109.5° in 2, 4-pentanedione. All of the angles are expected to be about 120° in the acetylacetonate ion.
(b) The major difference arises at the C of the original sp^3 hybridized CH_2 group, which becomes sp^2 when it loses the hydrogen ion.

3.17 (a) slightly less than 120°; (b) 180°; (c) 180°; (d) slightly less than 109.5°

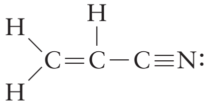
3.19 The Lewis structures are

(a)  (b) 
(c)  (d) 
Molecules (a) and (d) are polar; (b) and (c) are nonpolar.

3.21 (a) polar; (b) nonpolar; (c) polar

3.23 (a) 1 and 2; (b) 1

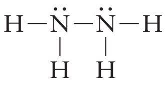
3.25



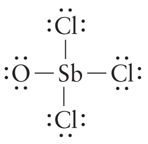
The first two carbons (CH_2 and CH) are sp^2 hybridized with H—C—H and C—C—H angles of 120°. The third carbon (bonded to N) is sp hybridized with a C—C—N angle of 180°.

3.27 (a) tetrahedral, 109.5°; (b) tetrahedral about the carbon atoms, 109.5°; C—Be—C angle of 180°; (c) angular, slightly less than 120°; (d) angular, slightly less than 120°

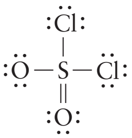
3.29 (a) H—C—H and H—C—C angles of 120° 
(b) linear, 180° Cl—C≡N:  (c) tetrahedral, 109.5° 
(d) The arrangement of atoms about each N is trigonal pyramidal 107°



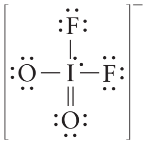
3.31 (a) tetrahedral:



(b) tetrahedral:



(c) seesaw:



3.33 (a) toward corners of a tetrahedron; (b) 180° apart; (c) toward the corners of an octahedron; (d) toward the corners of an equilateral triangle

3.35 (a) sp; (b) sp^2; (c) sp^3; (d) sp^3

3.37 (a) sp^2; (b) sp^3; (c) sp^3d; (d) sp^3

3.39 (a) sp^3; (b) sp^3d^2; (c) sp^3d; (d) sp^3

3.41 (a) sp^3; (b) nonpolar

3.43 increase

3.45 In formaldehyde, both the C and the O are sp^2 hybridized. The H—C—O bond angle is 120°; the molecule has three sigma bonds (one each connecting the two H's and O to the C) and one pi bond (between the C and the O).

3.47 Atomic orbitals a and b are mutually orthogonal if $\int a\cdot b\, d\tau = 0$ (assuming $a \neq b$) where the integration is over all space. Furthermore, an orbital, a, is normalized if $\int a^2\, d\tau = 1$. In this problem, the two hybrid orbitals are: $h_1 = s + p_x + p_y + p_z$ and $h_2 = s - p_x + p_y - p_z$. Therefore, to show these two orbitals are orthogonal we must show $\int h_1h_2\, d\tau = 0$.

$$\int h_1h_2\, d\tau = \int (s + p_x + p_y + p_z)(s - p_x + p_y - p_z)d\tau$$

$$= \int (s^2 - sp_x + sp_y - sp_z + sp_x - p_x{}^2 + p_xp_y - p_xp_z + sp_y - p_xp_y + p_y{}^2 - p_yp_z + sp_z - p_zp_x + p_zp_y - p_z{}^2)d\tau$$

Of course, this integral of a sum may be written as a sum of integrals:

$$\int s^2\, d\tau - \int sp_x d\tau + \int sp_y d\tau - \int sp_z\, d\tau + \cdots$$

Because the hydrogen wavefunctions are mutually orthogonal, the members of this sum which are integrals of a product of two different wavefunctions are zero. Therefore, this sum of integrals simplifies to

$$\int s^2 d\tau - \int p_x{}^2 d\tau + \int p_y{}^2 d\tau - \int p_z{}^2 d\tau = 1 - 1 + 1 - 1 = 0$$

3.49 $\lambda = 0.67\ sp^{0.67}$

3.51 (a) diamagnetic; (b) paramagnetic, one; (c) paramagnetic, one

3.53 (a) (1) $(\sigma_{2s})^2(\sigma_{2s}{}^*)^2(\sigma_{2p})^2\ (\pi_{2p_x})^2(\pi_{2p_y})^2(\pi_{2p_x}{}^*)^2(\pi_{2p_y}{}^*)^2(\sigma_{2p}{}^*)^1$

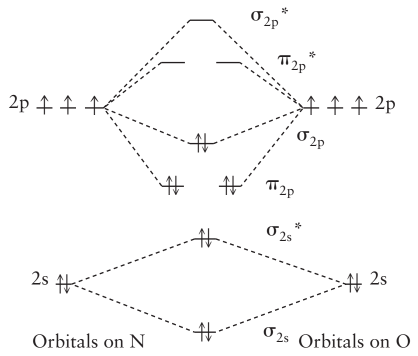
(2) $(\sigma_{2s})^2(\sigma_{2s}{}^*)^2(\sigma_{2p})^2\ (\pi_{2p_x})^2(\pi_{2p_y})^2\ (\pi_{2p_x}{}^*)^2(\pi_{2p_y}{}^*)^1$

(3) $(\sigma_{2s})^2(\sigma_{2s}{}^*)^2(\sigma_{2p})^2\ (\pi_{2p_x})^2(\pi_{2p_y})^2\ (\pi_{2p_x}{}^*)^2(\pi_{2p_y}{}^*)^2(\sigma_{2p}{}^*)^2$

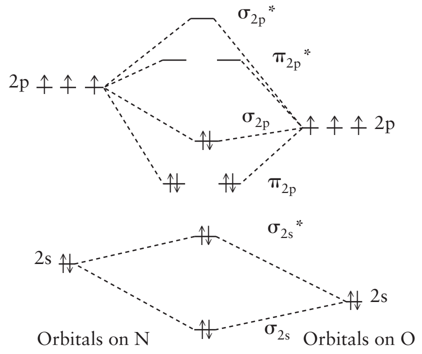
(b) (1) 0.5, (2) 1.5, (3) 0; (c) (1) and (2) are paramagnetic, with one unpaired electron each; (d) σ for (1) and (3), π for (2).

3.55 −2, 3

3.57 (a) The energy level diagram for N_2 is



(b) The oxygen atom is more electronegative, which will make its orbitals lower in energy than those of N. The revised energy-level diagram is shown below. This will make all of the bonding orbitals closer to O than to N in energy and will make all the antibonding orbitals closer to N than to O in energy. Energy level diagram for NO^+



(c) The electrons in the bonding orbitals will have a higher probability of being at O because O is more electronegative and its orbitals are lower in energy.

3.59 (a) $(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p_x})^1(\pi_{2p_y})^1$, 1; (b) $(\sigma_{2s})^2(\sigma_{2s}^*)^2$, 0;

(c) $(\sigma_{2s})^2(\sigma_{2s}^*)^2(\sigma_{2p})^2(\sigma_{2p_x})^2(\pi_{2p_y})^2(\pi_{2p_x}^*)^2(\pi_{2p_y}^*)^2$, 1

3.61 CO $(\sigma_{2s})^2(\sigma_{2s}^*)^2\ (\pi_{2p_x})^2(\pi_{2p_y})^2(\sigma_{2p})^2$; bond order = 3

$CO^+ (\sigma_{2s})^2(\sigma_{2s}^*)^2\ (\pi_{2p_x})^2(\pi_{2p_y})^2(\sigma_{2p})^1$; bond order = 2.5

Due to the higher bond order for CO, it should form a stronger bond and therefore have the higher bond enthalpy.

3.63 All are paramagnetic. B_2^- and B_2^+ have one unpaired electron whereas B_2 has two.

3.65 (a) F_2 has a bond order of 1; F_2^- has a bond order of $\frac{1}{2}$. (b) B_2 has a bond order of 1; B_2^+ has a bond order of $\frac{1}{2}$. B_2 will have the stronger bond.

3.67 C_2^-

3.69 Given the overlap integral $S = \int \psi_{A1s}\psi_{B1s}d\tau$, the bonding orbital $\psi = \psi_{A1s} + \psi_{B1s}$, and the fact that the individual atomic orbitals are normalized, we are asked to find the normalization constant N which will normalize the bonding orbital ψ such that:

$$\int N^2\psi^2 d\tau = N^2\int(\psi_{A1s} + \psi_{B1s})^2 d\tau = 1$$

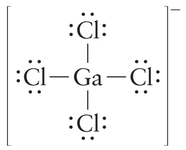
$$N^2\int(\psi_{A1s} + \psi_{B1s})^2 d\tau = N^2\int(\psi^2_{A1s} + 2\psi_{A1s}\psi_{B1s} + \psi^2_{B1s})d\tau$$

$$= N^2\left(\int\psi^2_{A1s}d\tau + 2\int\psi_{A1s}\psi_{B1s}d\tau + \int\psi^2_{B1s}d\tau\right)$$

Given the definition of the overlap integral above and the fact that the individual orbitals are normalized, this expression simplifies to $N^2(1 + 2S + 1) = 1$. Therefore,

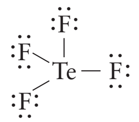
$$N = \sqrt{\frac{1}{2 + 2S}}$$

3.71 (a)



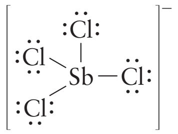
Shape: tetrahedral
Hybridization: sp^3
Bond angles: 109.5°
Nonpolar

(b)



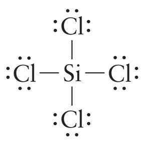
Shape: seesaw
Hybridization: dsp^3
Bond angles: > 90° and >120°
Polar

(c)



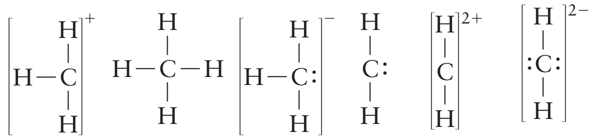
Shape: seesaw
Hybridization: dsp^3
Bond angles: > 90° and >120°
Polar

(d)



Shape: tetrahedral
Hybridization: sp^3
Bond angles: 109.5°
Nonpolar

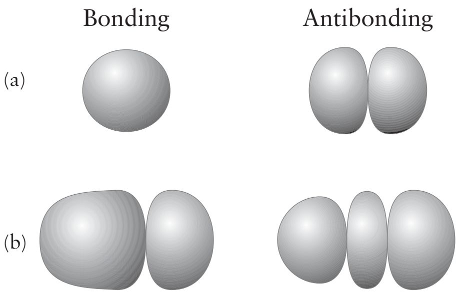
3.73 (a) The Lewis structures are



(b) None are radicals. (c) $CH_2^{2-} < CH_3^- < CH_4 < CH_2 < CH_3^+ < CH_2^{2+}$

3.75 (a) The elemental composition gives an empirical formula of CH_4O, which agrees with the molar mass. There is only one reasonable Lewis structure; this corresponds to the compound methanol. All of the bond angles about carbon should be 109.5°. The bond angles about oxygen should be close to 109.5° but will be somewhat less, due to the repulsions by the lone pairs. (b) Both carbon and oxygen are sp^3 hybridized. (c) The molecule is polar.

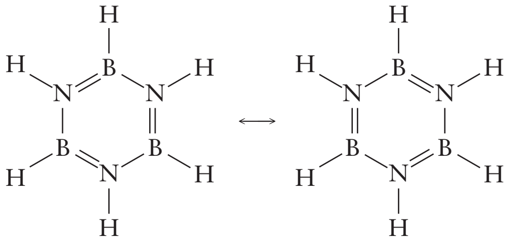
3.77



(c) The bonding and antibonding orbitals for HF appear different due to the fact that a p-orbital from the F atom is used to construct bonding and antibonding orbitals whereas in the H_2 molecule s-orbitals on each atom are used to construct bonding and antibonding orbitals.

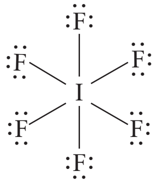
3.79 (a) $CF^+ < CF < CF^-$. (b) CF^+ has no unpaired electrons; CF has one unpaired electron and CF^- has two.

3.81 Orbitals at each B and N atom will be sp^2 hybridized.



3.83 The antibonding molecular orbital is obtained by taking the difference between two atomic orbitals that are proportional to e^{-r/a_0}. Halfway between the two nuclei, the distance from the first nucleus, r_1, is equal to the distance to the second nucleus, r_2, and the antibonding orbital is proportional to $\psi \propto e^{-r/a_0} - e^{-r/a_0} = 0$

3.85



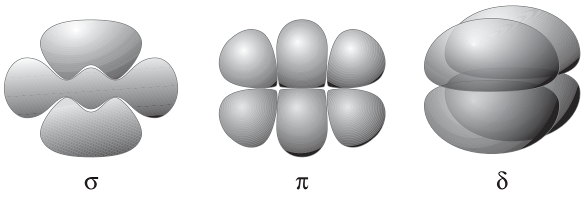
VSEPR Formula: AX_6
Shape: octahedral
Bond angles: all 90°

3.87
$$\Delta E = E_{LU} - E_{HO} = \frac{n_{LU}h^2}{8mN^2R^2} - \frac{n_{HO}h^2}{8mN^2R^2}$$
$$= \frac{h^2}{8mN^2R^2}\left[\left(\frac{N}{2}+1\right)^2 - \left(\frac{N}{2}\right)^2\right]$$
$$= \frac{h^2(N+1)}{8\,mN^2\,R^2}$$

To shift the wavelength of the absorption to longer wavelengths (lower energies) the length of the carbon chain, N, must increase.

3.89

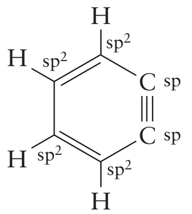
(a)



(b) σ > π > δ

3.91 (a) Net π-bond order will drop from three to two. (b) Net π-bond order will drop from three to two. Both are paramagnetic.

3.93 (a)

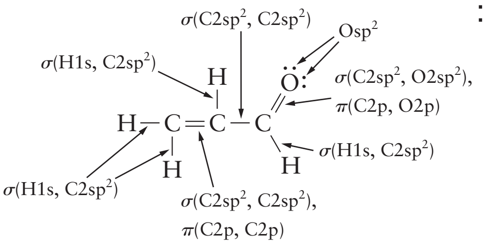


(b) Benzyne would be highly reactive because the two carbon atoms that are sp hybridized are constrained to have a very strained structure compared with the linear structure associated with their hybridization.

3.95 (a) The carbon atoms are all sp^3 hybridized. (b) The C—C—C, H—C—H, and H—C—C bond angles should be 109.5°. (c) Because of the ring structure, however, the C—C—C bond angles must be 60°. (d) The α-bond will have the electron density of the bond located on a line between the two atoms that it joins. (e) If the C atoms are truly sp^3 hybridized, then the bonding orbitals will not necessarily point directly between the C atoms. (f) The sp^3 hybridized orbitals can still overlap, even if they do not point directly between the atoms.

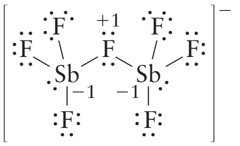
3.97 (a) and (d) have the possibility of n-to-π* transitions because these molecules possess both an atom with a lone pair of electrons and a π-bond to that atom.

3.99 (a–b)



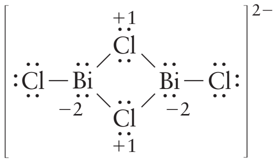
All atoms in this molecule have a formal charge of zero.

3.101 (a)

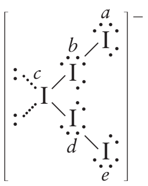


(b) sp^3d

3.103

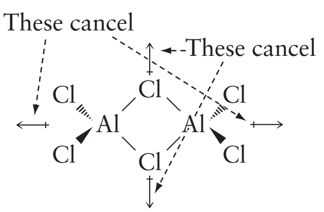


3.105



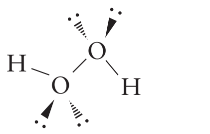
I_b and I_d are sp^3d hybridized with the attached atoms occupying axial positions, which results in a bond angle of 180° around each axial atom. I_c is sp^3 hybridized.

3.107 Al_2Cl_6 is nonpolar; all dipoles in the molecule (due to the Al—Cl bonds) will cancel:

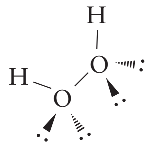


3.109 (a) sp^3d^3; (b) sp^3d^3f; (c) sp^2d

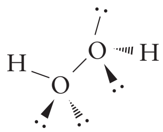
3.111 (a) The Lewis structure of hydrogen peroxide is H—Ö—Ö—H. No atoms have formal charges and the oxidation number of each O is −1. Oxidation number is more useful than formal charge in predicting the oxidizing ability of a compound as this will give us a clearer idea of whether a given atom wants to gain or lose an electron. (b) The bond angles should be about the same as those for water, about 104°. All atoms in this molecule are in the same plane, but because of unrestricted rotation around the O—O bond, it is expected that the hydrogens (and therefore the lone pairs of electrons on the oxygens) can rotate in and out of the plane; one of these rotations will lead to a polar structure (the different forms, arising from rotations around a single σ-bond, are called *rotomers*). Because of this, the molecule is expected to be polar, but slightly less so than water.



Planar, nonpolar rotomer



Planar, polar rotomer



Nonplanar, polar rotomer (one of many)

(c) (1) O_2: $(\sigma_{2s})^2(\sigma_{2s}{}^*)^2(\sigma_{2p})^2(\pi_{2p_x})^2(\pi_{2p_y})^2(\pi_{2p_x}{}^*)^1(\pi_{2p_y}{}^*)^1$; bond order = 2; paramagnetic.
(2) $O_2{}^-$: $(\sigma_{2s})^2(\sigma_{2s}{}^*)^2(\sigma_{2p})^2(\pi_{2p_x})^2(\pi_{2p_y})^2(\pi_{2p_x}{}^*)^2(\pi_{2p_y}{}^*)^1$; bond order = 1.5; paramagnetic.
(3) $O_2{}^+$: $(\sigma_{2s})^2(\sigma_{2s}{}^*)^2(\sigma_{2p})^2(\pi_{2p_x})^2(\pi_{2p_y})^2(\pi_{2p_x}{}^*)^1$; bond order = 2.5; paramagnetic.
(4) $O_2{}^{2-}$: $(\sigma_{2s})^2(\sigma_{2s}{}^*)^2(\sigma_{2p})^2(\pi_{2p_x})^2(\pi_{2p_y})^2(\pi_{2p_x}{}^*)^2(\pi_{2p_y}{}^*)^2$; bond order = 1; diamagnetic.
(d) Bond length should inversely follow bond order; therefore, the longest bond should belong to the molecule with the lowest bond order ($O_2{}^{2-}$) and the shortest bond should belong to the species with the largest bond order ($O_2{}^+$), which is borne out in the data given.
(e) $2\,Fe^{2+} + H_2O_2 + 2\,H^+ \longrightarrow 2\,Fe^{3+} + 2\,H_2O$, 1.21 g
(f) $2\,Fe^{3+} + H_2O_2 + 2\,OH^- \longrightarrow 2\,Fe^{2+} + 2\,H_2O + 2\,O_2$, 0.795 g

4.83 0.316

4.85 (a) The most probable speed is the one that corresponds to the maximum on the distribution curve. (b) The percentage decreases.

4.87 At low temperatures, this hydrogen bonding causes the molecules of HF to be attracted to each other more strongly, thus lowering the pressure. As the temperature is increased, the hydrogen bonds are broken and the pressure rises more quickly than for an ideal gas. Dimers (two HF molecules bonded to each other) and chaiins of HF molecules are known to form.

4.89 (a) Root mean square speed $v_{rms} = \sqrt{\frac{3RT}{M}}$; the smaller the molecular mass, the larger the v_{rms}. Therefore, H_2 molecules have greater root mean square speed. (b) NH_3 will have stronger attraction between molecules because the H atom on one NH_3 molecule tends to interact with the lone-pair electrons on the N of another NH_3 molecule (H-bonding).

4.91 (a) 1.62; (b) 38.9; (c) 1.88×10^3 atm. At low pressures, the ideal gas law gives essentially the same values as the van der Waals equation, but at high pressures there is a very significant difference.

4.93 17.58, CH_3CN; 3.392, CO_2; 2.253, CH_4; 0.2107, Ne

4.95 Clearly, the greater deviation from the ideal gas law values occurs at low volumes or higher pressures. Ammonia deviates more strongly and its van der Waals constants are larger than those for oxygen. This may likely arise because ammonia is polar and will have stronger intermolecular interactions.

$$= \frac{100v_{rms}^2 e^{-M100v_{rms}{}^{2}/2RT}}{v_{rms}^2 e^{-Mv_{rms}{}^{2}/2RT}} = 100e^{(-M100v_{rms}{}^{2}/2RT + Mv_{rms}{}^{2}/2RT)}$$

$$= 100e^{-99Mv^2{}_{rms}/2RT}$$

No, the distribution changes with temperature.
4.111 > 2.35 m
4.113 $254\ g\cdot mol^{-1}$; $x = 3.99$
4.115 23.1 g
4.117 (a) $V = 3.95 \times 10^7\ pm^3\cdot atom^{-1}$, $r = 211$ pm. (b) $r = 128$ pm; $V = 8.78 \times 10^6\ pm^3$. (c) The difference in these values illustrates that there is no easy definition for the boundaries of an atom. The van der Waals value obtained from the correction for molar volume is considerably larger than the atomic radius, owing perhaps to longer range and weak interactions between atoms. One should also bear in mind that the value for the van der Waals b is a parameter used to obtain a good fit to a curve, and its interpretation is more complicated than a simple molar volume.

5.9 (b) ≈ (c) < (e) < (a) < (d)
5.11 (d)
5.13 II because the dipoles are aligned with oppositely charged ends closest to each other thereby maximizing dipole–dipole attractions.
5.15 Ratio = 1.03, Al^{3+}
5.17 (a) Xenon is larger, with more electrons, giving rise to larger London forces that increase the melting point. (b) Hydrogen bonding in water causes the molecules to be held together more tightly than in diethyl ether. (c) Both molecules have the same molar mass, but pentane is a linear molecule compared to dimethylpropane, which is a compact, spherical molecule. The compactness of the dimethylpropane gives it a lower surface area. That means that the intermolecular attractive forces, which are of the same type (London forces) for both molecules, will have a larger effect for pentane.
5.19 $F = \frac{-dE_P}{dr} = \frac{-d}{dr}\left(\frac{1}{r^6}\right) = -\left(\frac{-6}{r^7}\right) \propto \frac{1}{r^7}$
5.21 (a) As intermolecular forces increase, boiling point will increase because more thermal energy is required to separate the molecules; (b) viscosity will increase with the increase of intermolecular forces because stronger intermolecular forces will make molecules less mobile (or will not let molecules move past one another easily); (c) surface tension also increases with the increase of intermolecular forces because stronger intermolecular forces tend to pull molecules together and inward.

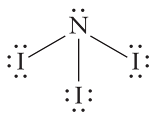
5.63 3.897 cm
5.65 There are too many ways that these molecules can rotate and twist so that they do not remain rodlike. The molecular backbone when the molecule is stretched out is rodlike, but the molecules tend to curl up

on themselves, destroying any possibility of long-range order with neighboring molecules. This is partly due to the fact that the molecules have only single bonds that allow rotation about the bonds, so that each molecule can adopt many configurations. If multiple bonds are present, the bonding is more rigid.

5.67 Use of a nonpolar solvent such as hexane or benzene in place of water should give rise to the formation of inverse micelles.

5.69 Because benzene is an isotropic solvent, its viscosity is the same in every direction. However, a liquid-crystal solvent is an anisotropic solvent and its viscosity is smaller in the direction parallel to the long axis of the molecule than in the "sideways" direction. Since methylbenzene is a small spherical molecule, its diffusion movement is not affected greatly whether the solvent is isotropic or anisotropic.

5.71 (a) trigonal pyramidal, polar, it can participate in dipole–dipole interactions



(b) trigonal planar, nonpolar, it cannot participate in dipole–dipole interactions

5.87 Fused silica, also known as fused quartz, is predominantly SiO_2 with very few impurities. This glass is the most refractory, which means that it can be used at the highest temperatures. Quartz vessels are routinely used for reactions that must be carried out at temperatures up to 1000°C. Vycor, which is 96% SiO_2, can be used at up to about 900°C, and normal borosilicate glasses at up to approximately 550°C. This is due to the fact that the glasses melt at lower temperatures as the amount of materials other than SiO_2 increases. The borosilicate glasses (Pyrex or Kimax) are commonly used because the lower softening points allow them to be more easily molded and shaped into different types of glass objects, such as reaction flasks, beakers, and other types of laboratory and technical glassware.

5.89 38.1 g

5.91 MA_2

5.93 35%

5.95 (a) 48%. (b) The percentage of empty space in an fcc unit cell is 26%.

5.97

H—F:···H—F:···H—F: ; the bond angle is about 180°

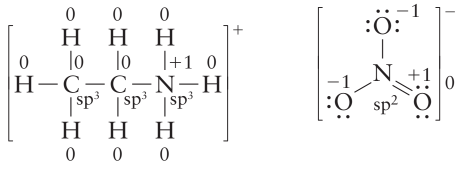
5.99 (a) Increase the electrical conductivity of graphite. (b) The angle of the x-ray beam will decrease.

5.101 The lattice layers from which constructive x-ray diffraction occurs are parallel. First draw perpendicular lines from the point of intersection of the top x-ray with the lattice plane to the lower x-ray for both the incident and diffracted rays. The x-rays are in phase and parallel at point A. If we want them to be still in phase and parallel when they exit the crystal, then they must still be in phase when they reach point C. In order for this to be true, the extra distance that the second beam travels with respect to the first must be equal to some integral number of wavelengths. The total extra distance traveled, A ⟶ B ⟶ C, is equal to $2x$. From the diagram, we can see that the angle A–D–B must also be equal to θ. The angles θ and α sum to 90°, as do the angles α and A–D–B. We can then write $\sin\theta = \dfrac{x}{d}$ and $x = d\sin\theta$. The total distance traveled is $2x = 2d\sin\theta$. So, for the two x-rays to be in phase as they exit the crystal, $2d\sin\theta$ must be equal to an integral number of wavelengths.

5.103 5.074

5.105 633 K

5.107 (a)–(b)



(c) The anion (NO_3^-). N^{5+} can be reduced to a lower oxidation state by a reducing agent. (d) $CH_3CH_2NH_2 + HNO_3 \longrightarrow CH_3CH_2NH_3^+\ NO_3^-$ (acid–base). (e) Theoretical yield = 0.0600 mol HNO_3; percentage yield = 63.2%. The forces holding EAN together in the solid contain ion–ion, hydrogen-bonding, and London forces. NaCl and NaBr have only ion–ion and London forces to hold them together (no hydrogen bonding involved). However, the ion–ion forces in NaCl and NaBr are much stronger that those in EAN because of the smaller ion sizes of NaCl and NaBr. As the ion size increases, the distance between ions will increase and the ion–ion forces will decrease, and the melting point will decrease.

Chapter 6

6.1 4.47×10^{-19} J

6.3 0.9703

6.5 The major impurity is carbon; it is removed by oxidation of carbon to CO_2, followed by capture of the CO_2 by base to form a slag.

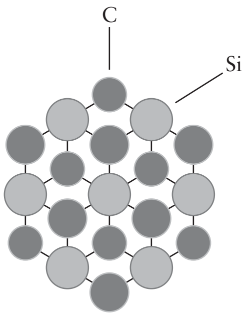
6.7 Alloys are usually (1) harder and more brittle, and (2) poorer conductors of electricity than the metals from which they are made.

6.9 (a) The alloy is undoubtedly interstitial because the atomic radius of nitrogen is much smaller (74 pm versus 124 pm) than that of iron. The rule of thumb is that the solute atom be less than 60% the solvent atom in radius in order for an interstitial alloy to form. That criterion is met here. (b) We expect that nitriding will make iron harder and stronger, with a lower electrical conductivity.

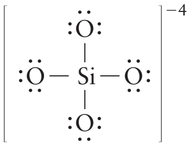
6.11 (a) 2.8 Cu per Ni; (b) 15 Sn:1.2 Sb:1 Cu

6.13 In diamond, carbon is sp^3 hybridized and forms a tetrahedral, three-dimensional network structure, which is extremely rigid. Graphite carbon is sp^2 hybridized and planar. Its application as a lubricant results from the fact that the two-dimensional sheets can "slide" across one another, thereby reducing friction. In graphite, the unhybridized p-electrons are free to move from one carbon atom to another, which results in its high electrical conductivity. In diamond, all electrons are localized in sp^3 hybridized C–C σ-bonds, so diamond is a poor conductor of electricity.

6.15 (a) 1.1×10^{16} C atoms; (b) 18 nmol
6.17 Due to the greater polarizing ability of the smaller Mg^{2+} ion on the carbonate ion, we expect $MgCO_3$ to be less stable than $CaCO_3$. Therefore, we expect that the oxide formed is MgO and that the carbonate is $CaCO_3$. Furthermore, for $MgCO_3(s) \longrightarrow MgO(s) + CO_2(g)$, $\Delta G_r°$ is roughly +50 kJ, and for $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$, $\Delta G_r°$ is roughly +130 kJ (as calculated from the data in Appendix 2A). Thus, the formation of MgO versus that of CaO is thermodynamically favored.
6.19 (a) The top layer of a unit cell of moissanite is



(b) Although a Si atom is heavier than a C atom, a Si atom is larger than a C atom. This will result in more empty spaces between C and Si atoms during the packing process, which makes moissanite less dense than diamond.
6.21 (a) hexagonal; (b) carbonate ions, 6; $CaCO_3$, 4
6.23 15.4 cm^3
6.25



Formal charge: Si = 0, O = −1; oxidation number: Si = +4, O = −2; this is an AX_4 VSEPR structure; therefore, the shape is tetrahedral.
6.27 (a) The $Si_2O_7^{6-}$ ion is built from two SiO_4^{4-} tetrahedral ions in which the silicate tetrahedra share one O atom. This is the only case in which one O is shared. (b) The pyroxenes, for example, jade, $NaAl(SiO_3)_2$, consist of chains of SiO_4 units in which two O atoms are shared by neighboring units. The repeating unit has the formula SiO_3^{2-}.
6.29 +4
6.31 930 g
6.33 Ionic fluorides react with water to liberate HF, which then reacts with the glass. Glass bottles used to store metal fluorides become brittle and may disintegrate upon standing on the shelf.
6.35 The iron ions impart a deep red color to the clay, which is not desirable for the manufacture of fine china; a white base is aesthetically more pleasing.
6.37 (a) +5; (b) +4
6.39 The conductivity of a semiconductor increases with temperature as increasing numbers of electrons are promoted into the conduction band, whereas the conductivity of a metal will decrease as the motion of atoms will slow down the migration of electrons.
6.41 0.27 Ω
6.43 $n = 1.8 \times 10^6$
6.45 (a) In and Ga; (b) P and Sb
6.47 $YBa_2Cu_3O_7$
6.49 In fluorescence, light absorbed by molecules is immediately emitted, whereas in phosphorescence, molecules remain in an excited state for a period of time before emitting the absorbed light. In both phenomena, the energy of the emitted photon is lower than that of the absorbed photon (emitted photons have a longer wavelength).
6.51 Fluorescent dyes allow much smaller concentrations of biomolecules to be detected than is normally possible.
6.53 Sc, V, Fe, Ni, Zr, Mo, Ru, Lu, Ta, Re, Ir, Au, Ti, Mn, Co, Y, Nb, Tc, Rh, Hf, W, Os, Pt
6.55 The compound is ferromagnetic below T_c because the magnetization is higher. Above the Curie temperature, the compound is a simple paramagnet with randomly oriented spins, but below that temperature, the spins align and the magnetization increases.
6.57 The "top down" approach to manufacturing nanomaterials refers to physically assembling the nanoparticles into the form factor desired; on the other hand, the "bottom up" approach utilizes specific intermolecular interactions to cause the nanomaterials to self-assemble.
6.59 yellow, 726.9 pm
6.61 290 $m \cdot s^{-1}$
6.63 $E_{111} = \dfrac{3h^2}{8m_eL^2}$; $E_{211} = \dfrac{3h^2}{4m_eL^2}$; $E_{221} = \dfrac{9h^2}{8m_eL^2}$. The 211, 121, and 112 levels are degenerate; that is $E_{211} = E_{121} = E_{112}$.
The 221, 122, and 212 levels are degenerate; that is $E_{221} = E_{121} = E_{212}$.
6.65 $SiC(s) + 2NaOH(l) + 2O_2(g) \longrightarrow Na_2SiO_3(s) + H_2O(g) + CO_2(g)$
6.67 (a) 3.75 g; (b) 6.89 Kg
6.69 When semiconductors are at very low temperatures, the valence band is fully occupied and the conduction band is empty, so the conductivity is low. As temperature increases in a vacuum, some electrons are promoted from the valence band to the conduction band and cause an increase in conductivity. However, when semiconductors are heated in oxygen, chemisorptions will occur and adsorbed oxygen on the surface will trap electrons, forming negative oxygen ions, which will decrease the electron conductivity.
6.71 Plot (a) was obtained from an organic dye and plot (b) was obtained from a quantum dot suspension. For an organic dye solution, since the sizes of organic dye molecules are the same and the quantum levels (n) are well fixed, a distinct absorption spectrum will be obtained. For a quantum dot suspension, due to the diameter variation of quantum dots and variable quantum transition levels, the separation of energy levels will vary (as $1/r^2$). Therefore, the wavelength of light that can cause excitation will also vary. In addition, since the sizes of quantum dots vary only slightly, a continuous absorption spectrum is normally observed.
6.73 (a) C: sp^2; B: sp^2; N: sp^2. (b) 10. (c) In C_{60} the carbon atoms are sp^2 hybridized and are nearly planar. However, the curvature of the molecule introduces some strain at the carbon atoms so that there is some tendency for some of the carbon atoms to undergo conversion to sp^3 hybridization. However, to make every carbon sp^3 hybridized would introduce much more strain on the carbon cage and, after a certain point, further addition of hydrogen becomes unfavorable. (d) The spherical structures require the formation of five-member rings. Boron nitride cannot form these rings because they would require high-energy boron–boron or nitrogen–nitrogen bonds.(e) 3.491 $g \cdot cm^{-3}$. (f) cubic

7.83 (a) +248 $kJ \cdot mol^{-1}$; (b) −45 $kJ \cdot mol^{-1}$; (c) −115 $kJ \cdot mol^{-1}$
7.85 approximately 228 kJ
7.87 (a) 33.93 $kJ \cdot mol^{-1}$. (b) 30.94 $kJ \cdot mol^{-1}$. (c) The value in the table is 30.8 $kJ \cdot mol^{-1}$ for the enthalpy of vaporization of benzene. Heat capacities are not strictly constant with temperature.
7.89 For the reaction: $A + 2B \longrightarrow 3C + D$ the molar enthalpy of reaction at temperature 2 is given by:

$$\Delta H_{r,2}° = H_{m,2}°(\text{products}) - H_{m,2}°(\text{reactants})$$
$$= 3H_{m,2}°(C) + H_{m,2}°(D) - H_{m,2}°(A) - 2H_{m,2}°(B)$$
$$= 3[H_{m,1}°(C) + C_{p,m}(C)(T_2 - T_1)] + [H_{m,1}°(D) + C_{p,m}(D)(T_2 - T_1)]$$
$$-[H_{m,1}°(A) + C_{p,m}(A)(T_2 - T_1)] - 2[H_{m,1}°(B) + C_{p,m}(B)(T_2 - T_1)]$$
$$= 3H_{m,1}°(C) + H_{m,1}°(D) - H_{m,1}°(A) - 2H_{m,1}°(B)$$
$$+ [3C_{p,m}(C) + C_{p,m}(D) - C_{p,m}(A) - 2C_{p,m}(B)](T_2 - T_1)$$
$$= \Delta H_{r,1}° + [3C_{p,m}(C) + C_{p,m}(D) - C_{p,m}(A) - 2C_{p,m}(B)](T_2 - T_1)$$

Finally, $\Delta H_{r,2}° = \Delta H_{r,1}° + \Delta C_p(T_2 - T_1)$, which is Kirchhoff's law.
7.91 132.0 kJ
7.93 (a) $2H_2S(g) + O_2(g) \rightarrow 2S(s) + 2H_2O(l)$, $\Delta H = -530.$ kJ; (b) -4.96×10^5 kJ; (c) cooled

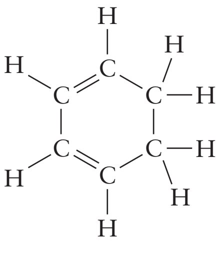
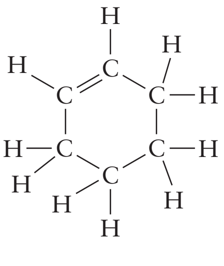
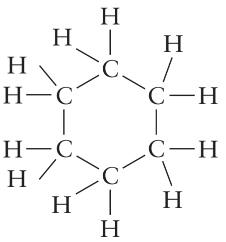
7.107 (a) (1)



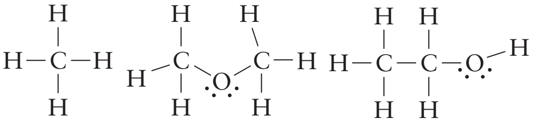
(2)



(3)



(b) −372 kJ. (c) −205.4 $kJ \cdot mol^{-1}$. (d) The hydrogenation of benzene is much less exothermic than predicted by bond enthalpy estimations. Part of this difference can be due to the inherent inaccuracy of using average values, but the difference is so large that this cannot be the complete explanation. As may be expected, the resonance energy of benzene makes it more stable than would be expected by treating it as a set of three isolated double and three isolated single bonds. The difference in these two values [−205 kJ − (−372 kJ) = 167 kJ] is a measure of how much more stable benzene is than the Kekulé structure would predict.
7.109 (a) 2326 $kJ \cdot mol^{-1}$. (b) 3547 kJ. (c) more stable. (d) 20 kJ per carbon atom. (e) 25 kJ per carbon atom. (f) There is slightly less stabilization per carbon atom in C_{60} than in benzene. This fits with expectations, as the C_{60} molecule is forced by its geometry to be curved.
7.111 From the combustion equations we can see that the differences are (1) the consumption of $\frac{18}{4}$ more moles of $O_2(g)$ and (2) the production of three more moles of $H_2O(l)$ for the combustion of aniline. Because the $\Delta H_f°$ of $O_2(g)$ is 0, the net difference will be the production of 3 more moles of $H_2O(l)$ or $3 \times (-285.83\ kJ \cdot mol^{-1}) = -857.49$ kJ.
7.113 (a) 1.5 L; (b) $SO_2(g)$; (c) 1.1 L; (d) 40 J, on the system; (e) −3.0 kJ, heat leaves the system; (f) −2960 J
7.115 (a)



(b) CH_4: −698 $kJ \cdot mol^{-1}$; CH_3OCH_3: −1070 $kJ \cdot mol^{-1}$; CH_3CH_2OH: −988 $kJ \cdot mol^{-1}$. The burning of 1 mole of dimethyl ether releases the most heat. (c) Methane as it releases the most heat per gram.
(d) 1.1×10^3 L. (e) methane gas, −890 $kJ \cdot mol^{-1}$ CO_2 (less CO_2); ethanol liquid, −684 $kJ \cdot mol^{-1}$ CO_2 (more CO_2); octane liquid, −684 $kJ \cdot mol^{-1}$ CO_2 (more CO_2)

Chapter 8

8.1 (a) 0.341 $J \cdot K^{-1} \cdot s^{-1}$. (b) 29.5 $kJ \cdot K^{-1} \cdot day^{-1}$. (c) Less, because in the equation $\Delta S = \dfrac{-\Delta H}{T}$; if T is larger ΔS is smaller.
8.3 (a) 0.22 $J \cdot K^{-1}$. (b) 0.17 $J \cdot K^{-1}$. (c) The entropy change is smaller at higher temperatures. The same amount of heat has a greater effect on entropy changes when transferred at lower temperatures.
8.5 (a) 6.80 $J \cdot K^{-1}$; (b) 4.08 $J \cdot K^{-1}$
8.7 14.8 $J \cdot K^{-1}$
8.9 42.4 $J \cdot K^{-1}$
8.11 −14.6 $J \cdot K^{-1}$
8.13 Assume the transfer of energy as heat is reversible. The change in entropy for each block (block 1 and block 2) is $\Delta S_1 = \dfrac{q_1}{T_1}$ and $\Delta S_2 = \dfrac{q_2}{T_2}$. If energy is transferred, then the change in entropy for the system is $\Delta S = \Delta S_1 + \Delta S_2 = \dfrac{q_1}{T_1} + \dfrac{q_2}{T_2}$. If 1 J of energy is transferred from block 2 to block 1, $q_1 = +1$ J, $q_2 = -1$ J, and $\Delta S = \dfrac{1}{T_1} - \dfrac{1}{T_2}$.
For the transfer of heat from block 2 to block 1 to be spontaneous, ΔS must be positive and, therefore, T_2 would have to be greater than T_1.
8.15 (a) Heat enters the house interior and the entropy of the house interior increases. Heat leaves the house exterior and the entropy of the house exterior decreases. (b) $\Delta S_{interior} < \Delta S_{exterior}$

8.17 (a) $-22.0\ J\cdot K^{-1}$; (b) $134\ J\cdot K^{-1}$

8.19 (a) 290 K. (b) 293.9 K. (c) good agreement. (d) Because the enthalpy and entropy of vaporization are slightly different from the values calculated at 298 K, but the boiling point of ethanal is not 298 K.

8.21 (a) 253 K. (b) 248 K, which is in reasonably close agreement. The value $85\ J\ K^{-1}\ mol^{-1}$ is an average value for the entropy of vaporization of organic liquids and therefore deviations are expected when using this average value for individual organic liquids.

8.23 (a) $30\ kJ\cdot mol^{-1}$; (b) $-11\ J\cdot K^{-1}$

8.25 COF_2; COF_2, and BF_3 are both trigonal planar molecules, but it would be possible for the molecule to be disordered with the fluorine and oxygen atoms occupying the same locations. Because all the groups attached to boron are identical, such disorder is not possible.

8.27 $14.9\ J\cdot K^{-1}$

8.29 (a) HBr(g); (b) NH_3(g); (c) I_2 (l); (d) 1.0 mol Ar(g) at 1.00 atm

8.31 C(s, diamond) $<$ H_2O(s) $<$ H_2O(l) $<$ H_2O(g). It is easy to order H_2O in its various phases because entropy will increase when going from a solid to a liquid to a gas. The main question concerns where to place C(s, diamond) in this order, and that will essentially become a question of whether C(s, diamond) should have more or less entropy than H_2O(s), because we would automatically expect C(s, diamond) to have less entropy than any liquid. Water is a molecular substance held together in the solid phase by weak hydrogen bonds, and in C(s, diamond) the carbon is more rigidly held in place and will have less entropy.

8.33 (a) Iodine is expected to have higher entropy due to its larger mass and consequently a larger number of fundamental particles. (b) When we consider the two structures, it is clear that 1-pentene will have more flexibility in its framework than cyclopentane, which will be comparatively rigid. Therefore, we predict 1-pentene to have a higher entropy. (c) Ethene (or ethylene) is a gas and polyethylene is a solid, so we automatically expect ethene to have a higher entropy. Also, for the same mass, a sample of ethene will be composed of many small molecules, whereas polyethylene will be made up of fewer but larger molecules.

8.35 (a) decrease; (b) increase; (c) decrease

8.37 $\Delta S_B < \Delta S_C < \Delta S_A$. The change in entropy for container A is greater than that for container B or C due to the greater number of particles. The change in entropy in container C is greater than that of container B because of the disorder due to the vibrational motion of the molecules in container C.

8.39 (a) $-163.34\ J\cdot K^{-1}\cdot mol^{-1}$; the entropy change is negative because 1 mol of a liquid is formed from 1.5 mol of gas. (b) $-86.5\ J\cdot K^{-1}\cdot mol^{-1}$; the entropy change is negative because the number of moles of gas has decreased by 0.5. (c) $160.6\ J\cdot K^{-1}\cdot mol^{-1}$; the entropy change is positive because the number of moles of gas has increased by 1. (d) $-36.8\ J\cdot K^{-1}\cdot mol^{-1}$; the four moles of solid products are more ordered than the four moles of solid reactants.

8.41 $dS = \dfrac{dq_{rev}}{T} = \dfrac{C_{P,m}dT}{T}$ and, therefore, $\Delta S = \displaystyle\int_{T_1}^{T_2} \frac{C_{P,m}}{T}\,dT$.

If $C_{P,m} = a + bT + c/T^2$, then

$$\Delta S = \int_{T_1}^{T_2} \frac{a + bT + c/T^2}{T}\,dT$$

$$= \int_{T_1}^{T_2}\left(\frac{a}{T} + b + \frac{c}{T^3}\right)dT = \left(a\ln(T) + bT - \frac{c}{2T^2}\right)\Bigg|_{T_1}^{T_2}$$

$$= a\ln\left(\frac{T_2}{T_1}\right) + b(T_2 - T_1) - \frac{c}{2}\left(\frac{1}{T_2^2} - \frac{1}{T_1^2}\right)$$

ΔS(true) for heating graphite from 298 K to 400 K is

$$= (16.86\ J\cdot K^{-1}\cdot mol^{-1})\ln\left(\frac{400\ K}{298\ K}\right) +$$

$$+ (0.00477\ J\cdot K^{-2}\cdot mol^{-1})(400\ K - 298\ K)$$

$$- \frac{(-8.54 \times 10^5\ J\cdot K\cdot mol^{-1})}{2}\left(\frac{1}{(400\ K)^2} - \frac{1}{(298\ K)^2}\right)$$

$$= 3.31\ J\cdot K^{-1}\cdot mol^{-1}$$

If we assume a constant heat capacity at the mean temperature of 350 K,

$$C_{P,m} = (16.86\ J\cdot K^{-1}\cdot mol^{-1}) + (0.00477\ J\cdot K^{-2}\cdot mol^{-1})(350\ K) + \frac{(-8.54 \times 10^5\ J\cdot K\cdot mol^{-1})}{(350\ K)^2} = 11.6\ J\cdot K^{-1}\cdot mol^{-1}$$

and

$$\Delta S(\text{mean}) = C_{P,m}\ln\frac{T_2}{T_1} = (11.6\ J\cdot K^{-1}\cdot mol^{-1})\ln\left(\frac{400\ K}{298\ K}\right) = 3.41\ J\cdot K^{-1}\cdot mol^{-1}$$

Not integrating the heat capacity leads to roughly a 3.0% error in ΔS.

8.43 $111\ J\cdot K^{-1}\cdot mol^{-1}$

8.45 $\Delta S_c = 11.9\ J\cdot K^{-1}$, $\Delta S_h = 11.1\ J\cdot K^{-1}$, $\Delta S_{tot} = 0.8\ J\cdot K^{-1}$

8.47 (a) $\Delta S_{surr} = -73\ J\cdot K^{-1}$, $\Delta S_{system} = 73\ J\cdot K^{-1}$; (b) $\Delta S_{surr} = -29.0\ J\cdot K^{-1}$, $\Delta S_{system} = 29.0\ J\cdot K^{-1}$; (c) $\Delta S_{surr} = -29.0\ J\cdot K^{-1}$, $\Delta S_{system} = 29.0\ J\cdot K^{-1}$

8.49 (a) $\Delta S_{tot} = 0$, so $\Delta S_{surr} = -\Delta S = -3.84\ J\cdot K^{-1}$; (b) $\Delta S = +3.84\ J\cdot K^{-1}$, $\Delta S_{surr} = 0$, $\Delta S_{tot} = +3.84\ J\cdot K^{-1}$.

8.51 Spontaneous change means $\Delta S_{tot} > 0$. A vapor to liquid change is condensation and it releases heat. However, as shown in the diagram, the temperature of the system does not change. Therefore the released heat must have left the system to the surroundings. Since heat flows from hot to cold, the temperature of the surroundings (T_{surr}) must be lower than the temperature of the system (T_{sys}), and since $\Delta S_{sys} = \dfrac{q_{rev}}{T_{sys}}$ and $\Delta S_{surr} = \dfrac{q_{rev}}{T_{surr}}$, then $\Delta S_{tot} > 0$.

8.53 Exothermic reactions tend to be spontaneous because the result is an increase in the entropy of the surroundings. Using the mathematical relationship $\Delta G_r = \Delta H_r - T\Delta S_r$, it is clear that if ΔH_r is large and negative compared to ΔS_r, then the reaction will generally be spontaneous.

8.55 (a) $\Delta H_r° = -235.8\ kJ\cdot mol^{-1}$, $\Delta S_r° = -133.17\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = -195.8\ kJ\cdot mol^{-1}$; (b) $\Delta H_r° = 11.5\ kJ\cdot mol^{-1}$, $\Delta S_r° = -149.7\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = 56.2\ kJ\cdot mol^{-1}$; (c) $\Delta H_r° = -57.20\ kJ\cdot mol^{-1}$, $\Delta S_r° = -175.83\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = -4.73\ kJ\cdot mol^{-1}$

8.57 (a) $\frac{1}{2} N_2(g) + \frac{3}{2} H_2(g) \longrightarrow NH_3(g)$; $\Delta H_r° = -46.11\ kJ\cdot mol^{-1}$, $\Delta S_r° = -99.38\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = -16.49\ kJ\cdot mol^{-1}$
(b) $H_2(g) + \frac{1}{2} O_2(g) \longrightarrow H_2O(g)$; $\Delta H_r° = -241.82\ kJ\cdot mol^{-1}$, $\Delta S_r° = -44.42\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = -228.58\ kJ\cdot mol^{-1}$
(c) C(s, graphite) $+ \frac{1}{2} O_2(g) \longrightarrow CO(g)$; $\Delta H_r° = -110.53\ kJ\cdot mol^{-1}$, $\Delta S_r° = 89.36\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = -137.2\ kJ\cdot mol^{-1}$
(d) $\frac{1}{2} N_2(g) + O_2(g) \longrightarrow NO_2(g)$; $\Delta H_r° = 33.18\ kJ\cdot mol^{-1}$, $\Delta S_r° = -60.89\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = 51.33\ kJ\cdot mol^{-1}$

8.59 (a) $-141.74\ kJ\cdot mol^{-1}$, spontaneous; (b) $130.4\ kJ\cdot mol^{-1}$, not spontaneous; (c) $-10590.9\ kJ\cdot mol^{-1}$, spontaneous

8.61 (a) and (d) are stable.

8.63 (a) PCl_5(g)

8.65 (a) $\Delta H_r° = -196.10\ kJ\cdot mol^{-1}$, $\Delta S_r° = 125.8\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = -233.56\ kJ\cdot mol^{-1}$; (b) $\Delta H_r° = -748.66\ kJ\cdot mol^{-1}$, $\Delta S_r° = 14.6\ J\cdot K^{-1}\cdot mol^{-1}$, $\Delta G_r° = -713.02\ kJ\cdot mol^{-1}$

8.67 (a) $\Delta G_r° = -98.42\ kJ\cdot mol^{-1}$, spontaneous below 612.9 K; (b) $\Delta G_r° = -283.7\ kJ\cdot mol^{-1}$, spontaneous at all temperatures; (c) $\Delta G_r° = 3.082\ kJ\cdot mol^{-1}$, nonspontaneous at all temperatures

8.69 Reaction A is spontaneous, but reaction B is not spontaneous at any temperature.

8.71 21.6 mol

8.73 (a) 1 = 1-propanol; (b) no

8.75 (a) $\Delta G° < 0$; (b) $\Delta H°$, unable to tell; (c) $\Delta S°$, unable to tell; (d) $\Delta S_{totalr} > 0$

8.77 Higher; the cis compound will have 12 different orientations and the trans compound will have only 3 different orientations.

8.79 (a) $W = 3$. (b) $W = 12$. (c) Initially, one of the three-atom systems had two atoms in higher energy states. In part (b), the system

will be at equilibrium when each three-atom system has one quantum of energy. Therefore, energy will flow from the system with two quanta to the system with none.

8.81 According to Trouton's rule, the entropy of vaporization of an organic liquid is a constant of approximately 85 $J{\cdot}mol^{-1} \cdot K^{-1}$. The relationship between entropy of fusion, enthalpy of fusion, and melting point is given by $\Delta S_{fus}° = \dfrac{\Delta H_{fus}°}{T_{fus}}$.

For Pb : $\Delta S_{fus}° = \dfrac{5100\ J}{600\ K} = 8.50\ J{\cdot}K^{-1}$. For Hg : $\Delta S_{fus}° = \dfrac{2290\ J}{234\ K} = 9.79\ J{\cdot}K^{-1}$. For Na : $\Delta S_{fus}° = \dfrac{2640\ J}{371\ K} = 7.12\ J{\cdot}K^{-1}$.

These numbers are reasonably close but clearly much smaller than the value associated with Trouton's rule.

8.83 Fe_2O_3 is thermodynamically more stable because $\Delta G_r°$ for the interconversion reaction is negative.

8.85 (a) $-110.0\ kJ{\cdot}mol^{-1}$; (b) $7.14 \times 10^{-2}\ mol{\cdot}L^{-1}$

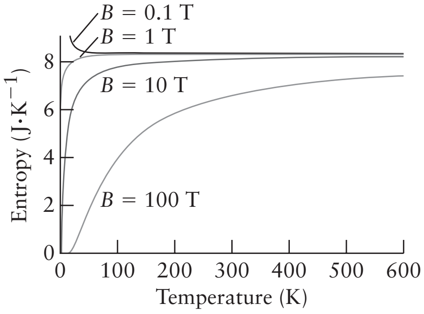
8.87 (a) no; (b) positive; (c) positional disorder; (d) thermal disorder; (e) dispersal of matter

8.89 (a) method (i); (b) method (i); (c) no

8.91 The entries all correspond to aqueous ions. The fact that they are negative is due to the reference point that has been established. Because ions cannot actually be separated and measured independently, a reference point that defines $S_m°(H^+, aq) = 0$ has been established. This definition is then used to calculate the standard entropies for the other ions. The fact that they are negative will arise in part because the solvated ion $M(H_2O)_x{}^{n+}$ will be more ordered than the isolated ion and solvent molecules ($M^{n+} + xH_2O$)

8.93 (a) 8.57 kJ at 298 K, −0.35 kJ at 373 K, −6.29 kJ at 423 K. (b) 0 kJ. (c) The discrepancy arises because the enthalpy and entropy values calculated from the tables are not rigorously constant with temperature. Better values would be obtained by using the actual enthalpy and entropy of vaporization measured at the boiling point.

8.95



8.97 $e^{-\Delta E/kT}$ will tend toward 1 as $T \longrightarrow \infty$.

8.99 (a) Since standard molar entropies increase with temperature (more translational, vibrational, and rotational motion), the $-T\Delta S_m°$ term becomes more negative at higher temperatures. (b) For gases with translational motion, their increase in standard molar entropy on heating, is much larger than for solids and liquids. Therefore, their $-T\Delta S_m°$ term is more negative.

8.101 The dehydrogenation of cyclohexane to benzene follows the equation $C_6H_{12}(l) \longrightarrow C_6H_6(l) + 3\ H_2(g)$. The reaction of ethyne with hydrogen can be examined similarly:

$C_2H_2(g) + H_2(g) \longrightarrow C_2H_6(g)$

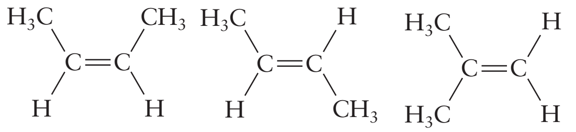
$$\begin{aligned}\Delta G_r° &= \Delta G_f°(C_2H_6, g) - \Delta G_f°(C_2H_2, g)\\ &= (-32.82\ kJ{\cdot}mol^{-1}) - 68.15\ kJ{\cdot}mol^{-1}\\ &= -100.97\ kJ{\cdot}mol^{-1}\end{aligned}$$

We can now combine these two reactions:

$$\begin{array}{ll} C_6H_{12}(l) \longrightarrow C_6H_6(l) + 3\ H_2(g) & \Delta G_r° = +97.6\ kJ{\cdot}mol^{-1} \\ +3[C_2H_2(g) + H_2(g) \longrightarrow C_2H_6(g)] & \Delta G_r° = 3(-100.97\ kJ{\cdot}mol^{-1}) \\ \hline C_6H_{12}(l) + 3\ C_2H_2(g) \longrightarrow C_6H_6(l) + 3\ C_2H_6(g) & \\ \Delta G_r° = -205.13\ kJ{\cdot}mol^{-1} & \end{array}$$

We can see that by combining these two reactions, the overall process becomes spontaneous. Essentially, we are using the energy of the favorable reaction to drive the nonfavorable process.

8.103



cis-2-Butene *trans*-2-Butene 2-Methylpropene

(a) (1) (2) (3)

(b) (1 ⟶ 2) $\Delta H_r° = -4.18\ kJ{\cdot}mol^{-1}$, $\Delta S_r° = -4.33\ J{\cdot}K^{-1}{\cdot}mol^{-1}$, $\Delta G_r° = -2.89\ kJ{\cdot}mol^{-1}$; (1 ⟶ 3) $\Delta H_r° = -9.91\ kJ{\cdot}mol^{-1}$, $\Delta S_r° = -7.11\ J{\cdot}K^{-1}{\cdot}mol^{-1}$, $\Delta G_r° = -7.79\ kJ{\cdot}mol^{-1}$; (2 ⟶ 3) $\Delta H_r° = -5.73\ kJ{\cdot}mol^{-1}$, $\Delta S_r° = -2.78\ J{\cdot}K^{-1}{\cdot}mol^{-1}$, $\Delta G_r° = -4.90\ kJ{\cdot}mol^{-1}$;
(c) The most stable of the three compounds is 2-methylpropene.
(d) $S_m°(1) > S_m°(2) > S_m°(3)$.

8.105 (a) $2\ NaN_3(s) \longrightarrow 3\ N_2(g) + 2\ Na(g)$.
(b) $\Delta S_r°$ is positive because a gas is produced (from a solid).
(c) Azide ion, $-\frac{1}{3}$; nitrogen, 0; nitrogen is oxidized. (d) $688.4\ J{\cdot}K^{-1}{\cdot}mol^{-1}$;
(e) $-3.39 \times 10^4\ J{\cdot}mol^{-1}$; (f) yes. (g) yes, lowered

9.57 (a) 1.84; (b) $0.318\ mol{\cdot}kg^{-1}$; (c) 83.8%
9.59 The compound that freezes at the lower temperature will have the largest $|\Delta T_f|$ (assuming that $i = 1$, since we are told they are both

molecular compounds). Since the same mass of each compound is present in the same amount of solvent for each solution, the compound with the lower molar mass will have the larger number of moles and therefore the larger $|\Delta T_f|$ (since the compound with the largest molar amount present will have the largest amount of solute particles present). Since compound A caused the water to freeze at a lower T than compound B, compound A must have the lower molar mass. Compound B must therefore have the greater molar mass.

9.77 63 g

9.79 Raoult's law applies to the vapor pressure of the mixture, so positive deviation means that the vapor pressure is higher than expected for an ideal solution. Negative deviation means that the vapor pressure is lower than expected for an ideal solution. Negative deviation will occur when the interactions between the different molecules are somewhat stronger than the interactions between molecules of the same kind. (a) For methanol and ethanol, we expect the types of intermolecular attractions in the mixture to be similar to those in the component liquids, so that an ideal solution is predicted. (b) For HF and $\mathbf{H_2O}$, the possibility of intermolecular hydrogen bonding between water and HF would suggest that negative deviation would be observed, which is the case. HF and $\mathbf{H_2O}$ form an azeotrope that boils at **111°C,** a temperature higher than the boiling point of either HF (**19.4°C**) or water. (c) Because hexane is nonpolar and water is polar with hydrogen bonding, we would expect a mixture of these two to exhibit positive deviation (the interactions between the different molecules would be weaker than the intermolecular forces between like molecules). Hexane and water do form an azeotrope that boils at 61.6°C, a temperature below the boiling point of either hexane or water.

9.81 A *foam* is a colloid formed by suspending a gas in a liquid or a solid matrix, while a *sol* is a suspension of a solid in a liquid. Some examples of foams are styrofoam and soapsuds; examples of sols are muddy water and mayonnaise.

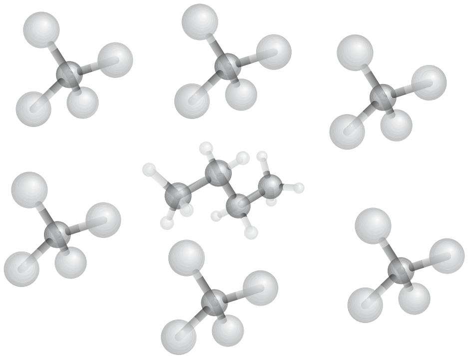
9.83 Colloids will reflect or scatter light while true solutions do not (this is known as the Tyndall effect).

9.85 Water is a polar molecule and as a result will orient itself differently around cations and anions, aligning its dipole in such a way as to present the most favorable interaction possible.

9.87 (a) stronger; (b) low; (c) high; (d) weaker; (e) weak, low; (f) low; (g) strong, high

9.89 (a, b) Viscosity and surface tension decrease with increasing temperature; at high temperatures the molecules readily move away from their neighbors because of increased kinetic energy. (c, d) Evaporation rate and vapor pressure increase with increasing temperature because the kinetic energy of the molecules increase with temperature, and the molecules are more likely to escape into the gas phase.

9.91 (a) Butane will dissolve in tetrachloromethane.



(b) Calcium chloride will dissolve water.

9.93 (a) 78.5%; (b) Some of the water vapor in the air would condense as dew or fog.

9.95 (a) If $mass_{solute}$ appears greater, M_{solute} appears greater than the actual molar mass, as $mass_{solute}$ occurs in the numerator above. Also, the ΔT measured will be smaller because less solute will actually be dissolved. This has the same effect as increasing the apparent M_{solute}. (b) Because the true $mass_{solvent} = d \times V$, if $d_{solvent}$ is less than 1.00 $\mathbf{g\cdot cm^{-3}}$, then the true $mass_{solvent}$ will be less than the assumed mass. M_{solute} is inversely proportional to $mass_{solvent}$, so an artificially high $mass_{solvent}$ will lead to an artificially low M_{solute}. (c) If the true freezing point is higher than the recorded freezing point, the true $\Delta T <$ assumed ΔT, or the assumed $\Delta T >$ true ΔT, and M_{solute} appears less than the actual M_{solute}, as ΔT occurs in the denominator. (d) If not all the solute dissolved, the true $mass_{solute} <$ assumed $mass_{solute}$ or the assumed $mass_{solute} >$ true $mass_{solute}$, and M_{solute} appears greater than the actual M_{solute}, as $mass_{solute}$ occurs in the numerator.

9.97 The water Coleridge referred to was seawater. The boards shrank due to osmosis (a net movement of water from the cells of the wood to the saline water). You can't drink seawater: osmosis would cause a net flow of water from the cells of the body to the saline-enriched surround solution and the cells would die.

9.99 (a) $4.8 \times 10^3\ g\cdot mol^{-1}$. (b) -3.9×10^{-4} °C. (c) The freezing point change is so small that it cannot be measured accurately, so osmotic pressure would be the preferred method for measuring the molecular weight.

9.101 $76\ g\cdot mol^{-1}$

9.103 (a)

$$\ln P = -\frac{38\,200\ J\cdot mol^{-1}}{8.314\ J\cdot K^{-1}\cdot mol^{-1}}\cdot\frac{1}{T} + \frac{113.0\ J\cdot K^{-1}\cdot mol^{-1}}{8.314\ J\cdot K^{-1}\cdot mol^{-1}}$$

$$= -\frac{4595\ K}{T} + 13.59$$

(b) The relationship to plot is ln P versus $\frac{1}{T}$. This should result in a straight line whose slope is $-\frac{\Delta H°_{vap}}{R}$ and whose intercept is $\frac{\Delta S°_{vap}}{R}$. The pressure must be given in atm for this relationship, because atm is the standard state condition. (c) 30. Torr; (d) 338.1 K

9.105 (a) $56.9\ g\cdot mol^{-1}$. This experimental molar mass of acetic acid is less than the known molecular mass of the acid ($60.6\ g\cdot mol^{-1}$), indicating that the acid is dissociating in solution, giving an $i > 1$. (b) $116\ g\cdot mol^{-1}$; this experimental molar mass of acetic acid is significantly higher than the known molar mass of the acid ($60.0\ g\cdot mol^{-1}$), indicating that the acid is forming diniers in solution, giving an $i < 1$. A van't Hoff factor less than 1 indicates that acetic acid is not completely dissolved in the benzene, or that acetic acid molecules are aggregating together in solution.

9.107 (a) $y = -3358.714x + 12.247$; (b) $28\ kJ\cdot mol^{-1}$; (c) $1.0 \times 102\ J\cdot K^{-1}\cdot mol^{-1}$; (d) 2.7×10^2 K; (e) 2.1×10^2 K

9.109 The critical temperatures are CH_4, **−82.1°C;** C_2H_6, 32.2°C; C_3H_8, 96.8°C; C_4H_{10}, 152°C. The critical temperatures increase with increasing mass, showing the influence of the stronger London forces.

9.111 (a) 195 Torr in flask A, 222 Torr in flask B. (b) $x_{acetone,\ gas} = 0.70$, $x_{chloroform,\ gas} = 0.30$, $x_{acetone} = 0.67$, $x_{chloroform} = 0.33$. (c) The solution shows negative deviation from Raoult's law. This means that the molecules of acetone and chloroform attract each other slightly more than molecules of the same kind. Under such circumstances, the vapor pressure is lower than expected from the ideal calculation. This will give rise to a

high-boiling azeotrope. The gas phase composition will also be slightly different from that calculated from the ideal state, but whether acetone or chloroform would be richer in the gas phase depends on which side of the azeotrope the composition lies. Because we are not given the composition of the azeotrope, we cannot state which way the values will vary.

9.113 The vapor pressure is more sensitive if ΔH_{vap} is large. The fact that ΔH_{vap} is large indicates that it takes a lot of energy to volatilize the sample, which means that the intermolecular forces are weaker. Hence, we expect the ratio P_1/P_2 in the Clausius–Clapeyron equation to be larger.

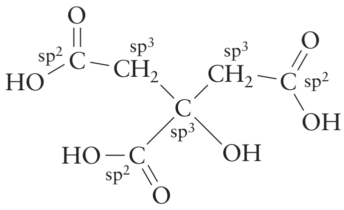
9.115 0.32 mg A

9.117 27.3 g

9.119 18.5 L

9.121 The nonpolar chains of both the surfactant and pentanol will interact to form a hydrophobic region with the heads of the two molecules pointing away from this region toward the aqueous solution. To prevent the heads of the shorter pentanol molecules from winding up in the hydrophobic region, the layered structure might be comprised of a water region, a surfactant layer (heads pointing toward the water), a pentanol layer (with tails pointing toward the hydrophobic tails of the surfactant), and then another aqueous region.

9.123 (a) The hybridization of the carbon atoms in citric acid is

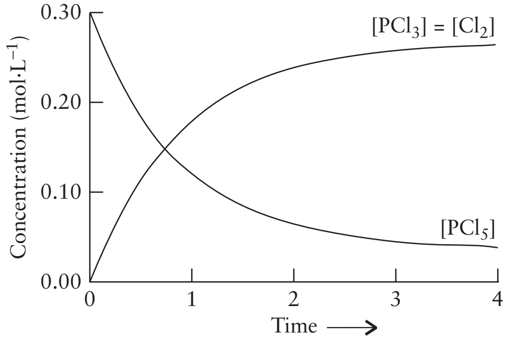


(b) yes; (c) solid, soluble; (d) 0.3 M; (e) 2×10^1 g; (f) 1 g

Chapter 10

10.1 (a) False, equilibrium is dynamic. At equilibrium, the concentrations of reactants and products will not change, but the reaction will continue to proceed in both directions. (b) False, equilibrium reactions are affected by the presence of both products and reactants. (c) False, the value of the equilibrium constant is not affected by the amounts of reactants or products added as long as the temperature is constant. (d) true

10.3



10.5 (a) flask 3; (b) 54.5%; (c) 0.16

10.7 (a) $CH_4(g) + 2\ O_2(g) \rightleftharpoons CO_2(g) + 2\ H_2O(g)$;

$$K_C = \frac{[CO_2][H_2O]^2}{[CH_4][O_2]^2}$$

(b) $I_2(g) + 5\ F_2(g) \rightleftharpoons 2\ IF_5(g)$; $K_C = \dfrac{[IF_5]^2}{[I_2][F_2]^5}$

(c) $2\ NO_2(g) + F_2(g) \rightleftharpoons 2\ FNO_2(g)$; $K_C = \dfrac{[FNO_2]^2}{[F_2][NO_2]^2}$

10.9 (a) Because the volume is the same, the number of moles of O_2 is larger in the second experiment. (b) Because K_c is a constant and the denominator is larger in the second case, the numerator must also be larger, so the concentration of O_2 is larger in the second case. (c) Although $[O_2]^3/[O_3]^2$ is the same, $[O_2]/[O_3]$ will be different, a result seen by solving for K_c in each case. (d) Because K_c is a constant, $[O_2]^3/[O_3]^2$ is the same. (e) Because $[O_2]^3/[O_3]^2$ is the same, its reciprocal must be the same.

10.11 48.8 for condition 1, 48.9 for conditions 2 and 3

10.13 (a) $\dfrac{1}{P_{BCl_3}{}^2}$; (b) $[H_3PO_4]^4\ [H_2S]^{10}$; (c) $\dfrac{P_{BrF_3}{}^2}{P_{Br_2}\,P_{F_2}{}^3}$

Halogen	Bond dissociation energy ($\text{kJ} \cdot \text{mol}^{-1}$)	$\Delta G°$ ($\text{kJ} \cdot \text{mol}^{-1}$)
fluorine	146	19.1
chlorine	230	47.9
bromine	181	42.8
iodine	139	5.6

(b) There is a correlation between the bond dissociation energy and the free energy of formation of the atomic species, but the relationship is clearly not linear. For the three heavier halogens, there is a trend to decreasing free energy of formation of the atoms as the element becomes heavier, but fluorine is anomalous. The F—F bond energy is lower than expected, owing to repulsions of the lone pairs of electrons on the adjacent F atoms because the F—F bond distance is so short.
10.109 (a) 4.5×10^{-29}; (b) 0.285 bar or 0.289 atm; (c) 3.6×10^{-15} bar or 3.6×10^{-15} atm; (d) 846 mL

10.115 (a) 11.2. (b) If NO_2 is added, the equilibrium will shift to produce more N_2O_4. The amount of NO_2 will be greater than initially present, but less than the $3.13\ \text{mol·L}^{-1}$ present immediately upon making the addition. K_c will not be affected. (c) $[N_2O_4] = 0.64\ \text{mol·L}^{-1}$, $[NO_2] = 2.67\ \text{mol·L}^{-1}$
10.117 H_2O: 24 Torr; D_2O: 21 Torr. The answer is that D has a lower zero-point energy than H. This makes the D_2O—D_2O "hydrogen bond" stronger than the H_2O—H_2O hydrogen bond. Because the hydrogen bond is stronger, the intermolecular forces are stronger, the vapor pressure is lower, and the boiling point is higher. Potential energy curves for the O—H and O—D bonds as a function of distance: ΔE = energy required to break O—H or O—D bond.

11.41
$(CH_3)_2NH_2^+(14.00 - 3.27 = 10.73) < {}^+NH_3OH(14.00 - 7.97 = 6.03) < HNO_2(3.37) < HClO_2(2.00)$
11.43 $E^-(14.00 - 3.45 = 10.55) < CH_3CO_2^-(14.00 - 4.75 = 9.25) < C_5H_5N(8.75) \ll NH_3(4.75)$

11.45 (a) strong; (b) weak; (c) weak; (d) weak; (e) weak; (f) strong; (g) weak
11.47 The larger the K_a, the stronger the corresponding acid. 2,4,6-Trichlorophenol is the stronger acid because the chlorine atoms have a greater electron-withdrawing power than the hydrogen atoms present in the unsubstituted phenol.
11.49 The larger the pK_a of an acid, the stronger the corresponding conjugate base; hence, the order is aniline < ammonia < methylamine < ethylamine.
11.51 For oxoacids, the greater the number of highly electronegative O atoms attached to the central atom, the stronger the acid. This effect is related to the increased oxidation number of the central atom as the number of O atoms increases. Therefore, HIO_3 is the stronger acid, with the lower pK_a.
11.53 (a) HCl is the stronger acid, because its bond strength is much weaker than the bond in HF, and bond strength is the dominant factor in determining the strength of binary acids. (b) $HClO_2$ is stronger; there is one more O atom attached to the Cl atom in $HClO_2$ than in HClO. The additional O in $HClO_2$ helps to pull the electron of the H atom out of the H—O bond. The oxidation state of Cl is higher in $HClO_2$ than in HClO. (c) $HClO_2$ is stronger; Cl has a greater electronegativity than Br, making the H—O bond in $HClO_2$ more polar than in $HBrO_2$. (d) $HClO_4$ is stronger; Cl has a greater electronegativity than P. (e) HNO_3 is stronger. The explanation is the same as that for part (b). HNO_3 has one more O atom. (f) H_2CO_3 is stronger; C has greater electronegativity than Ge. See part (c).
11.55 (a) The $—CCl_3$ group that is bonded to the carboxyl group, —COOH, in trichloroacetic acid is more electron withdrawing than the $—CH_3$ group in acetic acid. Thus, trichloroacetic acid is the stronger acid. (b) The $—CH_3$ group in acetic acid has electron-donating properties, which means that it is less electron withdrawing than the —H attached to the carboxyl group in formic acid, HCOOH. Thus, formic acid is a slightly stronger acid than acetic acid. However, it is not nearly as strong as trichloroacetic acid. The order is $CCl_3COOH \gg HCOOH > CH_3COOH$.

11.57 (a) pH = 2.72, pOH = 11.28, 0.95%. (b) pH = 0.85, pOH = 13.15, 70%. (c) pH = 2.22, pOH = 11.78, 3.0%. (d) Acidity increases when the hydrogen atoms in the methyl group of acetic acid are replaced by atoms that have a higher electronegativity, such as chlorine.
11.59 (a) $K_a = 0.09$, pK_a = 1.0; (b) $K_b = 5.6 \times 10^{-4}$, pK_b = 3.25
11.61 (a) pOH = 3.00, pH = 11.00, 1.8%; (b) pOH = 4.38, pH = 9.62, 0.026%; (c) pOH = 2.32, pH = 11.68, 1.4%; (d) pOH = 3.96, pH = 10.04, 2.5%
11.63 (a) 0.021 mol·L^{-1}; (b) 1.5×10^{-2} mol·L^{-1}
11.65 pH = 2.58, $K_a = 6.5 \times 10^{-5}$
11.67 pH = 11.83, $K_b = 4.8 \times 10^{-5}$
11.69 7.7×10^{-9}
11.71

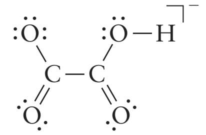
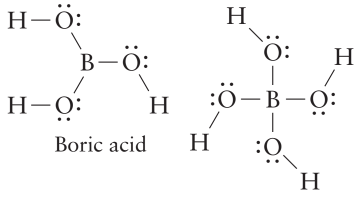
11.111 (a) 6.35, 7.35; (b) 6.34, 6.96
11.113 (a) 6.69, 7.22; (b) 6.64, 6.92
11.115 (a) Acid (1) is a strong acid because it totally dissociates. (b) Acid (3) has the strongest base because it is the weakest acid. (c) Acid (3) has the largest pK_a. Since p$K_a = -\log K_a$, the smallest K_a value will result in the largest pK_a.
11.117 The apparent motion of hydronium and hydroxide ions is not as dependent on the diffusion of individual ions as other ions; they are formed and reformed as protons are transferred from and to water molecules in solution. Autoprotolysis allows rapid proton transfer between water molecules.
11.119 (a) C_2HNaO_4
(b)



(c) sodium oxalate, amphiprotic, 2.71
11.121 The Lewis structure of boric acid is



Boric acid

Conjugate base

(a) no. (b) Boric acid acts as a Lewis acid because it accepts electron pairs (OH^-) from water, but its acidity is not due to its dissociation.
11.123 (a) Nitrous acid will act like a strong acid because its conjugate base, the nitrite ion, is a weaker base than the acetate ion. The presence of acetate ions will shift the proton transfer equilibrium of nitrous acid toward the products (NO_2^- and H_3O^+) by consuming H_3O^+, which will increase the apparent K_a of nitrous acid. Carbonic acid is a weaker acid than acetic acid, so no shift in equilibrium occurs. (b) Ammonia will act like a strong base because its conjugate acid, the ammonium ion, is a weaker acid than acetic acid. The presence of acetic acid will shift the proton transfer equilibrium of ammonia with water toward the products (NH_4^+ and OH^-) by consuming OH^-, which will increase the apparent K_b of ammonia.
11.125 6.9×10^{-4}
11.127 (a) $D_2O + D_2O \rightleftharpoons D_3O^+ + OD^-$; (b) 14.870; (c) 3.67×10^{-8} mol·L^{-1}; (d) pD = pOD = 7.435; (e) pD + pOD = pK_{hw} = 14.870
11.129 2.9% deprotonated; 271 K
11.131 1.3×10^2 J·mol^{-1}
11.133 The greater difference in the acidity constants, K_{a1} and K_{a2}, of adipic acid and those of oxalic acid is due to the structural differences of these two acids. Adipic acid has four CH_2 groups between the two carboxylic groups and this will cause a greater electron delocalization, which stabilizes the carboxylic anions. As a result, the two protons on the adipic acid can be easily removed almost simultaneously. This is why the two pK_a values are so close. However, oxalic acid lacks the CH_2 groups between the two carboxylic groups and a weaker electron delocalization ability of the anions results a large separation of the two pK_a values.
11.135 (a) HbO_2^- concentration will be lower in the tissues. (b) HbO_2^- concentration will increase.
11.137 (a) CO_2 will react with water to form carbonic acid, H_2CO_3. Determine the concentration of H_3O^+. Under the specified conditions, pH = 5.75. (b) $[H_2CO_3] = 4.4 \times 10^{-3}$ mol·L^{-1}; $[HCO_3^-] = 1.2 \times 10^{-4}$ mol·L^{-1}; $[CO_3^{2-}] = 4.2 \times 10^{-10}$ mol·L^{-1}. (c) 50 kg. (d) 4.82. (e) 4.52. (f) 86.9 kg

Chapter 12

12.1 (a) When solid sodium acetate is added to an acetic acid solution, the concentration of H_3O^+ decreases because the equilibrium $HC_2H_3O_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + C_2H_3O_2^-(aq)$ shifts to the left to relieve the stress imposed by the increase of $[C_2H_3O_2^-]$ (Le Chatelier's principle).
(b) When HCl is added to a benzoic acid solution, the percentage of benzoic acid that is deprotonated decreases because the equilibrium $C_6H_5COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + C_6H_5CO_2^-(aq)$ shifts to the left to relieve the stress imposed by the increased $[H_3O^+]$ (Le Chatelier's principle).
(c) When solid NH_4Cl is added to an ammonia solution, the concentration of OH^- decreases because the equilibrium $NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$ shifts to the left to relieve the stress imposed by the increased $[NH_4^+]$ (Le Chatelier's principle). Because $[OH^-]$ decreases, $[H_3O^+]$ increases and pH decreases.
12.3 (a) pH = pK_a = 3.08, $K_a = 8.3 \times 10^{-4}$; (b) 2.77
12.5 (a) 6.1×10^{-10} mol·L^{-1}; (b) 1.7×10^{-11} mol·L^{-1}; (c) 2.5×10^{-10} mol·L^{-1}; (d) 5.9×10^{-9} mol·L^{-1}
12.7 (a) pH = 1.62, pOH = 12.38; (b) pH = 1.22, pOH = 12.78; (c) pH = 1.92, pOH = 12.08
12.9 (a) 9.46; (b) 9.71; (c) 9.31
12.11 (a) pH = 6.3, change of 1.5; (b) pH = 4.58, change of −0.17
12.13 increases by 1.16
12.15 $\dfrac{[ClO^-]}{[HClO]} = 9.3 \times 10^{-2}$
12.17 (a) 2–4; (b) 3–5; (c) 11.5–13.5; (d) 6–8; (e) 5–7

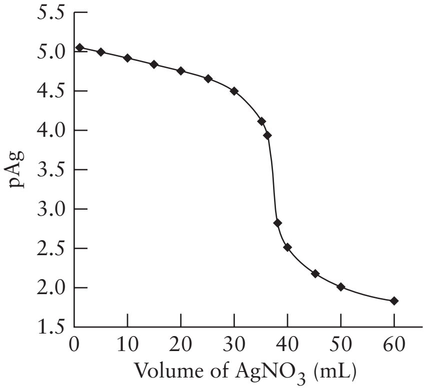
12.61 (a) 1.0×10^{-12} $mol{\cdot}L^{-1}$; (b) 3.1×10^{-5} $mol{\cdot}L^{-1}$; (c) 2.0×10^{-3} $mol{\cdot}L^{-1}$; (d) 0.20 $mol{\cdot}L^{-1}$
12.63 (a) 1.6×10^{-5} $mol{\cdot}L^{-1}$; (b) 2.7×10^{2} μg
12.65 (a) 6.00; (b) 6.18
12.67 (a) yes; (b) no
12.69 (a) first to last: $Ni(OH)_2$, $Mg(OH)_2$, $Ca(OH)_2$; (b) $Ni(OH)_2$ at pH ≈ 7, $Mg(OH)_2$ at pH ≈ 10, $Ca(OH)_2$ at pH ≈ 13
12.71 The solubility difference is greatest between the two carbonates, and $CO_3^{2-}$is the better choice of anion.
12.73 1.8×10^{-9} $mol{\cdot}L^{-1}$
12.75 (a) $CaF_2(s) + 2H_2O(l) \rightleftharpoons$ $Ca^{2+}(aq) + 2HF(aq) + 2OH^-(aq)$
$K = K_w{\cdot}K_b^2 = (4.0 \times 10^{-11})(2.9 \times 10^{-11})^2 = 3.4 \times 10^{-32}$
(b) 2.0×10^{-4} $mol{\cdot}L^{-1}$; (c) 4×10^{-4} $mol{\cdot}L^{-1}$

12.77 2.0×10^{-3} $mol{\cdot}L^{-1}$
12.79 The two salts can be distinguished by their solubility in 1.0 $mol{\cdot}L^{-1}$ NH_3. The AgCl will dissolve, but most of the AgI will not.
12.81 In order to use qualitative analyses, the sample must first be dissolved. This can be accomplished by digesting the sample with concentrated HNO_3 and then diluting the resulting solution. HCl or H_2SO_4
could not be used because some of the metal compounds formed would be insoluble, whereas all of the nitrates would dissolve. Once the sample is dissolved and diluted, an aqueous solution containing chloride ions can be introduced. This should precipitate the Ag^+ as AgCl but would leave the bismuth and nickel in solution, as long as the solution is acidic. The remaining solution can then be treated with H_2S. In acidic solution, Bi_2S_3 will precipitate but NiS will not. Once the Bi_2S_3 has been precipitated, the pH of the solution can be raised by the addition of base. Once this is done, NiS should precipitate.
12.83 0.260 $mol{\cdot}L^{-1}$ in both acetic acid and sodium acetate
12.85 (a) 2.8; (b) 5.7; (c) $HOOCCH_2CO_2^-$
12.87 2.8×10^{-2}
12.89 2.2×10^{-3} M
12.91 If the two pK_a values of a diprotic acid are far apart (≥1000), there will be two stoichiometric points observed. If the two pK_a values of a diprotic acid are close (<500) (due to the electron delocalization of anions), like those of tartaric acid, there will be one stoichiometric point observed (i.e., two protons are titrated at about the same time). The titration curve in this case is not very steep due to the overlap titration of the first proton and the second proton.
12.93 The K_{sp} values from Table 12.4 are
Cu^{2+}, 1.3×10^{-36}; Co^{2+}, 5×10^{-22}; Cd^{2+}, 4×10^{-29}. All the salts have the same expression for K_{sp}, $K_{sp} = [M^{2+}][S^{2-}]$, so the compound with the smallest K_{sp}will precipitate first, in this case CuS.
12.95 (a) 0.0796 $mol{\cdot}L^{-1}$. (b) At the stoichiometric point, $pAg^+ = 3.94$.



12.97 (a) $SO_2(g) + H_2O(l) \rightleftharpoons H_2SO_3(aq)$; (b) 5×10^{-7} mol; (c) 1.8 ppm
12.99 −345.65 $kJ{\cdot}mol^{-1}$
12.101 (a) 3×10^{-18} mol; (b) pH = 5.8, change = 0.3
12.103 (a) 4.93; (b) 2.08 g
12.105 (a) 9.3×10^{-11} $mol{\cdot}L^{-1}$. (b) $[OH^-] = 2.8 \times 10^{-10}$ M; pH = 4.45. (c) Result in (b) is not reasonable because the OH^- from water is ignored. $[OH^-]_{water} = 1.0 \times 10^{-7}$ M. Actually, $[OH^-] = 1.0 \times 10^{-7}$ M in a saturated solution of $Fe(OH)_3$ because the $[OH^-]$ from $Fe(OH)_3$ is much smaller than the $[OH^-]$ from water; pH = 7.0. (d) 5.0×10^{-4}. (e) 5.3 g. (f) 60.1%

Chapter 13

13.1 (a) Cr reduced from 6+ to 3+; C oxidized from 2− to 1−; (b) $C_2H_5OH(aq) \longrightarrow C_2H_4O(aq) + 2\ H^+(aq) + 2\ e^-$; (c) $Cr_2O_7^{2-}(aq) + 14\ H^+(aq) + 6\ e^- \longrightarrow 2\ Cr^{3+}(aq) + 7\ H_2O(l)$; (d) $8\ H^+(aq) + Cr_2O_7^{2-}(aq) + 3\ C_2H_5OH(aq) \longrightarrow 2\ Cr^{3+}(aq) + 3\ C_2H_4O(aq) + 7\ H_2O(l)$

13.3 (a) $4\ Cl_2(g) + S_2O_3^{2-}(aq) + 5\ H_2O(l) \longrightarrow 8\ Cl^-(aq) + 2\ SO_4^{2-}(aq) + 10\ H^+(aq)$; Cl_2 is the oxidizing agent and $S_2O_3^{2-}$ is the reducing agent.
(b) $2\ MnO_4^-(aq) + H^+(aq) + 5\ H_2SO_3(aq) \longrightarrow 2\ Mn^{2+}(aq) + 3\ H_2O(l) + 5\ HSO_4^-(aq)$; MnO_4^- is the oxidizing agent and H_2SO_3 is the reducing agent.
(c) $Cl_2(g) + H_2S(aq) \longrightarrow 2\ Cl^-(aq) + S(s) + 2\ H^+(aq)$; Cl_2 is the oxidizing agent and H_2S is the reducing agent.
(d) $H_2O(l) + Cl_2(g) \longrightarrow HOCl(aq) + H^+(aq) + Cl^-(aq)$; Cl_2 is both the oxidizing and the reducing agent.

13.5 (a) $3\ O_3(g) + Br^-(aq) \longrightarrow 3\ O_2(g) + BrO_3^-(aq)$; O_3 is the oxidizing agent and Br^- is the reducing agent.
(b) $3\ Br_2(l) + 6\ OH^-(aq) \longrightarrow 5\ Br^-(aq) + BrO_3^-(aq) + 3\ H_2O(l)$; Br_2 is both the oxidizing agent and the reducing agent.
(c) $2\ Cr^{3+}(aq) + 4\ OH^-(aq) + 3\ MnO_2(s) \longrightarrow 2\ CrO_4^{2-}(aq) + 2\ H_2O(l) + 3\ Mn^{2+}(aq)$; Cr^{3+} is the reducing agent and MnO_2 is the oxidizing agent.
(d) $P_4(s) + 3\ H_2O(l) + 3\ OH^-(aq) \longrightarrow 3\ H_2PO_2^-(aq) + PH_3(g)$; $P_4(s)$ is both the oxidizing and the reducing agent.

13.7 half-reactions: $P_4S_3(aq) + 28\ H_2O(l) \longrightarrow 4\ H_3PO_4(aq) + 3\ SO_4^{2-}(aq) + 44\ H^+(aq) + 38\ e^-$; $NO_3^-(aq) + 4\ H^+(aq) + 3\ e^- \longrightarrow NO(aq) + 2\ H_2O(l)$
overall reaction: $3\ P_4S_3(aq) + 38\ NO_3^-(aq) + 20\ H^+(aq) + 8\ H_2O(l) \longrightarrow 12\ H_3PO_4(aq) + 9\ SO_4^{2-}(aq) + 38\ NO(g)$

13.9 (a) $-2.08 \times 10^5\ J{\cdot}mol^{-1}$; (b) $7.47 \times 10^5\ J{\cdot}mol^{-1}$

13.11 (a) cathode: $Ag^+(aq) + e^- \longrightarrow Ag(s)$, anode: $Ni^{2+}(aq) + 2\ e^- \longrightarrow Ni(s)$, overall: $2\ Ag^+(aq) + Ni(s) \longrightarrow 2\ Ag(s) + Ni^{2+}(aq)$;
(b) anode: $2\ H^+(aq) + 2e^- \longrightarrow H_2(g)$, cathode: $Cl_2(g) + 2e^- \longrightarrow 2\ Cl^-(aq)$, overall: $Cl_2(g) + H_2(g) \longrightarrow 2\ H^+(aq) + 2\ Cl^-(aq)$;
(c) anode: $Cu^{2+}(aq) + 2\ e^- \longrightarrow Cu(s)$, cathode: $Ce^{4+}(aq) + e^- \longrightarrow Ce^{3+}(aq)$, overall: $2\ Ce^{4+}(aq) + Cu(s) \longrightarrow Cu^{2+}(aq) + 2\ Ce^{3+}(aq)$;
(d) cathode: $O_2(g) + 2\ H_2O(l) + 4\ e^- \longrightarrow 4\ OH^-(aq)$, anode: $O_2(g) + 4\ H^+(aq) + 4\ e^- \longrightarrow 2\ H_2O(l)$, overall: $H_2O(l) \longrightarrow H^+(aq) + OH^-(aq)$
(e) anode: $Sn^{4+}(aq) + 2\ e^- \longrightarrow Sn^{2+}(aq)$, cathode: $Hg_2Cl_2(s) + 2\ e^- \longrightarrow 2\ Hg(l) + 2\ Cl^-(aq)$, overall: $Sn^{2+}(aq) + Hg_2Cl_2(s) \longrightarrow 2\ Hg(l) + 2\ Cl^-(aq) + Sn^{4+}(aq)$

13.13 (a) cathode: $Ni^{2+}(aq) + 2\ e^- \longrightarrow Ni(s)$, anode: $Zn^{2+}(aq) + 2\ e^- \longrightarrow Zn(s)$, $Zn(s)\ |\ Zn^{2+}(aq)\ ||\ Ni^{2+}(aq)\ |\ Ni(s)$
(b) cathode: $2[Ce^{4+}(aq) + e^- \longrightarrow Ce^{3+}(aq)]$, anode: $I_2(s) + 2\ e^- \longrightarrow 2\ I^-(aq)$, $Pt(s)\ |\ I^-(aq)\ |\ I_2(s)\ ||\ Ce^{4+}(aq), Ce^{3+}(aq)\ |\ Pt(s)$

14.45 $CH_2{=}CHCOOH + HCl \longrightarrow ClCH_2CH_2COOH$; intermediates: Cl^-, $CH_2{=}CHC(OH)_2{}^+$ and $ClCH_2CHC(OH)_2$
14.47 (a) $O_3 + O \longrightarrow 2\,O_2$; (b) Step 1: rate = $k[O_3][NO]$, bimolecular; Step 2: rate = $k[NO_2][O]$, bimolecular; (c) NO_2; (d) NO
14.49 rate = $k[NO][Br_2]$

14.51 If mechanism (a) were correct, the rate law would be rate = $k[NO_2][CO]$. But this expression does not agree with the experimental result and can be eliminated as a possibility. Mechanism (b) has rate = $k[NO_2]^2$ from the slow step. Step 2 does not influence the overall rate, but it is necessary to achieve the correct overall reaction; thus this mechanism agrees with the experimental data. Mechanism (c) is not correct, which can be seen from the rate expression for the slow step, rate = $k[NO_3]$ [CO]. [CO] cannot be eliminated from this expression to yield the experimental result, which does not contain [CO].
14.53 (a) true. (b) false. At equilibrium, the *rates* of the forward and reverse reactions are equal, *not the rate constants*. (c) false. Increasing the concentration of a reactant causes the rate to increase by providing more reacting molecules. It does not affect the rate constant of the reaction.
14.55 The overall rate of formation of A is rate = $-k[A] + k'[B]$. The first term accounts for the forward reaction and is negative as this reaction reduces [A]. The second term, which is positive, accounts for the back reaction which increases [A]. Given the 1:1 stoichiometry of the reaction, if no B was present at the beginning of the reaction, [A] and [B] at any time are related by the equation $[A] + [B] = [A]_0$ where $[A]_0$ is the initial concentration of A. Therefore, the rate law may be written

$$\frac{d[A]}{dt} = -k[A] + k'([A]_0 - [A]) = -(k + k')[A] + k'[A]_0$$

The solution of this first-order differential equation is

$$[A] = \frac{k' + ke^{-(k'+k)t}}{k' + k}[A]_0$$

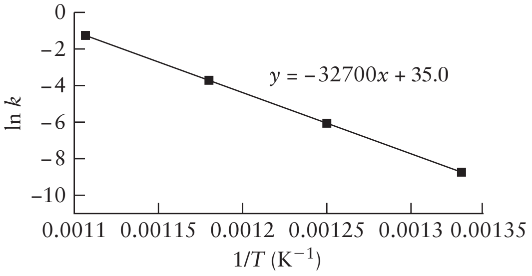
As $t \longrightarrow \infty$ the exponential term in the numerator goes to zero and the concentrations reach their equilibrium values given by

$$[A]_{eq} = \frac{k'[A]_0}{k' + k} \quad \text{and} \quad [B]_{eq} = [A]_0 - [A]_\infty = \frac{k[A]_0}{k + k'}$$

Taking the ratio of products over reactants we see that:

$$\frac{[B]_{eq}}{[A]_{eq}} = \frac{k}{k'} = K \text{ where } K \text{ is the equilibrium constant for the reaction.}$$

14.57



(a) 2.72×10^2 kJ·mol^{-1}; (b) 0.088 s^{-1}
14.59 39 kJ·mol^{-1}
14.61 2.5×10^9 L·mol^{-1}·s^{-1}
14.63 9.2×10^{-4}·s^{-1}
14.65 (a) 0.676. (b) endothermic. (c) Raising the temperature will increase the rate constant of the reaction with the higher activation barrier more than it will the rate constant of the reaction with the lower energy barrier. We expect the rate of the forward reaction to go up substantially more than for the reverse reaction in this case. k will increase more than k' and consequently the equilibrium constant K will increase. This is consistent with Le Chatelier's principle.
14.67 (a) 6×10^8; (b) 3×10^7
14.69 81 kJ·mol^{-1}
14.71 The overall reaction is $RCN + H_2O \longrightarrow RC(=O)NH_2$. $RC(=N^-)OH$ and $RC(=NH)OH$ are intermediates. The hydroxide ion serves as a catalyst for the reaction.
14.73 (a) false. A catalyst increases the rate of both the forward and reverse reactions by providing a completely different pathway. (b) true, although a catalyst may be poisoned and lose activity. (c) false. There is a completely different pathway provided for the reaction in the presence of a catalyst. (d) false. The position of the equilibrium is unaffected by the presence of a catalyst.

14.75 (a) To obtain the Michaelis–Menten rate equation, we will begin by employing the steady-state approximation, setting the rate of change in the concentration of the ES intermediate equal to zero:

$$\frac{d[ES]}{dt} = k_1[E][S] - k_1'[ES] - k_2[ES] = 0.$$

Rearranging gives $[E][S] = \left(\frac{k_2 + k_1'}{k_1}\right)[ES] = K_M[ES]$.

The total bound and unbound enzyme concentration, $[E]_0$, is given by $[E]_0 = [E] + [ES]$, and therefore, $[E] = [ES] - [E]_0$. Substituting this expression for [E] into the preceding equation, we obtain $([ES] - [E]_0)[S] = K_M [ES]$.

Rearranging to obtain [ES] gives: $[ES] = \frac{[E]_0[S]}{K_M + [S]}$.

From the mechanism, the rate of appearance of the product is given by *rate* = $k_2[ES]$. Substituting the preceding equation for [ES], we obtain

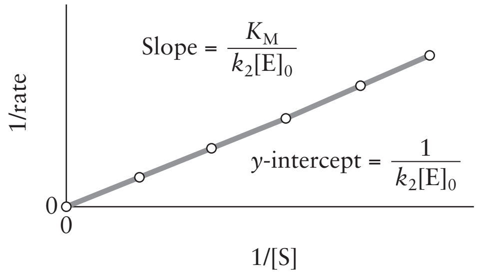
$$\text{Rate} = \frac{k_2[E]_0[S]}{K_M + [S]},$$

the Michaelis–Menten rate equation, which can be rearranged to obtain

$$\frac{1}{\text{rate}} = \frac{K_M}{k_2[E]_0[S]} + \frac{1}{k_2[E]_0}.$$

If one plots $\frac{1}{\text{rate}}$ versus $\frac{1}{[S]}$, the slope will be $\frac{K_M}{k_2[E]_0}$ and the y-intercept will be $\frac{1}{k_2[E]_0}$.

(b)



14.77 (a) rate = $k[NO]^2$, bimolecular; (b) rate = $k[Cl_2]$, unimolecular; (c) rate = $k[NO_2]^2$, bimolecular; (d) b and c
14.79 (a) $CH_3CH{=}CHCH_2Br$ because the positive charge on the reactive intermediate is on a primary carbon atom. This also agrees with the result that at high temperatures this is the predominant product as there is sufficient energy to overcome the larger activation energy. (b) Kinetic control predominates at low temperatures. The reaction pathway with the lower activation energy will predominate at low temperatures because the lower activation energy barrier results in a larger rate constant and therefore a faster reaction.
14.81 2.3 × 105 L·mol^{-1}·s^{-1}
14.83 (a) 5s (b) There should be four molecules at t = 8 s
14.85 (a) $CH_3CHO \longrightarrow CH_3 + CHO$, unimolecular
$[CH_3\cdots\cdots CHO]^\ddagger$
(b) $2I \longrightarrow I_2$, termolecular
$[I\cdots\cdots I\cdots\cdots Ar]^\ddagger$
(c) $O_2 + NO \longrightarrow NO_2 + O$, bimolecular
$[O\cdots\cdots O\cdots\cdots NO]^\ddagger$
14.87 13.5 mg
14.89 The anticipated rate for mechanism (i) is rate = $k[C_{12}H_{22}O_{11}]$, while the expected rate for mechanism (ii) is rate = $k[C_{12}H_{22}O_{11}][H_2O]$. The rate for mechanism (ii) will be pseudo-first-order in dilute solutions of sucrose because the concentration of water will not change. Therefore, in dilute solutions kinetic data cannot be used to distinguish between the two mechanisms. However, in a highly concentrated solution of sucrose, the concentration of water will change during the course of the reaction. As a result, if mechanism (ii) is correct the kinetics will display a first-order dependence on the concentration of H_2O while mechanism (i) predicts that the rate of the reaction is independent of $[H_2O]$.

14.91 (a) If step 2 is the slow step, if step 1 is a rapid equilibrium, and if step 3 is fast also, then our proposed rate law will be rate = $k_2[N_2O_2][H_2]$. Consider the equilibrium of step 1:
$k_1[NO]^2 = k_1'[N_2O_2]$; $[N_2O_2] = \frac{k}{k_1'}[NO]^2$

Substituting in our proposed rate law, we have

$$\text{rate} = k_2 \frac{k}{k_1'}[NO]^2[H_2] = k[NO]^2[H_2] \text{ where } k = k_2\left(\frac{k_1}{k_1'}\right)$$

The assumptions made above reproduce the observed rate law; therefore, step 2 is the slow step.

(c) third half-life $= t_3 = \frac{\text{constant}}{(\frac{1}{4}[A_0])^2} = \frac{16(\text{constant})}{[A_0]^2} = 16t_1$; fourth

half-life $= t_4 = \frac{\text{constant}}{(\frac{1}{8}[A_0])^2} = \frac{64(\text{constant})}{[A_0]^2} = 64t_1$; total time

$= t_1 + t_2 + t_3 + t_4 = t_1 + 4t_1 + 16t_1 + 64t_1 = 85t_1 = t_{1/16}$
14.103 The following plots are linear: (b), (c), (d), (f), (g).

14.105 (a) The overall reaction is $OCl^- + I^- \longrightarrow OI^- + Cl^-$.

(b) rate $= \frac{k_2k_1}{k_1'}\frac{[OCl^-][I^-]}{[OH^-]}$.

(c) The rate will decrease as pH increases. (d) If the reaction is carried out in an organic solvent, then H_2O is no longer the solvent and its concentration must be included in calculating the equilibrium concentration of HOCl: rate =

$$\frac{k_2k_1}{k_1'}\frac{[OCl^-][I^-][H_2O]}{[OH^-]}$$

14.107 To get an expression for $t_{1/2}$ in terms of n, we need to evaluate an integral such as

$$\int_{[A]_0}^{[A]} \frac{d[A]}{[A]^n} = -k\int_0^t dt = -kt$$

$$\frac{1}{n-1}\left(\frac{1}{[A]^{n-1}} - \frac{1}{[A]_0{}^{n-1}}\right) = kt$$

An expression for $t_{1/2}$ is then

$$\frac{1}{n-1}\left(\frac{2^{n-1}}{[A]_0{}^{n-1}} - \frac{1}{[A]_0{}^{n-1}}\right) = kt_{1/2}$$

$$\frac{1}{n-1}\left(\frac{2^{n-1} - 1}{[A]_0{}^{n-1}}\right) = kt_{1/2}$$

An expression for $t_{3/4}$ could be found by setting up $[A] = \frac{3}{4}[A]_0$

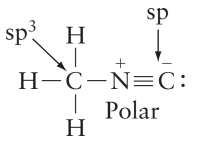
$$\frac{1}{n-1}\left(\frac{4^{n-1}}{3^{n-1}[A]_0{}^{n-1}} - \frac{1}{[A]_0{}^{n-1}}\right) = kt_{3/4}$$

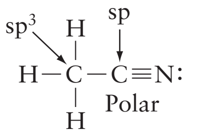
$$\frac{1}{n-1}\left(\frac{(4/3)^{n-1} - 1}{[A]_0{}^{n-1}}\right) = kt_{3/4}$$

The ratio $t_{1/2}/t_{3/4}$ is then

$$t_{1/2}/t_{3/4} = \left(\frac{2^{n-1} - 1}{(4/3)^{n-1} - 1}\right)$$

14.109 (a) methyl isonitrile





Cyanomethane

(b) -43 $kJ \cdot mol^{-1}$, cyanomethane. (c) $k' = 4.04 \times 10^{-15}$ s^{-1}, $t = 7.12 \times 10^{13}$ s. (d) Since $\Delta H°$ for this isomerization reaction is exothermic (-43 $kJ \cdot mol^{-1}$), the reaction profile has the product lower than the reactant. (e) 474 K. (f) Argon serves as a collision partner. Collisions between the $CH_3NC(g)$ and argon atoms provide the energy needed to overcome the activation energy and allow the isomerization reaction to proceed toward products. The argon atoms also serve as an energy sink, accepting the energy released during the isomerization reaction. (g) At high argon concentrations, collisions resulting in reaction are between the $CH_3NC(g)$ and argon atoms: $CH_3NC(g) + Ar(g) \longrightarrow CH_3CN(g) + Ar(g)$. Given this elementary reaction, one would predict that the reaction was first order with respect to $CH_3NC(g)$ concentration and would appear first order overall if the concentration of Ar(g) was large and unchanging. If, however, the concentration of Ar(g) was greatly reduced, the isomerization reaction would also proceed through collisions between $CH_3NC(g)$ molecules, making the reaction second order with respect to $CH_3NC(g)$.

Chapter 15

15.1 (a) nitrogen; (b) potassium; (c) gallium; (d) iodine
15.3 (a) sulfur; (b) selenium; (c) sodium; (d) oxygen
15.5 tellurium < selenium < oxygen
15.7 (a) antimony. (b) Antimony has a higher effective nuclear charge.
15.9 (a) bromide ion. (b) Bromide has the larger size.
15.11 $2\ K(s) + H_2(g) \longrightarrow 2\ KH(s)$
15.13 (a) saline; (b) molecular; (c) molecular; (d) metallic
15.15 (a) acidic; (b) amphoteric; (c) acidic; (d) basic
15.17 (a) CO_2; (b) B_2O_3
15.19 (a) $C_2H_2(g) + H_2(g) \longrightarrow H_2C{=}CH_2(g)$. Oxidation number of C in $C_2H_2 = -1$; of C in $H_2CRCH_2 = -2$, carbon has been reduced. (b) $CO(g) + H_2O(g) \longrightarrow CO_2(g) + H_2(g)$
(c) $BaH_2(s) + 2\ H_2O(l) \longrightarrow Ba(OH)_2 + 2\ H_2(g)$
15.21 (a) $H_2(g) + Cl_2(g) \xrightarrow{\text{light}} 2\ HCl(g)$;
(b) $H_2(g) + 2\ Na(l) \xrightarrow{\Delta} NaH(s)$;
(c) $P_4(s) + 6\ H_2(g) \longrightarrow 4\ PH_3(g)$; (d) $2\ Cu(s) + H_2(g) \longrightarrow 2\ CuH(s)$

15.23 The reason for this trend is mainly due to the trend of the electronegativity of the central atom (N < O < F), which makes F more partially negative, to attract H from another HF atom.

15.25 Lithium is the only Group 1 element that reacts directly with nitrogen to form lithium nitride; it reacts with oxygen to form mainly the oxide, whereas the other members of the group form mainly the peroxide or superoxide. Lithium exhibits the diagonal relationship that is common to many first members of a group. Li is similar in many of its compounds to the compounds of Mg. This behavior is related to the small ionic radius of Li^+, 58 pm, which is closer to the ionic radius of Mg^{2+}, 72 pm, but substantially less than that of Na^+, 102 pm.

15.27 (a) $4\,Na(s) + O_2(g) \longrightarrow 2\,Na_2O(s)$;
(b) $6\,Li(s) + N_2(g) \xrightarrow{\Delta} 2\,Li_3N(s)$;
(c) $2\,Na(s) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g)$;
(d) $4\,KO_2(s) + 2\,H_2O(g) \longrightarrow 4\,KOH(s) + 3\,O_2(g)$

15.29 $Mg(s) + 2\,H_2O(l) \longrightarrow Mg(OH)_2 + H_2(g)$

15.31 (a) $CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s)$; (b) $-57.33\ kJ{\cdot}mol^{-1}$

15.33 (a) $Mg(OH)_2(s) + 2\,HCl(aq) \longrightarrow MgCl_2(aq) + 2\,H_2O(l)$;
(b) $Ca(s) + 2\,H_2O(l) \longrightarrow Ca(OH)_2(aq) + H_2(g)$;
(c) $BaCO_3(s) \xrightarrow{\Delta} BaO(s) + CO_2(g)$

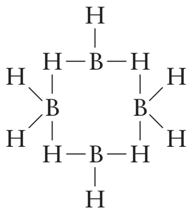
15.35 (a) $:\ddot{\underset{..}{Cl}}-Be-\ddot{\underset{..}{Cl}}:\qquad Mg^{2+}\quad 2\left[:\ddot{\underset{..}{Cl}}:\right]^-$;

$MgCl_2$ is ionic; $BeCl_2$ is a molecular compound. (b) 180° (c) sp

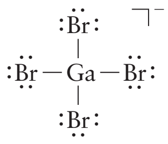
15.37 $4\,Al^{3+}(melt) + 6\,O^{2-}(melt) + 3\,C(s, gr) \longrightarrow 4\,Al(s) + 3\,CO_2(g)$

15.39 (a) $B_2O_3(s) + 3\,Mg(l) \xrightarrow{\Delta} 2\,B(s) + 3\,MgO(s)$;
(b) $2\,Al(s) + 3\,Cl_2(g) \longrightarrow 2\,AlCl_3(s)$; (c) $4\,Al(s) + 3\,O_2(g) \longrightarrow 2\,Al_2O_3(s)$

15.41 Bridging H atoms and four-coordinate B atoms have formal charge of −1; terminal H atoms and three-coordinate B atoms have formal charge of 0.



15.43 The shape of $GaBr_4^-$ is tetrahedral.



15.45 Silicon occurs widely in the Earth's crust in the form of silicates in rocks and as silicon dioxide in sand. It is obtained from quartzite, a form of quartz (SiO_2), by the following processes: (1) reduction in an electric arc furnace, $SiO_2(s) + 2\,C(s) \longrightarrow Si(s, crude) + 2\,CO(g)$. (2) Purification of the crude product in two steps, $Si(s, crude) + 2\,Cl_2(g) \longrightarrow SiCl_4(l)$, followed by reduction with hydrogen to the pure element, $SiCl_4(l) + 2\,H_2(g) \longrightarrow Si(s, pure) + 4\,HCl(g)$.

15.47 (a) +4; (b) +4; (c) +4

15.49 (a) $MgC_2(s) + 2\,H_2O(l) \longrightarrow C_2H_2(g) + Mg(OH)_2(s)$ (acid–base);
(b) $2\,Pb(NO_3)_2(s) \longrightarrow 2\,PbO(s) + 4\,NO_2(g) + O_2(g)$ (redox)

15.51 $\Delta H_r° = 689.88\ kJ{\cdot}mol^{-1}$; $\Delta S_r° = 360.85\ J{\cdot}K^{-1}{\cdot}mol^{-1}$; $\Delta G_r° = 582.29\ kJ{\cdot}mol^{-1}$; 1912 K

15.53 −3: NH_3, Li_3N, $LiNH_2$, NH_2^-; −2: H_2NNH_2; −1: N_2H_2, NH_2OH; 0: N_2; +1: N_2O, N_2F_2; +2: NO; +3: NF_3, NO_2^-; NO^+; +4: NO_2, N_2O_4; +5: HNO_3, NO_3^-; NO_2F

15.55 $CO(NH_2)_2(aq) + 2\,H_2O(l) \longrightarrow (NH_4)_2CO_3(aq)$; 6.4 kg

15.57 (a) 0.35 L. (b) larger volume. (c) Metal azides are good explosives because the azide ion is thermodynamically unstable with respect to the production of $N_2(g)$. This is because the N≡N triple bond is so strong and also because the production of a gas is favored entropically.

15.59 N_2O: $H_2N_2O_2$; $N_2O(g) + H_2O(l) \longrightarrow H_2N_2O_2(aq)$
N_2O_3: HNO_2; $N_2O_3(g) + H_2O(l) \longrightarrow 2\,HNO_2(aq)$
N_2O_5: HNO_3; $N_2O_5(g) + H_2O(l) \longrightarrow 2\,HNO_3(aq)$

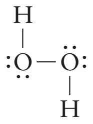
15.61 Ammonia (NH_3) can undergo hydrogen bonding with itself while NF_3 cannot.

15.63 (a) $4\,Li(s) + O_2(g) \xrightarrow{\Delta} 2\,Li_2O(s)$;
(b) $2\,Na(s) + 2\,H_2O(l) \longrightarrow 2\,NaOH(aq) + H_2(g)$;
(c) $2\,F_2(g) + 2\,H_2O(l) \longrightarrow 4\,HF(aq) + O_2(g)$;
(d) $2\,H_2O(l) \longrightarrow O_2(g) + 4\,H^+(aq) + 4\,e^-$

15.65 (a) $2\,H_2S(g) + 3\,O_2(g) \xrightarrow{\Delta} 2\,SO_2(g) + 2\,H_2O(g)$;
(b) $CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq)$;
(c) $2\,H_2S(g) + SO_2(g) \xrightarrow{300°C, Al_2O_3} 3\,S(s) + 2\,H_2O(l)$

15.67 Both water and ammonia have four groups attached to their central atom and therefore both possess a tetrahedral electronic (or VSEPR) geometry. However, H_2O has two unshared electron pairs while NH_3 only has one, producing a larger dipole moment for H_2O.

15.69 (a)



The bond angle is predicted to be <109.5°. In actuality, it is 97°.
(b) Cu^+ and (c) Mn^{2+} will be oxidized.

15.71 13.11 (13.12 if K_{a2} is not ignored)

15.73 The weaker the H—X bond, the stronger the acid. H_2Te has the weakest bond; H_2O, the strongest. Therefore, the acid strengths are $H_2Te > H_2Se > H_2S > H_2O$.

15.75 (a) +1; (b) +4; (c) +7; (d) +5

15.77 (a) $4\,KClO_3(l) \xrightarrow{\Delta} 3\,KClO_4(s) + KCl(s)$.
(b) $Br_2(l) + H_2O(l) \longrightarrow HBrO(aq) + HBr(aq)$.
(c) $NaCl(s) + H_2SO_4(aq \longrightarrow NaHSO_4(aq) + HCl(g)$.
(d) (a) and (b) are redox reactions; (c) is a Brønsted acid–base reaction.

15.79 (a) $HClO < HClO_2 < HClO_3 < HClO_4$.
(b) The oxidation number of Cl increases from HClO to $HClO_4$. In $HClO_4$, chlorine has its highest oxidation number of +7, so $HClO_4$ will be the strongest oxidizing agent.

15.81 $:\ddot{\underset{..}{Cl}}-\ddot{\underset{..}{O}}-\ddot{\underset{..}{Cl}}:$, AX_2E_2, angular, about 109°. The actual bond angle is 110.9°.

15.83 (a) ICl_5 has too many highly electronegative chlorine atoms present on the central iodine. (b) IF_2 has an odd number of electrons and as a result is a radical and highly reactive. (c) $ClBr_3$ is sterically too crowded (too many large atoms on a small central atom).

15.85 (a) IF_3; (b) $3\,XeF_2(g) + I_2(g) \longrightarrow 2\,IF_3(s) + 3\,Xe(g)$

15.87 Because $E_{cell}°$ is negative, $Cl_2(g)$ will not oxidize Mn^{2+} to form the permanganate ion in an acidic solution.

15.89 $0.117\ mol{\cdot}L^{-1}$

15.91 7.59×10^3 kJ of heat is released.

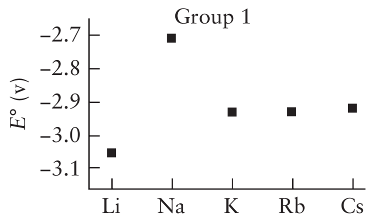
15.93 Helium occurs as a component of natural gases found under rock formations in certain locations, especially some in Texas. Argon is obtained by distillation of liquid air.

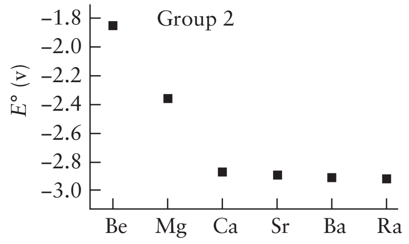
15.95 (a) +2; (b) +6; (c) +4; (d) +6

15.97 $XeF_4(aq) + 4\,H^+(aq) + 4\,e^- \longrightarrow Xe(g) + 4\,HF(aq)$

15.99 Because H_4XeO_6 has more highly electronegative O atoms bonded to Xe, we predict that H_4XeO_6 is more acidic than H_2XeO_4.

15.101 (a)





(b) For both groups, the trend in standard potentials with increasing atomic number is overall downward (they become more negative), but lithium is anomalous. This overall downward trend makes sense because we expect that it is easier to remove electrons that are farther away from the nuclei. However, because there are several factors that influence ease of removal, the trend is not smooth. The potentials are a net composite of the free energies of sublimation of solids, dissociation of gaseous molecules, ionization enthalpies, and enthalpies of hydration of gaseous ions. The origin of the anomalously strong reducing power of Li is the strongly exothermic energy of hydration of the very small Li^+ ion, which favors the ionization of the element in aqueous solution.

15.103 In the majority of its reactions, hydrogen acts as a reducing agent; that is, $H_2(g) \longrightarrow 2\,H^+(aq) + 2\,e^-$, $E° = 0$ V. In these reactions, hydrogen resembles Group 1 elements, such as Na and K. However, as described in the text, it may also act as an oxidizing agent; that is, $H_2(g) + 2\,e^- \longrightarrow 2H^-(aq)$, $E° = -2.25$ V. In these reactions, hydrogen resembles Group 17 elements, such as Cl and Br. Consequently, H_2 will oxidize elements with standard reduction potentials more negative than –2.25 V, such as the alkali and alkaline earth metals (except Be). The compounds formed are hydrides and contain the H^- ion; the singly charged negative ion is reminiscent of the halide ions. Hydrogen also forms diatomic molecules and covalent bonds like the halogens. The atomic radius of H is 78 pm, which compares rather well to that of F (64 pm) but not as well to that of Li (157 pm). The ionization energy of H is 1310 $kJ{\cdot}mol^{-1}$, which is similar to that of F (1680 $kJ{\cdot}mol^{-1}$) but not similar to that of Li (519 $kJ{\cdot}mol^{-1}$). The electron affinity of H is +73 $kJ{\cdot}mol^{-1}$, that of F is +328 $kJ{\cdot}mol^{-1}$, and that of Li is 60 $kJ{\cdot}mol^{-1}$. So in its atomic radius and ionization energy, H more closely resembles the Period 2 halogen, fluorine, in Group 17, than the Period 2 alkali metal, lithium, in Group 1; whereas in electron affinity, it more closely resembles lithium, Group 1. In electronegativity, H does not resemble elements in either Group 1 or Group 17, although its electronegativity is somewhat closer to those of Group 1. Consequently, hydrogen could be placed in either Group 1 or Group 17. But it is best to think of hydrogen as a unique element that has properties in common with both metals and nonmetals; therefore, it should probably be centered in the periodic table, as it is shown in the table in the text.

15.105 0.0538 $mol{\cdot}L^{-1}$

15.107 Gases (a), (b), (c), and (d) can all function as greenhouse gases, while (e) cannot; argon is monoatomic.

15.109 Octane contributes more CO_2 per liter burned. We also need to consider how much energy is produced per liter of fuel burned.

15.111 (a) Diborane, B_2H_6, and Al_2Cl_6(g) have the same basic structure in the way in which the atoms are arranged in space. (b) The bonding between the boron atoms and the bridging hydrogen atoms is electron deficient. There are three atoms and only two electrons to hold them together in a 3-center-2-electron bond. The bonding in Al_2Cl_6 is conventional in that all the bonds involve two atoms and two electrons. Here, the lone pair of a Cl atom is donated to an adjacent Al. (c) The hybridization is sp^3 at the B and Al atoms. (d) The molecules are not planar. The Group 13 element and the terminal atoms to which it is bound lie in a plane that is perpendicular to the plane that contains the main group element and the bridging atoms.

15.113 (a) Molecule (g) $\longrightarrow$ $Molecule^+(g) + e^-(g)$. (b) SiI_4 has more electrons than $SiCl_4$; I is also less electronegative and much bigger (and therefore more polarizable) than Cl. As a result it should be easier to remove an electron from SiI_4, meaning that $SiCl_4$ should have the higher ionization energy.

15.115 (a) 10-electron species: NH_3 and H_3O^+. 15-electron species: NO and O_2^+. 22-electron species: N_2O^+ and NO_2^+. (b) H_3O^+, NO, and NO_2^+. (c) NH_3, NO, and N_2O^+

15.117 Due to reduced hydrogen bonding, thiosulfuric acid should be less acidic and have a lower boiling point.

15.119 337.9 g

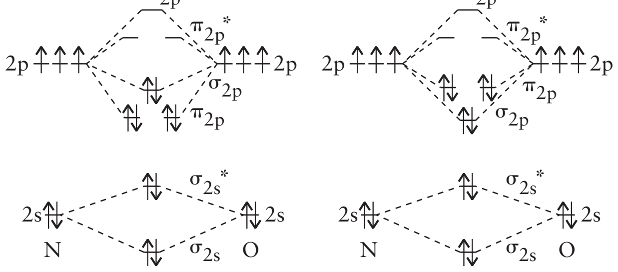
15.121 strongest: (a), ion–ion; weakest: (d) dipole–dipole

15.123 (a) $[:\ddot{N}=\ddot{N}=\ddot{N}:]^{-1}$, AX_2, linear 180°; (b) F^-, 133 pm; N_3^-, 148 pm; Cl^-, 181 pm; therefore, between fluorine and chlorine. (c) HCl, HBr, and HI are all strong acids. For HF, $K_a = 3.5 \times 10^{-4}$, so HF is slightly more acidic than HN_3. The small size of the azide ion suggests that the H—N bond in HN_3 is similar in strength to that of the H—F bond, so it is expected to be a weak acid. (d) ionic: NaN_3, $Pb(N_3)_2$, AgN_3, etc.; covalent: HN_3, $B(N_3)_3$, FN_3, etc.

15.125 The solubility of the ionic halides is determined by a variety of factors, especially the lattice enthalpy and enthalpy of hydration. There is a delicate balance between the two factors, with the lattice enthalpy usually being the determining one. Lattice enthalpies decrease from chloride to iodide, so water molecules can more readily separate the ions in the latter. Less ionic halides, such as the silver halides, generally have a much lower solubility, and the trend in solubility is the reverse of the more ionic halides. For the less ionic halides, the covalent character of the bond allows the ion pairs to persist in water. The ions are not easily hydrated, making them less soluble. The polarizability of the halide ions, and thus the covalency of their bonding, increases down the group.

15.127 (a) The molecular orbital diagram for NO^+ should have the oxygen orbitals slightly lower in energy than the nitrogen orbitals, because oxygen is more electronegative. This will cause the bonding to be more ionic than in either N_2 or O_2. There is an ambiguity, however, in that the MO diagram could be similar to either that of N_2 or that of O_2.

Refer to Figures 3.31 and 3.32, where you will see that the σ_{2p} and π_{2p} have different relative energies. There are consequently two possibilities for the orbital energy diagram:



NO^+ (using N MO diagram) NO^+ (using O MO diagram)

(b) The two orbital diagrams predict the same bond order (3) and same magnetic properties (diamagnetic), and so these properties cannot be used to determine which diagram is the correct one. That must be determined by more complex spectroscopic measurements.

15.129 (a) cloud: [NO] = 860 ppt and $[NO_2]$ = 250 ppt; clear air: [NO] = 480 ppt and $[NO_2]$ = 260 ppt. (b) clouds. (c) In addition to jet engines and automobile emissions, NO is also formed when NO_2 dissolves in water. As a result one would expect to find more NO and less NO_2 in clouds, which also contain water vapor. (d) nitrous acid: $\ddot{\underset{\cdot\cdot}{O}}=\underset{\cdot\cdot}{N}-\ddot{\underset{\cdot\cdot}{O}}-H$. (e) Nitrous acid would be expected to be more stable than either NO or the hydroxyl radical since both of these species have unpaired electrons while nitrous acid does not. (f) A possible mechanism that fits the observed rate law would be
Step 1: $NO + O_3 \longrightarrow NO_2 + O_2$ (slow)
Step 2: $NO_2 + O \longrightarrow NO + O_2$ (fast)
(g) 7.56×10^{-29} molecules·cm^{-3}·sec^{-1}

Chapter 16

16.1 Elements at the left of the d-block tend to have strongly negative standard potentials.
16.3 (a) Ti. (b) Because of the lanthanide contraction, they are about the same size. (c) Ta. (d) Ir
16.5 (a) Fe; (b) Cu; (c) Pt; (d) Pd; (e) Ta
16.7 Hg is much more dense than Cd, because the shrinkage in atomic radius that occurs between $Z = 58$ and $Z = 71$ (the lanthanide contraction) causes the atoms following the rare earths to be smaller than might have been expected for their atomic masses and atomic numbers. Zn and Cd have densities that are not too dissimilar, because the radius of Cd is subject only to a smaller d-block contraction.
16.9 (a) Proceeding down a group in the d-block (for example, from Cr to Mo to W), there is an increasing probability of finding the elements in higher oxidation states. That is, higher oxidation states become more stable on going down a group. (b) The trend for the p-block elements is reversed. Because of the inert-pair effect, the higher oxidation states tend to be less stable as one descends a group.
16.11 The +6 oxidation state is most stable for Cr.
16.13 (a) $TiCl_4(g) + 2Mg(l) \xrightarrow{\Delta} Ti(s) + 2\,MgCl_2(s)$;
(b) $CoCO_3(s) + HNO_3(aq) \longrightarrow Co^{2+}(aq) + HCO_3^-(aq) + NO_3^-(aq)$;
(c) $V_2O_5(s) + 5\,Ca(l) \xrightarrow{\Delta} 2\,V(s) + 5\,CaO(s)$
16.15 (a) titanium(IV) oxide, TiO_2; (b) iron(III) oxide, Fe_2O_3; (c) managanese(IV) oxide, MnO_2; (d) iron(II) chromite, $FeCr_2O_4$
16.17 (a) CO (b) In Zones D & C, $3\,Fe_2O_3(s) + CO(g) \longrightarrow$

$2\,Fe_3O_4(s) + CO_2(g)$, $Fe_3O_4(s) + CO(g) \longrightarrow 3\,FeO(s) + CO_2(g)$.

These reactions combine to give $Fe_2O_3(s) + CO(g) \longrightarrow$

$2\,FeO(s) + CO_2(g)$. In Zone B, $Fe_2O_3(s) + 3\,CO(g) \longrightarrow$

$2\,Fe(s) + 3\,CO_2(g)$, $FeO(s) + CO(g) \longrightarrow Fe(s) + CO_2(g)$.
(c) carbon
16.19 (a) yes; (b) no
16.21 (a) $V_2O_5(s) + 2\,H_3O^+(aq) \longrightarrow 2\,VO_2^+(aq) + 3H_2O(l)$;
(b) $V_2O_5(s) + 6\,OH^-(aq) \longrightarrow 2\,VO_4^{3-}(aq) + 3\,H_2O(l)$
16.23 As the value of n increases, d- and f-electrons become less effective at shielding the outermost, highest energy electron(s) from the attractive charge of the nucleus. This higher effective nuclear charge makes it more difficult to oxidize the metal atom or ion.
16.25 (a) $[Cr(OH_2)_6]^{3+}(aq)$, behaves as a Brønsted acid:
$[Cr(OH_2)_6]^{3+}(aq) + H_2O(l) \longrightarrow [Cr(OH_2)_5OH]^{2+}(aq) + H_3O^+(aq)$.
(b) The gelatinous precipitate is the hydroxide $Cr(OH)_3$. The precipitate dissolves as the $Cr(OH)_4^-$ complex ion is formed: $Cr^{3+}(aq) +$
$3\,OH^-(aq) \longrightarrow Cr(OH)_3(s)$, $Cr(OH)_3(s) + OH^-(aq) \longrightarrow Cr(OH)_4^-(aq)$.
16.27 (a) hexacyanoferrate(II) ion, +2; (b) hexaamminecobalt(III) ion, +3; (c) aquapentacyanocobaltate(III) ion, +3; (d) pentaamminesulfatocobalt(III) ion, +3
16.29 (a) $K_3[Cr(CN)_6]$; (b) $[Co(NH_3)_5(SO_4)]Cl$;
(c) $[Co(NH_3)_4(OH_2)_2]Br_3$; (d) $Na[Fe(OH_2)_2(C_2O_4)_2]$
16.31 (a) 3; (b) 1 or 2; (c) monodenate, 1; (d) 2
16.33 Only (b); in (a) and (c), the amine groups are too far apart to coordinate to the same metal atom.
16.35 (a) 4; (b) 2; (c) 6 (en is bidentate); (d) 6 (EDTA is hexadentate)

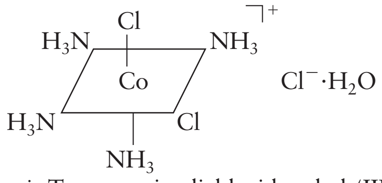
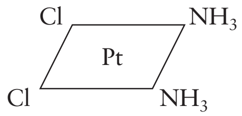
and



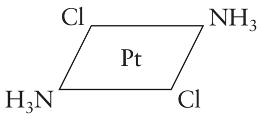
cis-Tetraamminedichloridocobalt(III) chloride monohydrate

(b) no; (c) yes



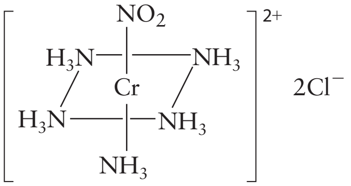
cis-Diamminedichloridoplatinum(II)

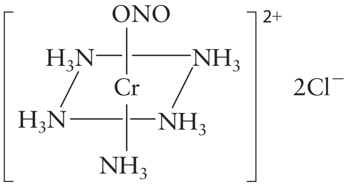
and

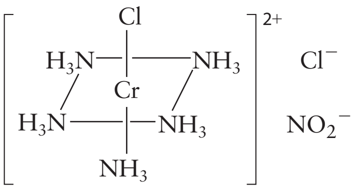


trans-Diamminedichloridoplatinum(II)

16.41 two linkage isomers, one ionization isomer:



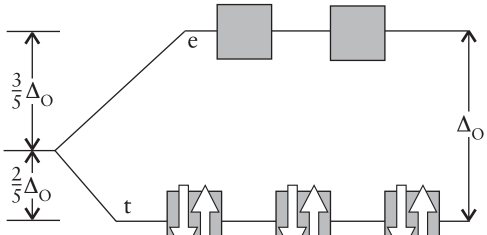




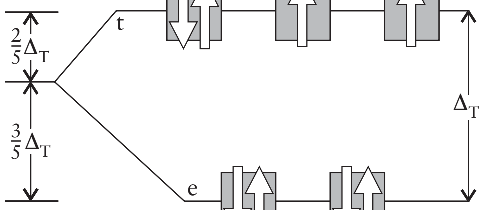
16.43 (a) chiral; (b) not chiral

16.45 (a) 2; (b) 5; (c) 8; (d) 10; (e) 0 (or 8); (f) 10

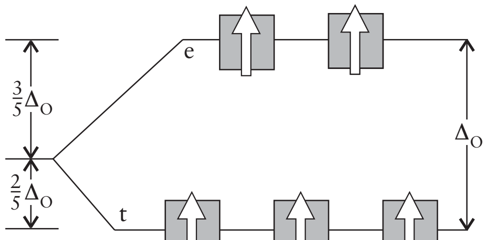
16.47 (a) octahedral; strong-field ligand, 6 e^-, no unpaired electrons



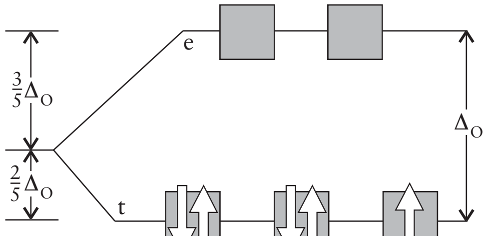
(b) tetrahedral: weak-field ligand, 8 e^-, two unpaired electrons



(c) octahedral: weak-field ligand, 5 e^-, five unpaired electrons



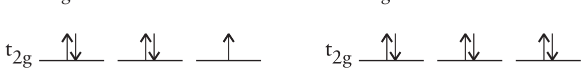
(d) octahedral: strong-field ligand, 5 e^-, one unpaired electron



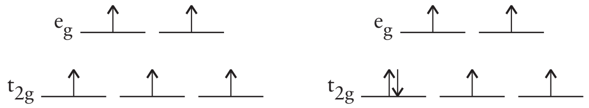
16.49 (a) 0; (b) 2

16.51 Weak-field ligands do not interact strongly with the d-electrons in the metal ion, so they produce only a small crystal field splitting of the d-electron energy states. The opposite is true of strong-field ligands. With weak-field ligands, unpaired electrons remain unpaired if there are unfilled orbitals; hence, a weak-field ligand is likely to lead to a high-spin complex. Strong-field ligands cause electrons to pair up with electrons in lower energy orbitals. A strong-field ligand is likely to lead to a low-spin complex. Ligands arranged in the spectrochemical series help to distinguish strong-field and weak-field ligands. Measurement of magnetic susceptibility (paramagnetism) can be used to determine the number of unpaired electrons, which, in turn, establishes whether the associated ligand is weak-field or strong-field in nature.

16.53 In both cases we are looking at the difference between an $Fe^{3+}(d^5)$ and an $Fe^{2+}(d^6)$. Since CN^- is a strong-field ligand, we expect that all the d-electrons in the $[Fe(CN)_6]^{3-}$ complex are in the lower energy t_{2g} orbitals. Upon reduction, one more electron is added, resulting in all electrons being paired, giving a diamagnetic complex:



On the other hand, Cl^- is a weak-field ligand; here we expect the d-electrons to be distributed in both the t_{2g} and the e_g orbitals. Upon reduction, one more electron is added, resulting in only one electron being paired, leading to a complex that is still paramagnetic:



16.55 (a) $[CoF_6]^{3-}$ is blue because F^- is a weak-field ligand.
(b) $[Co(en)_3]^{3+}$ is yellow because the en ligand is a strong-field ligand.

16.57 573 nm, yellow

16.59 (a) 0; (b) longer

16.61 In Zn^{2+}, the 3d-orbitals are filled (d^{10}). Therefore, there can be no electronic transitions between the t- and e-levels; hence, no visible light is absorbed and the aqueous ion is colorless. The d^{10} configuration has no unpaired electrons, so Zn compounds would be diamagnetic, not paramagnetic.

16.63 (a) 162 $kJ \cdot mol^{-1}$; (b) 260 $kJ \cdot mol^{-1}$; (c) 208 $kJ \cdot mol^{-1}$;
(d) $Cl^- < H_2O < NH_3$

16.65 The e_g set, which comprises the $d_{x^2-y^2}$ and d_{z^2} orbitals.

16.67 (a) The CN^- ion is a π-acid ligand accepting electrons into the empty π^* orbital created by the C—N multiple bond. (b) The Cl^- ion has extra lone pairs in addition to the one that is used to form the σ-bond to the metal, and so it can act as a π-base, donating electrons in a p-orbital to an empty d-orbital on the metal. (c) H_2O, like Cl^-, also has an "extra" lone pair of electrons that can be donated to a metal center, making it a weak π-base; (d) en is neither a π-acid nor a π-base, because it does not have any empty π-type antibonding orbitals nor does it have any extra lone pairs of electrons to donate.
(e) $Cl^- < H_2O < en < CN^-$. Note that the spectrochemical series orders the ligands as π-bases < σ-bond only ligands < π-acceptors.

16.69 nonbonding or slightly antibonding. In a complex that forms only σ-bonds, the t_{2g} set of orbitals is nonbonding. If the ligands can function as weak π-donors (those close to the middle of the spectrochemical series, such as H_2O), the t_{2g} set becomes slightly antibonding by interacting with the filled p-orbitals on the ligands.

16.71 Antibonding. The e_g set of orbitals on an octahedral metal ion are always antibonding because of interactions with ligand orbitals that form the σ-bonds. This is true regardless of whether the ligands are π-acceptors, π-donors, or neither.

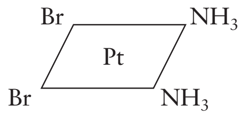
16.73 Water has two lone pairs of electrons. Once one of these is used to form the σ-bond to the metal ion, the second may be used to form a π-bond. This causes the t_{2g} set of orbitals to move up in energy, making Δ_O smaller; therefore, water is a weak-field ligand. Ammonia does not have this extra lone pair of electrons and consequently cannot function as a π-donor ligand.

16.75 The green color suggests chromium or copper but the blue solution formed when the mineral is dissolved in sulfuric acid points to copper as the metal ($CuSO_4$ is blue). The colorless gas that forms either upon heating or on treatment with acid is carbon dioxide; this is proven when the gas is bubbled into limewater (the cloudiness in the solution is due to calcium carbonate formation). CO_2 is formed when carbonates are either heated or treated with acid. The mineral is most likely basic copper carbonate ($Cu_2CO_3(OH)_2$).

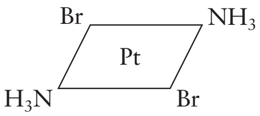
16.77 (a) +3; (b) $2\ V_2O_5(s) + 8\ C(s) \longrightarrow V_4C_3(s) + 5\ CO_2(g)$

16.79 3.6×10^{-31}

16.81 (a) $[PtBrCl(NH_3)_2]$



cis-Diamminedichloridoplatinum(II)

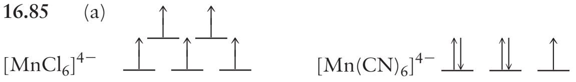


trans-Diamminedichloridoplatinum(II)

(b) If the compound were tetrahedral, there would be only one compound, not two.

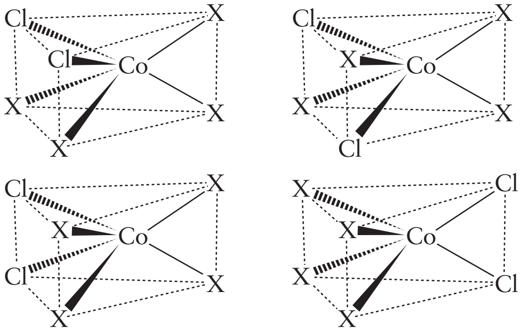
16.83 (a) The first, $[Ni(SO_4)(en)_2]Cl_2$, will give a precipitate of AgCl when $AgNO_3$ is added; the second will not. (b) The second, $[NiCl_2(en)_2]I_2$, will show free I_2 when mildly oxidized with, for example, Br_2, but the first will not.

16.85 (a)



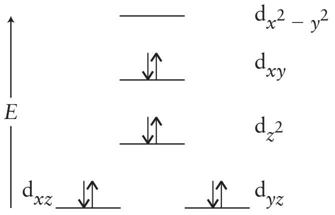
(b) $[MnCl_6]^{4-}$: five; $[Mn(CN)_6]^{4-}$: one. (c) Complexes with weak-field ligands absorb longer wavelength light; therefore, $[MnCl_6]^{4-}$ absorbs longer wavelengths.

16.87 If the prismatic structure were the true structural form of $[CoCl_2(NH_3)_4]$, one would expect to get four possible isomers, not the two seen (X = NH_3):



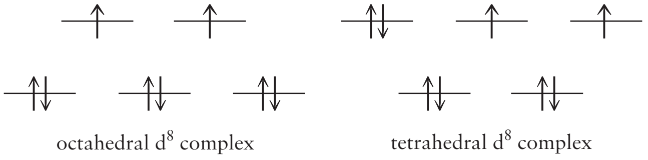
16.89 The correct structure for $[Co(NH_3)_6]Cl_3$ consists of four ions, $Co(NH_3)_6{}^{3+}$, and 3 Cl^- in aqueous solution. The chloride ions can be easily precipitated as AgCl. This would not be possible if they were bonded to the other (NH_3) ligands. If the structure were $Co(NH_3—NH_3—Cl)_3$, VSEPR theory would predict that the Co^{3+} ion would have a trigonal planar ligand arrangement. The splitting of the d-orbital energies would not be the same as the octahedral arrangement and would lead to different spectroscopic and magnetic properties inconsistent with the experimental evidence. In addition, neither optical nor geometrical isomers would be observed.

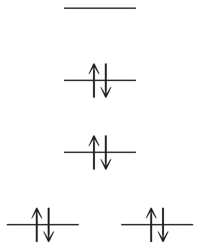
16.91 See Figure 16.26. Remove (mentally) the ligands along the ± *z* axes. From the shape of the atomic orbitals and their orientation with respect to the *x*, *y*, and *z* axes, it is clear that the $d_{x^2-y^2}$-orbital will have the greatest overlap, therefore repulsion, from the ligands in the *xy* plane. The d_{xy}-orbital will have the next strongest repulsion from these ligands, d_{z^2} next, and finally, the weakest repulsion will be with d_{xz} and d_{yz}. Therefore, the energy-level diagram will be (schematically):



The building-up principle is illustrated in the diagram with a d^8 ion (Pd^{2+}). The separation in energy between the $d_{x^2-y^2}$ and d_{xy} orbitals determines whether or not there will be unpaired electrons.

16.93 The electron configuration expected for Ni^{2+} is $[Ar]3d^8$. For this complex to have no unpaired electrons, it would have to be square planar in its electronic geometry, as both the octahedral and tetrahedral geometries require a d^8 species to have two unpaired electrons. Square planar does not:





square planar d^8 complex

16.95 Since NH_3 is a strong-field ligand (large Δ_O) and water is a weak-field ligand (small Δ_O), of the octahedral cobalt(II) complexes, $[Co(NH_3)_6]^{2+}$and $[Co(OH_2)_6]^{2+}$, it is expected that the hexaammine complex will absorb at a shorter wavelength and therefore transmit light of a higher wavelength than the hexaaquo complex. $[CoCl_4]^{2-}$ is a tetrahedral complex, and since the magnitude of Δ_t is much smaller than Δ_O it is expected this complex will absorb at the longest wavelength of the three and therefore transmit light of the shortest wavelength. Based on this, $[Co(NH_3)_6]^{2+}$ is yellow, $[Co(OH_2)_6]^{2+}$ is pink, and $[CoCl_4]^{2-}$ is blue.

16.97 (a) $[Co(NH_3)_5OH_2]Cl_3$, pentaammineaquacobalt(III) chloride, (b) $[CoCl(NH_3)_5]Cl_2$, pentaamminechloridocobalt (III) chloride

16.99 (a) trigonal bipyramidal. (b) +1. (c) There are six possible isomers

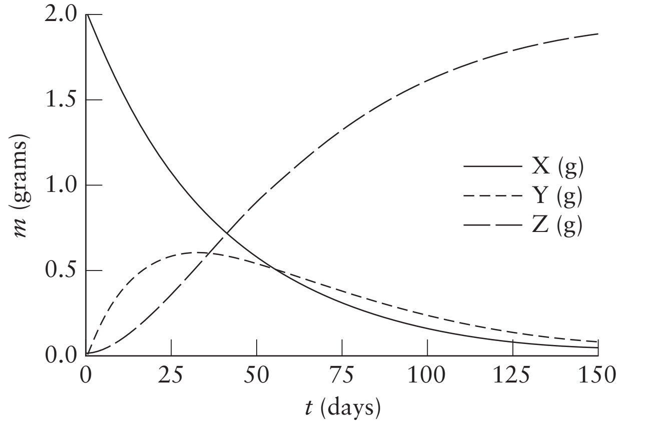
17.51 $[\text{X}] = [\text{X}]_0 e^{-k_1 t}$, $[\text{Y}] = \dfrac{k_1}{k_2 - k_1}(e^{-k_1 t} - e^{-k_2 t})[\text{X}]_0$,

$$[\text{Z}] = [\text{X}]_0 - \left([\text{X}]_0 e^{-k_1 t} + \frac{k_1}{k_2 - k_1}(e^{-k_1 t} - e^{-k_2 t})[\text{X}]_0\right)$$

$$= [\text{X}]_0\left(1 + \frac{k_1 e^{-k_2 t} - k_2 e^{-k_1 t}}{k_2 - k_1}\right),\ k_1 = 0.0253\ \text{d}^{-1},\ k_2 = 0.0371\ \text{d}^{-1}.$$

The plot assumes $[\text{X}]_0 = 2.00$ g.



17.53 If $H_2{}^{18}O$ is used in the reaction, the label can be followed. Once the products are separated, a suitable technique, such as vibrational spectroscopy or mass spectrometry, can be used to determine whether the product has incorporated the ^{18}O. For example, if the methanol ends up with the O atom from the water molecules, then its molar mass would be 34 g·mol^{-1}, rather than the 32 g·mol^{-1} found for methanol with elements present at their natural isotopic abundance.

17.55 The vibrational frequency will decrease.

(b) Tc-99m (N/Z = 1.30 versus 1.36 for Mo-99)

17.85 To make a small nuclear bomb you need what is called a "critical mass" of radioactive material; this is the minimum amount of material needed to achieve spontaneous fission, which is the process that causes the bomb to explode. For plutonium, the amount of material needed is about 17 kg (or 33 lb), the weight of an average three-year-old child. Plutonium, however, is very dense (a large amount of it can fit in a very small space), so the actual *size* of this amount of plutonium would only be the size of a grapefruit, or just a little bigger than a softball.

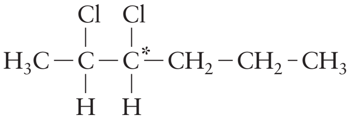
(d) optically active,



18.29 The difference can be traced to the weaker London forces that exist in branched molecules. Atoms in neighboring branched molecules cannot lie as close together as they can in unbranched isomers.

18.31 The balanced equations are $C_3H_8(g) + 5\ O_2(g) \longrightarrow 3\ CO_2(g) + 4\ H_2O(l)$, $C_4H_{10}(g) + \frac{13}{2}\ O_2(g) \longrightarrow 4\ CO_2(g) + 5\ H_2O(l)$, $C_5H_{12}(g) + 8\ O_2(g) \longrightarrow 5\ CO_2(g) + 6\ H_2O(l)$. The enthalpies of combustion that correspond to these reactions are listed in Appendix 2:

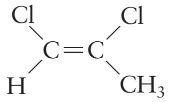
Compound	(a) Enthalpy of combustion ($kJ \cdot mol^{-1}$)	(b) Heat released per g ($kJ \cdot g^{-1}$)
propane	−2220	50.3
butane	−2878	49.5
pentane	−3537	49.0

The molar enthalpy of combustion increases with molar mass as might be expected, because the number of moles of CO_2 and H_2O formed will increase as the number of carbon and hydrogen atoms in the compounds increases. The heat released per gram of these hydrocarbons is essentially the same because the H to C ratio is similar in the three hydrocarbons.

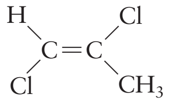
18.33 nine, none

18.35 (a) 4 σ-type single bonds; (b) 2 σ-type single bonds and 1 double bond with a σ-bond and a π-bond; (c) 1 σ-type single bond and 1 triple bond with a σ-bond and 2 π-bonds

18.37



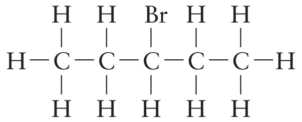
cis-1,2-Dichloropropene



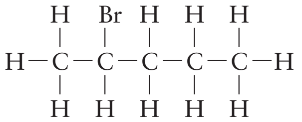
trans-1,2-Dichloropropene

cis-1,2-Dichloropropene is polar, although *trans*-1,2-dichloropropene is slightly polar also.

18.39 (a)



3-Bromopentane

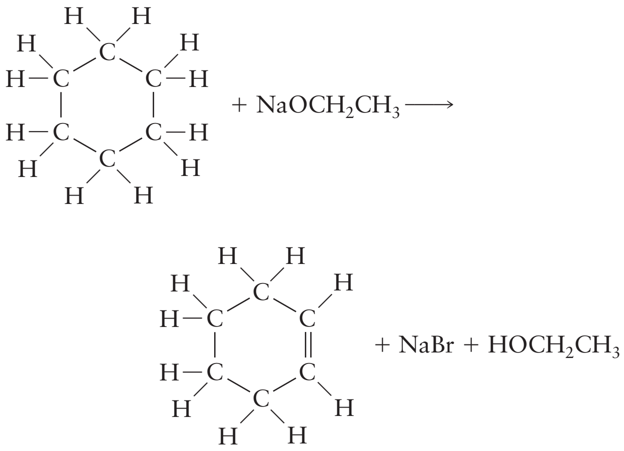


2-Bromopentane

(b) addition reaction

18.41 (a) $C_6H_{11}Br + NaOCH_2CH_3 \longrightarrow C_6H_{10} + NaBr + HOCH_2CH_3$

(b)

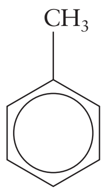


(c) elimination reaction

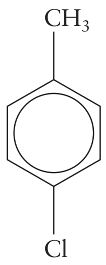
18.43 The reaction is less exothermic as the halogen becomes heavier. In general, the reactivity, and also the danger associated with use of the halogens in reactions, decreases as one descends the periodic table.

18.45 (a) 1-ethyl-3-methylbenzene; (b) pentamethylbenzene (1,2,3,4,5-pentamethylbenzene is also correct, but, because there is only one possible pentamethylbenzene, the use of the numbers is not necessary)

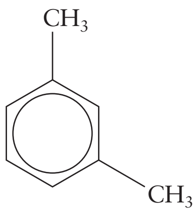
18.47 (a)



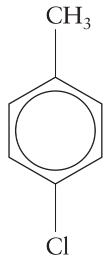
(b)



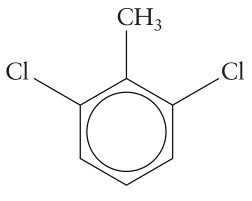
(c)



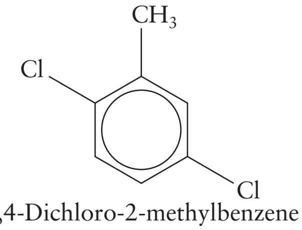
(d)



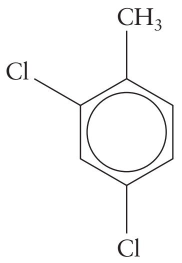
18.49 (a)



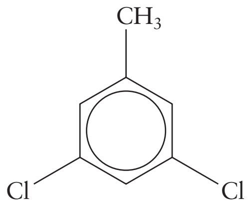
1,3-Dichloro-2-methylbenzene



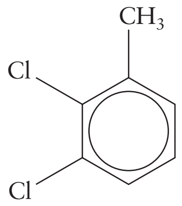
1,4-Dichloro-2-methylbenzene



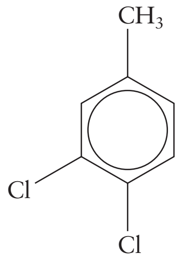
1,5-Dichloro-2-methylbenzene



1,3-Dichloro-5-methylbenzene



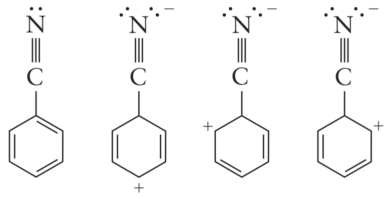
1,2-Dichloro-3-methylbenzene



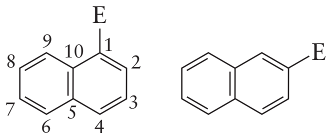
1,2-Dichloro-4-methylbenzene

(b) All of these molecules are at least slightly polar.

18.51

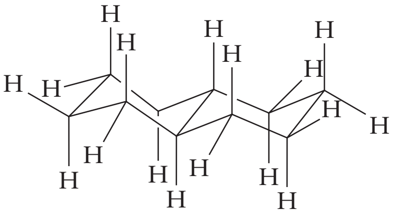


18.53 Two compounds can be produced. Resonance makes positions 1, 4, 6, and 9 equivalent. It also makes positions 2, 3, 7, and 8 equivalent. Positions 5 and 10 are equivalent but have no H atom.

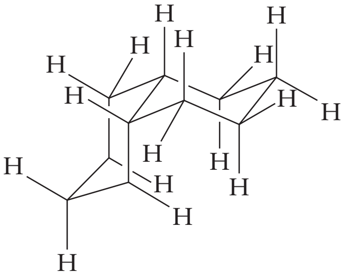


18.55 These hydrocarbons are too volatile (they are all gases at room temperature) and would not remain in the liquid state.
18.57 $CH_2CHCH_3 + CH_3CH_2CH_2CH_3 \longrightarrow CH_3(CH_2)_5CH_3$
18.59 (a) substitution, $CH_4 + Cl_2 \longrightarrow CH_3Cl + HCl$; (b) addition $CH_2{=}CH_2 + Br_2 \longrightarrow CH_2Br{-}CH_2Br$
18.61 Water is not used, as the nonpolar reactants will not readily dissolve in a highly polar solvent like water. Also, the ethoxide ion reacts with water.
18.63 (a) $CH_3CH_2CH_3(g) + 5\ O_2(g) \longrightarrow 3\ CO_2(g) + 4\ H_2O(g)$; $CHCH + 2\frac{1}{2}\ O_2(g) \longrightarrow 2\ CO_2(g) + H_2O(g)$. (b) propane: $-46.35\ kJ{\cdot}g^{-1}$; ethyne: $-48.22\ kJ{\cdot}g^{-1}$. (c) More heat is released per gram of ethyne, resulting in a hotter flame.
18.65 (a) 2-methyl-1-propene, no geometrical isomers; (b) *cis*-3-methyl-2-pentene, *trans*-3-methyl-2-pentene; (c) 1-hexyne, no geometrical isomers; (d) 3-hexyne, no geometrical isomers; (e) 2-hexyne, no geometrical isomers

18.67 (a) $C_{10}H_{18}$. (b) naphthalene, . $C_{10}H_8$. (c) yes. Cis and trans forms (relative to the C—C bond common to the two six-membered rings) are possible.

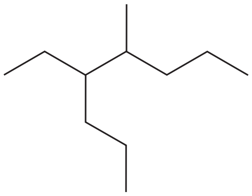


trans-Decalin



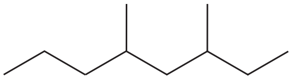
cis-Decalin

18.69 (a) 60°. (b) severe bond angle strain. (c) $-1488\ kJ{\cdot}mol^{-1}$. (d) Cyclopropane releases more heat on combustion because it is not a stable molecule due to severe bond angle strain. The C—C and C—H bonds in cyclopropane are not as stable as regular C—C and C–H bonds and their true bond enthalpies are lower values.
18.71 The empirical formula is C_4H_9; the molecular formula might be C_8H_{18}, which matches the formula for alkanes (C_nH_{2n+2}). It is not likely an alkene or alkyne, because there is no reasonable Lewis structure for a compound having the empirical formula C_4H_9 and multiple bonds.
18.73 (a)



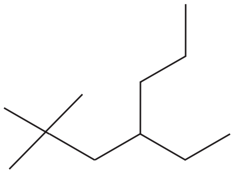
4-Ethyl-5-methyloctane

(b)



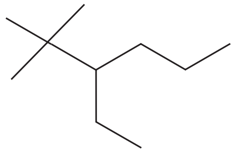
3,5-Dimethyloctane

(c)



2,2-Dimethyl-4-ethylheptane

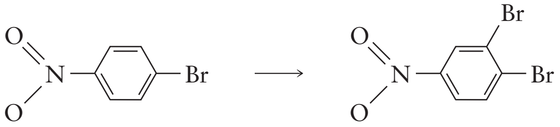
(d)



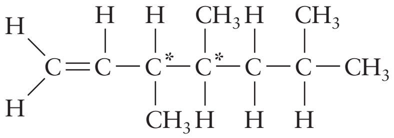
3-Ethyl-2,2-dimethylhexane

18.75 cyclopropane

18.77 The NO_2 group is a meta-directing group and the Br atom is an ortho, para-directing group. Because the position para to Br is already substituted with the NO_2 group, further bromination will not occur there. The resonance forms show that the bromine atom will activate the position ortho to it as expected. The NO_2 group will deactivate the group ortho to itself, thus in essence enhancing the reactivity of the position meta to the NO_2 group. This position is ortho to the Br atom, so the effects of the Br and NO_2 groups reinforce each other. Bromination is thus expected to occur as shown:



18.79 (a) and (b)



(c) no

18.81 For a molecule such as 1,2-dichloro-4-diethylbenzene, $C_6H_3Cl_2(CH_2CH_3)$, 175.04 m_u, it is relatively easy to lose heavy atoms such as chlorine and groups of atoms such as methyl and ethyl fragments. Molecules can also lose hydrogen atoms. In mass spectrometry, *P* is used to represent the *parent ion*, which is the ion formed from the molecule without fragmentation. Fragments are then represented as $P - x$, where x is the particular fragment lost from the parent ion to give the observed mass. Because the mass spectrum will measure the masses of individual molecules, the mass of carbon used will be 12.00 m_u (by definition) because the large majority of the molecules will have all ^{12}C. The mass of H is 1.0078 m_u. Some representative peaks that may be present are listed below.

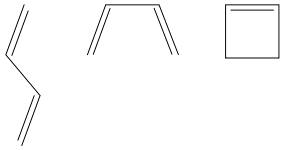
Fragment formula	Relation to parent ion	Mass (m_u)
$C_6H_3{}^{35}Cl_2(CH_2CH_3)$	P	174.00
$C_6H_3{}^{35}Cl^{37}Cl(CH_2CH_3)$	P	176.00
$C_6H_3{}^{37}Cl_2(CH_2CH_3)$	P	177.99
$C_6H_3{}^{35}Cl(CH_2CH_3)$	$P - Cl$	139.03
$C_6H_3{}^{37}Cl(CH_2CH_3)$	$P - Cl$	141.03
$C_6H_3{}^{35}Cl_2(CH_2)$	$P - CH_3$	158.98
$C_6H_3{}^{35}Cl^{37}Cl(CH_2)$	$P - CH_3$	160.97
$C_6H_3{}^{37}Cl_2(CH_2)$	$P - CH_3$	162.97
$C_6H_3{}^{35}Cl_2$	$P - CH_2CH_3$	144.96
$C_6H_3{}^{35}Cl^{37}Cl$	$P - CH_2CH_3$	146.96
$C_6H_3{}^{37}Cl_2$	$P - CH_2CH_3$	148.96
$C_6H_3{}^{35}Cl$	$P - CH_2CH_3{-}Cl$	109.99
$C_6H_3{}^{37}Cl$	$P - CH_2CH_3{-}Cl$	111.99
Etc.		

18.83 The presence of one bromine atom will produce in the ions that contain Br companion peaks that are separated by 2 m_u. Any fragment that contains Br will show this "doublet" in which the peaks are nearly but not exactly equal in intensity. Thus, seeing a mass spectrum of a compound that is known to have Br or that was involved in a reaction in which Br could have been added or substituted with such doublets, is almost a sure sign that Br is present in the compound. It is also fairly easy to detect Br atoms in the mass spectrum at 79 and 81 m_u, confirming their presence. If more than one Br atom is present, then a more complicated pattern is observed for the presence of the two isotopes. The possible combinations for a molecule of unknown formula with two Br atoms is $^{79}Br\ ^{79}Br$, $^{79}Br\ ^{81}Br$, $^{81}Br\ ^{79}Br$, and $^{81}Br\ ^{81}Br$. Thus, a set of three peaks (the two possibilities $^{79}Br\ ^{81}Br$ and $^{81}Br\ ^{79}Br$ have identical masses) will be generated that differ in mass by two units. The center peak, which is produced by the $^{79}Br\ ^{81}Br$ and $^{81}Br\ ^{79}Br$ combinations, will have twice the intensity of the outer two peaks, because statistically there are twice as many combinations that produce this mass. All modern mass spectrometers have spectral simulation programs that can readily calculate and print out the relative isotopic distribution pattern expected for any compound formulation, so that it is possible to easily match the expected pattern for a particular ion with the experimental result.

18.85 C_8H_{10} will have an absorption maximum at a longer wavelength. Molecular orbital theory predicts that in conjugated hydrocarbons (molecules which contain a chain of carbon atoms with alternating single and double bonds) electrons become delocalized and are free to move up and down the chain of carbon atoms. Such electrons may be described using the one-dimensional "particle-in-a-box" model introduced in Chapter 1. According to this model, as the box to which electrons are confined lengthens, the quantized energy states available to the electrons get closer together. As a result, the energy needed to excite an electron from the ground state to the next higher state is lower for electrons confined to longer boxes. Therefore, lower energy photons, i.e., photons with longer wavelengths, will be absorbed by the C_8H_{10} molecule because it provides a longer "box" than C_6H_8.

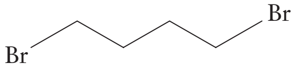
18.87 (a) C_2H_3; (b) C_4H_6

(c)

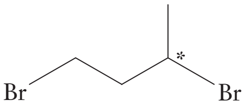


(d) the sixth compound (cyclobutene); (e) $C_4H_8Br_2$

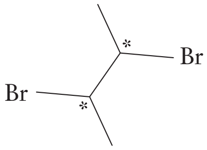
(f)



1,4-Dibromobutane



1,3-Dibromobutane



2,3-Dibromobutane

(g) All the carbons are sp^2 hybridized. (h) *trans*- and *cis*-1,3-butadiene.

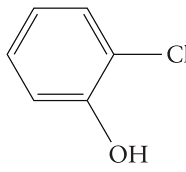
Chapter 19

19.1 (a) RNH_2, R_2NH, R_3N; (b) ROH; (c) RCOOH; (d) RCHO

19.3 (a) ether; (b) ketone; (c) amine; (d) ester

19.5 (a) 2-iodo-2-butene; (b) 2,4-dichloro-4-methylhexane; (c) 1,1,1,-triiodoethane; (d) dichloromethane

19.7 (a)



, $C_6H_4Cl(OH)$ phenol;

(b) $CH_3CH(CH_3)CH(OH)CH_2CH_3$, secondary alcohol;
(c) $CH_3CH_2CH(CH_3)CH_2CH(CH_3)CH_2OH$, primary alcohol;
(d) $CH_3C(CH_3)(OH)CH_2CH_3$, tertiary alcohol

19.9 (a) $CH_3CH_2OCH_3$; (b) $CH_3CH_2OCH_2CH_2CH_3$; (c) CH_3OCH_3

19.11 (a) butyl propyl ether; (b) methyl phenyl ether; (c) pentyl propyl ether

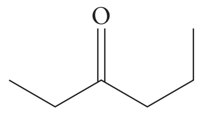
19.13 (a) aldehyde, ethanal; (b) ketone, propanone; (c) ketone, 3-pentanone

19.15

(a)

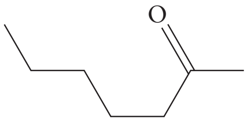
Butanal

(b)



3-Hexanone

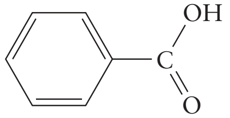
(c)



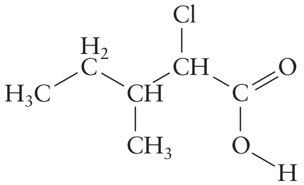
2-Heptanone

19.17 (a) ethanoic acid; (b) butanoic acid; (c) 2-aminoethanoic acid

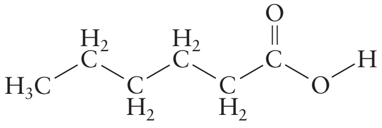
19.19 (a)



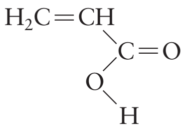
(b)



(c)

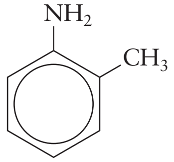


(d)

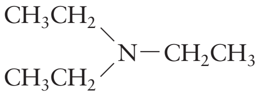


19.21 (a) methylamine; (b) diethylamine; (c) *o*-methylaniline, 2-methylaniline, *o*-methylphenylamine, or 1-amino-2-methylbenzene

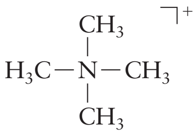
19.23 (a)



(b)



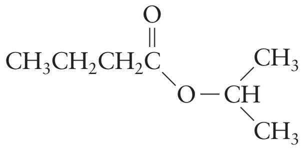
(c)



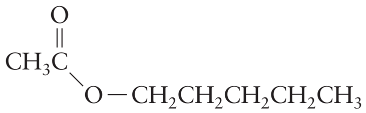
19.25 (a) and (c)

19.27 (a) ethanol. (b) 2-octanol. (c) 5-methyl-1-octanol. These reactions can be accomplished with an oxidizing agent such as acidified sodium dichromate, $Na_2Cr_2O_7$.

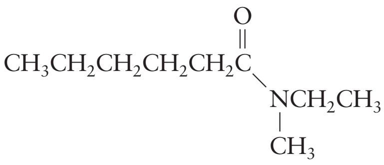
19.29 (a)



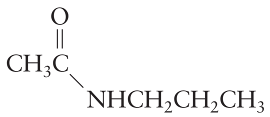
(b)



(c)



(d)



19.31 (a) addition; (b) condensation; (c) addition; (d) addition; (e) condensation

19.33 The following procedures can be used:

(1) Dissolve the compounds in water and use an acid–base indicator to look for a color change.

(2) $CH_3CH_2CHO \xrightarrow{\text{Tollens reagent}} CH_3CH_2COOH + Ag(s)$

(3) $CH_3COCH_3 \xrightarrow{\text{Tollens reagent}}$ no reaction

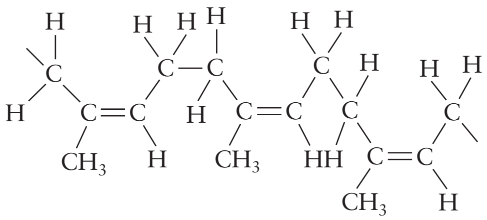
Procedure (1) will distinguish ethanoic acid; (2) and (3) will distinguish propanal from 2-propanone.

19.35 $CH_3CH_2COOH < CH_3COOH < ClCH_2COOH < Cl_3CCOOH$. The greater the electronegativities of the groups attached to the carboxyl group, the stronger the acid.

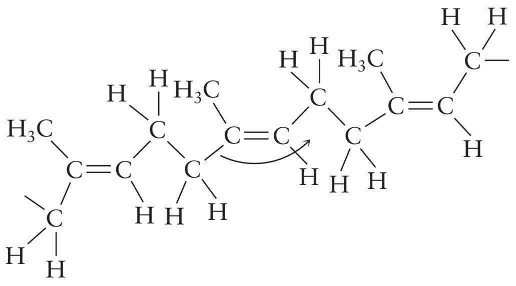
19.37 (a) $–CH_2–C(CH_3)_2–CH_2–C(CH_3)_2–CH_2–C(CH_3)_2–$

(b)

(c)



cis version



trans version

19.39 $HOOCC_6H_{12}COOH$; $NH_2C_6H_4NH_2$

19.41 (a) $CHCl{=}CH_2$; (b) $CFCl{=}CF_2$

19.43 (a) $–OCCONH(CH_2)_4NHCOCONH(CH_2)_4NH–$; (b) $–OC–CH(CH_3)–NH–OC–CH(CH_3)–NH–$

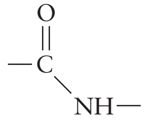
19.45 block copolymer

19.47 Polymers generally do not have definite molecular masses because there is no fixed point at which the chain-lengthening process will cease. The chain stops growing due to lack of nearby monomer units of the appropriate kind or a lack of properly oriented smaller polymeric aggregates. A polymer is, in a sense, not a pure compound, bur rather a mixture of similar compounds of different chain lengths. There is no fixed molar mass, only an average molar mass. Because there is no one unique compound, there is no one unique melting point, rather a range of melting points.

19.49 All increase with increasing molar mass.

19.51 Highly linear, unbranched chains allow for maximum interaction between chains. The greater the intermolecular contact between chains, the stronger the forces between them, and the greater the strength of the material.

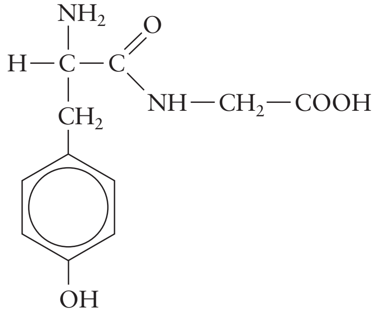
19.53 (a)



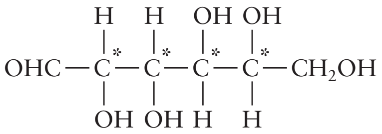
(b) amide; (c) condensation

19.55 Serine, threonine, tyrosine, aspartic acid, glutamic acid, lysine, arginine, histidine, asparagine, and glutamine satisfy the criteria. Proline and tryptophan generally do not contribute through hydrogen bonding, because they are typically found in hydrophobic regions of proteins.

19.57



19.59 (a) alcohols and aldehydes. (b) The chiral carbon atoms are marked with asterisks (*).

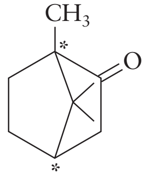


19.61 (a) GTACTCAAT; (b) ACTTAACGT

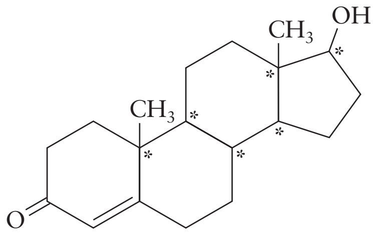
19.63 (a) $C_5H_5N_5O$; (b) $C_6H_{12}O_6$; (c) $C_3H_7NO_2$

19.65 (a) alcohol, ether, aldehyde; (b) ketone, alkene; (c) amine, amide

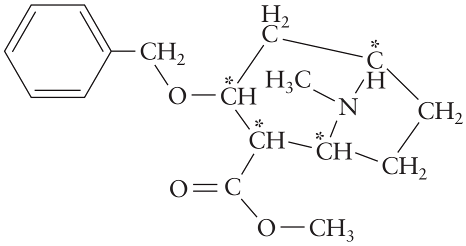
19.67 (a)



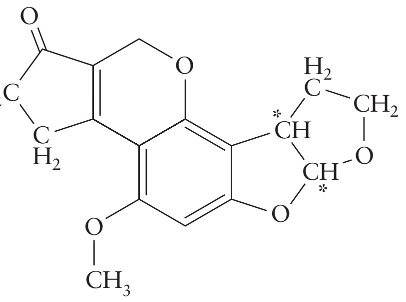
(b)



19.69

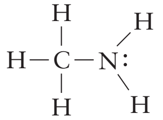


(a)

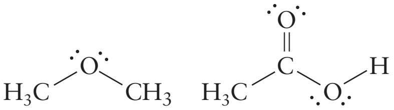


(b)

19.71 (a)



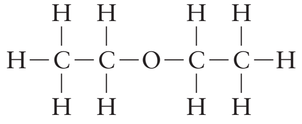
Methylamine



Dimethyl ether Acetic acid

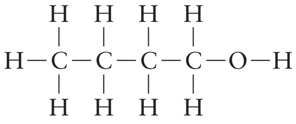
(b) methylamine: $-27.94\ kJ \cdot g^{-1}$; dimethyl ether: $-17.84\ kJ \cdot g^{-1}$; acetic acid: $-11.36\ kJ \cdot g^{-1}$; (c) dimethyl ether

19.73 (a)



Diethyl ether

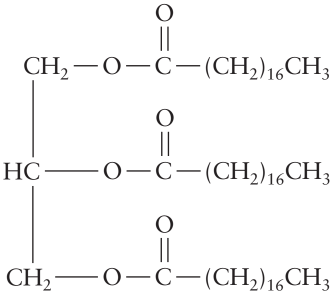
(b)



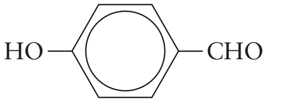
1-Butanol

1-Butanol can hydrogen bond with itself but diethyl ether cannot, so 1-butanol molecules are held together more strongly in the liquid and therefore 1-butanol has the higher boiling point. Both compounds can form hydrogen bonds with water and therefore have similar solubilities.

19.75 (a)



(b)



19.77 (a) $HOCH_2CH_2OH + 2\ CH_3(CH_2)_{16}COOH \longrightarrow CH_3(CH_2)_{16}COOCH_2CH_2OOC(CH_2)_{16}CH_3 + 2\ H_2O$;
(b) $2CH_3CH_2OH + HOOCCOOH \longrightarrow CH_3CH_2OOCCOOCH_2\ CH_3 + 2\ H_2O$;

(c) $CH_3CH_2CH_2CH_2OH + CH_3CH_2COOH \xrightarrow{\Delta}$
$CH_3CH_2COOCH_2CH_2CH_2CH_3 + H_2O$

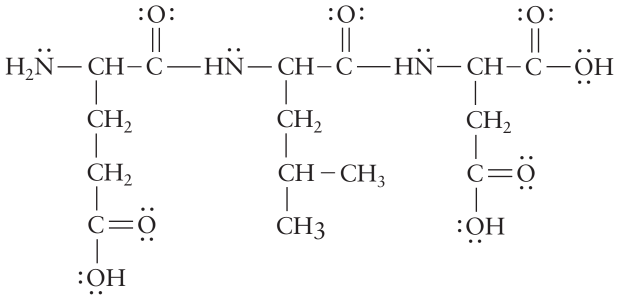
19.79 (a) 7180 g·mol^{-1}. (b) 135. (c) 23.75 Torr. (d) The osmotic pressure developed by the resulting polymer solution is readily measured, while the change in partial pressure of $H_2O(g)$ changes by less than 0.1% upon addition of the polymer.

19.81 (a) Primary structure is the sequence of amino acids along a protein chain. Secondary structure is the conformation of the protein, or the manner in which the chain is coiled or layered, as a result of interactions between amide and carboxyl groups. Tertiary structure is the shape into which sections of the proteins twist and intertwine, as a result of interactions between side groups of the amino acids in the protein. If the protein consists of several polypeptide units, then the manner in which the units stick together is the quaternary structure. (b) The primary structure is held together by covalent bonds. Intermolecular forces provide the major stabilizing force of the secondary structure. The tertiary structure is maintained by a combination of London forces, hydrogen bonding, and sometimes ion–ion interactions. The same forces are responsible for the quaternary structure.

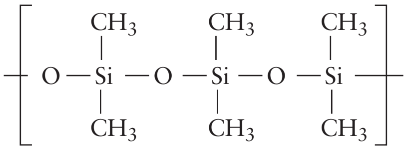
19.83 (a) $^+H_3NCH_2COOH(aq) + H_2O(l) \longrightarrow {}^+H_3NCH_2CO_2^-(aq) + H_3O^+(aq)$ $^+H_3NCH_2COO^-(aq) + H_2O(l) \longrightarrow H_2NCH_2COO^-(aq) + H_3O^+(aq)$
(b)$pK_{a1} = 2.35$, $pK_{a2} = 9.78$; pH = 2, $^+H_3NCH_2COOH$; pH = 5, $+ H_3NCH_2COO^-$; pH = 12, $H_2NCH_2COO^-$

19.85 Condensation polymerization involves the loss of a small molecule, often water or HCl, when monomers are combined. Dacron is more linear than the polymer obtained from benzene-1,2-dicarboxylic acid and ethylene glycol, so Dacron can be more readily spun into yarn.

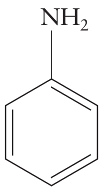
19.87



19.89



19.91 (a)



(b) sp^3. (c) sp^2. (d) Each N atom carries one lone pair of electrons. (e) Yes, the N atoms help to carry the current because the unhybridized p-orbital on each N atom is part of the extended π conjugation (delocalized π-bonds) that allows electrons to move freely along the polymer.

19.93 Two peaks are observed with relative overall intensities 3:1. The larger peak is due to the three methyl protons and is split into two lines with equal intensities. The smaller peak is due to the proton on the carbonyl carbon atom and is split into four lines with relative intensities 1:3:3:1.

19.95 The peaks in the spectrum can be assigned on the basis of the intensities and the coupling to other peaks. The hydrogen atoms of the CH_3 unit of the ethyl group will have an intensity of 3 and will be split into a triplet by the two protons on the CH_2 unit. This peak is found at $\delta \approx 1.2$. The CH_2 unit will have an intensity of 2 and will be split into a quartet by the three protons on the methyl group. This peak is found at $\delta = 4.1$. The CH_2 group that is part of the butyl function will have an intensity of 2 but will appear as a singlet because there are no protons on adjacent carbon atoms. This is the signal found at $\delta = 2.1$. The remaining CH_3 groups are equivalent and also will not show coupling. They can be attributed to the signal at $\delta = 1.0$. Notice that the peak that is most downfield is the one for the CH_2 group attached directly to the electronegative oxygen atom, and that the second most downfield peak is the one attached to the carbonyl group.

19.97 2-chloropropane

19.99 (a) ^{13}C . (b) 1.11% . (c) No; the reason is that the probability of finding two ^{13}C nuclei next to each other is very low. A ^{12}C nucleus next to a ^{13}C nucleus will not interact with the ^{13}C nucleus because the ^{12}C nucleus has no spin. Because the natural abundance of ^{13}C is 1.11%, the probability of finding two ^{13}C nuclei next to each other in an organic molecule will be 0.0111×0.0111 or 1.23×10^{-4}. Although such coupling is possible, it is generally not observed because the signal is so much weaker than the signal due to the molecules with a single ^{13}C nucleus. (d) Maybe; because most of the carbon to which the protons are attached is ^{12}C, the bulk of the signal will not be split. The protons that are attached to the ^{13}C atoms will be split, but this amounts to only 1.11% of the sample, so the peaks are very small. Peaks that result from coupling to a small percentage of a magnetically active isotope are referred to as satellites and may be observed if one has a very good spectrum. (e) Yes; although the splitting of protons by ^{13}C may not be observed because the amount of ^{13}C present is low, the opposite situation is not true. If a ^{13}C is attached to H atoms, the large majority of those H atoms will have a spin and so the ^{13}C will show fine structure due to splitting by the H atoms.

19.101 (a) 1. (b) 1. (c) 1. (d) 2. (e) Free rotation around the C—C and C—Cl bonds averages out the environments so that both CH_2 hydrogens are equivalent and all three CH_3 hydrogens are equivalent, resulting in just two different hydrogen signals.

KEY EQUATIONS

1. General

Roots of the equation $ax^2 + bx + c = 0$:

$$x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}$$

Kinetic energy of a particle:

$$E_k = \frac{1}{2}mv^2$$

Gravitational potential energy:

$$E_p = mgh$$

Coulomb potential energy of two charges Q_1 and Q_2 at a separation r:

$$E_p = Q_1Q_2/4\pi\varepsilon_0 r$$

2. Structure and spectroscopy

Relation between the wavelength, λ, and frequency, ν, of electromagnetic radiation:

$$\lambda\nu = c$$

Energy of a photon of electromagnetic radiation of frequency ν:

$$E = h\nu$$

de Broglie relation:

$$\lambda = h/p$$

Heisenberg uncertainty principle:

$$\Delta p \Delta x \geq \frac{1}{2}\hbar$$

Energy of a particle of mass m in a one-dimensional box of length L:

$$E_n = n^2h^2/8mL^2 \quad n = 1, 2, \ldots$$

Bohr frequency condition:

$$h\nu = E_{upper} - E_{lower}$$

Energy levels of a hydrogenlike atom of atomic number Z:

$$E_n = -Z^2h\mathcal{R}/n^2, n = 1, 2, \ldots$$

Formal charge

$$FC = V - \left(L + \frac{1}{2}S\right)$$

3. Thermodynamics

Ideal gas law:

$$PV = nRT$$

Expansion work against constant external pressure:

$$w = -P_{ex}\Delta V$$

Work of reversible, isothermal expansion of an ideal gas:

$$w = -nRT \ln (V_{final}/V_{initial})$$

First law of thermodynamics:

$$\Delta U = q + w$$

Definition of entropy change:

$$\Delta S = q_{rev}/T$$

Definition of enthalpy

$$H = U + PV$$

Definition of Gibbs free energy

$$G = H - TS$$

Change in Gibbs free energy at constant temperature:

$$\Delta G = \Delta H - T\Delta S$$

Relation between the constant-pressure and constant-volume molar heat capacities of an ideal gas:

$$C_{P,m} = C_{V,m} + R$$

Standard reaction enthalpy ($X = H$) and Gibbs free energy ($X = G$) from standard enthalpies and Gibbs free energies of formation:

$$\Delta X° = \Sigma\, n\Delta X_f°(\text{products}) - \Sigma\, n\Delta X_f°(\text{reactants}), n \text{ in moles}$$
$$\Delta X_r° = \Sigma\, n\Delta X_f°(\text{products}) - \Sigma\, n\Delta X_f°(\text{reactants}), n \text{ dimensionless}$$

Standard reaction entropy:

$$\Delta S° = \Sigma\, nS_m°(\text{products}) - \Sigma\, nS_m°(\text{reactants}), n \text{ in moles}$$
$$\Delta S_r° = \Sigma\, nS_m°(\text{products}) - \Sigma\, nS_m°(\text{reactants}), n \text{ dimensionless}$$

Kirchhoff's law:

$$\Delta H_2° = \Delta H_1° + \Delta C_P(T_2 - T_1)$$

Change in entropy when a substance of constant heat capacity, C, is heated from T_1 to T_2:

$$\Delta S = C \ln (T_2/T_1)$$

Change in entropy when an ideal gas expands isothermally from V_1 to V_2:

$$\Delta S = nR \ln (V_2/V_1)$$

Boltzmann's formula for the statistical entropy:

$$S = k \ln W$$

Entropy change of the surroundings for a process in a system with enthalpy change ΔH:

$$\Delta S_{surr} = -\Delta H/T$$

4. Equilibrium and electrochemistry

Definition of activity (for ideal systems):

For an ideal gas: $a_J = P_J/P°$, $P° = 1$ bar

For a solute in an ideal solution: $a_J = [J]/c°$, $c° = 1\ mol \cdot L^{-1}$

For a pure liquid or solid: $a_J = 1$

Reaction quotient and equilibrium constant:

For the reaction $a\,A + b\,B \longrightarrow c\,C + d\,D$, $Q = a_C{}^c a_D{}^d / a_A{}^a a_B{}^b$

For the equilibrium $a\,A + b\,B \rightleftharpoons c\,C + d\,D$,
$K = (a_C{}^c a_D{}^d / a_A{}^a a_B{}^b)_{equilibrium}$

Variation of Gibbs free energy of reaction with composition:

$$\Delta G_r = \Delta G_r° + RT \ln Q$$

Relation between standard reaction Gibbs free energy and equilibrium constant:

$$\Delta G_r° = -RT \ln K$$

van 't Hoff equation:

$$\ln \frac{K_2}{K_1} = \frac{\Delta H_r°}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

Relation between K and K_c:

$$K = (RTc°/P°)^{\Delta n_{gas}} K_c \qquad P°/Rc° = 12.03 \text{ K}$$

Clausius–Clapeyron equation:

$$\ln \frac{P_2}{P_1} = \frac{\Delta H_{vap}°}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

Relation between Gibbs free energy and maximum nonexpansion work:

$$\Delta G = w_{e,max} \text{ at constant temperature and pressure}$$

Relation between pH and pOH:

$$pH + pOH + pK_w$$

Relation between acidity and basicity constants of a conjugate acid–base pair:

$$pK_a + pK_b = pK_w$$

Henderson–Hasselbalch equation:

$$pH = pK_a + \log ([\text{base}]_{initial}/[\text{acid}]_{initial})$$

Relation between the Gibbs free energy of reaction and the cell potential:

$$\Delta G = -nFE_{cell}$$

Relation between the equilibrium constant for a cell reaction and the standard cell potential:

$$\ln K = nFE_{cell}°/RT$$

Nernst equation:

$$E_{cell} = E_{cell}° - (RT/nF) \ln Q$$

5. Kinetics

Average reaction rate:

$$\text{Rate of consumption of R} = -\frac{\Delta[R]}{\Delta t}$$

$$\text{Rate of formation of P} = \frac{\Delta[P]}{\Delta t}$$

Unique average rate for $a\,A + b\,B \longrightarrow c\,C + d\,D$

$$\text{Unique average reaction rate} = -\frac{1}{a}\frac{\Delta[A]}{\Delta t} = -\frac{1}{b}\frac{\Delta[B]}{\Delta t} = \frac{1}{c}\frac{\Delta[C]}{\Delta t} = \frac{1}{d}\frac{\Delta[D]}{\Delta t}$$

Integrated rate laws:

For Rate of disappearance of A $= k[A]$,

$$\ln \frac{[A]_t}{[A]_0} = -kt, [A]_t = [A]_0 e^{-kt}$$

For Rate of disappearance of A $= k[A]^2$,

$$\frac{1}{[A]_t} - \frac{1}{[A]_0} = kt, \quad [A]_t = \frac{[A]_0}{1 + [A]_0 kt}, \quad \frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$$

Half-life of a reactant in a first-order reaction:

$$t_{1/2} = (\ln 2)/k$$

Arrhenius equation:

$$\ln = \ln A - E_a/RT$$

The rate constant at one temperature in terms of its value at another temperature:

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

The equilibrium constant in terms of the rate constants:

$$K = k_{forward}/k_{reverse}$$

THE ELEMENTS

RELATIONS BETWEEN UNITS*

Property	Common unit	SI unit
Mass	2.205 lb (lb = pound)	1.000 kg
	1.000 lb	453.6 g
	1.000 oz (oz = ounce)	28.35 g
	1.000 ton (= 2000 lb)	907.2 kg
	1 t (t = tonne, metric ton)	**10^{3} kg**
Length	1.094 yd (yd = yard)	1.000 m
	0.3937 in. (in. = inch)	1.000 cm
	0.6214 mi (mi = mile)	1.000 km
	1 in.	**2.54 cm**
	1 ft (ft = foot)	**30.48 cm**
	1.000 yd	0.9144 m
	1 Å (Å = ångström)	**10^{-10} m**
Volume	**1 L (L = liter)**	**$10^{3}\ cm^{3}$, 1 dm^{3}**
	1.000 gal (gal = gallon)†	3.785 dm^{3} (3.785 L)
	1.00 ft^{3} (ft^{3} = cubic foot)	$2.83 \times 10^{-2}\ m^{3}$ (28.3 L)
	1.00 qt (qt = quart)†	$9.46 \times 10^{2}\ cm^{3}$ (0.946 L)
Time	**1 min (min = minute)**	**60 s**
	1 h (h = hour)	**3600 s**
	1 day	**86 400 s**
Pressure	**1 atm (atm = atmosphere)**	**$1.013\,25 \times 10^{5}$ Pa**
	1.000 Torr or 1.000 mmHg	133.3 Pa
	1.000 psi (psi = pounds per square inch)	6.895 kPa
	1 bar	**10^{5} Pa**
Energy	**1 cal**	**4.184 J**
	1 eV	1.60218×10^{-19} J; 96.485 $kJ \cdot mol^{-1}$
	1 C·V	**1 J**
	1 kWh (kWh = kilowatt hour)	**3.600×10^{3} kJ**
	1 L·atm	**101.325 J**

Temperature conversions

(Fahrenheit temperature)/°F = $\frac{9}{5}$ × (Celsius temperature)/°C + **32**

(Celsius temperature)/°C = $\frac{5}{9}$ ×{(Fahrenheit temperature)/°F − **32**}

(Kelvin temperature)/K = (Celsius temperature)/°C + **273.15**

*Entries in boldface type are exact.

†The European and Canadian Imperial quart and gallon are 1.201 times as large.
